Sicily was again a battlefield between 43 and 36 B.C., when Sextus Pompeius held Messana and cut off the corn supply of Rome. In the division of provinces between Augustus and the senate, Sicily fell to the latter. It had perhaps received Latin rights from Julius Caesar. Augustus planted colonies at Panormos, Syracuse, Tauromenium, Thermae, Tyndaris and Catania. But the island remained Greek; not only the old Greek cities but also the old Sicel towns, which had long been completely assimilated to the Greek, used Greek as their everyday language, though Latin was the official language. Christianity was early introduced to Syracuse, where the catacombs and early churches (belonging mainly to the Byzantine period) are second only to those of Rome. The island has little history in the Roman imperial period; its continued prosperity is shown by the Roman amphitheatres of Syracuse and Catania and by Roman remains in other cities large and small; a few cities declined and show now only Greek remains, but these were in general replaced by others. The tourist traffic in Sicily is as old as the Roman period. Cicero praises the climate of Syracuse, and the emperor Hadrian climbed Etna in A.D. 126 to see the sunrise. In the late 3rd century a rich Roman, perhaps a high court official, perhaps even an emperor (the name of Maximian has been suggested), retired and built a huge villa, with floor mosaics with lively pagan scenes, near the modern town of Piazza Armerina. In the reorganization of the late 3rd–early 4th century Sicily became one of the provinces of Italy and, together with Africa, Raetia and western Illyricum, was made part of the Italian prefecture; with Sardinia and Corsica, it was part of the diocese of Italy and the vicariate of Rome. (T. J. DN.; X.)

4. The Byzantine Period, to 827.—The earlier Germanic invaders of the Roman empire did not reach Sicily, though Alaric had designs upon it. The Vandals under Gaiseric, however, raided and invaded Sicily from Africa for about 40 years intermittently until in 476 they ceded the greater part of it to Odoacer, the barbarian king of Italy, against the payment of an annual tribute. The Ostrogothic successors of the latter paid no tribute to the Vandals after 491, but Theodoric gave Lilybaeum to the Vandal king Trasamund, to whom his daughter Amalafrida was married in 500. The Byzantine general Belisarius, having destroyed the Vandal kingdom in 533–534, occupied Sicily in 535, when his emperor began hostilities against the Ostrogoths in Italy; and though Totila recovered part of the island in 550, it was lost again before the final overthrow of the Ostrogothic kingdom at Taginae (552).

Sicily had thus come under Byzantine rule. When the emperor Heraclius and his successors divided the empire into themes (provinces), Sicily became one of them, placed between the exarchate of Ravenna in the north and that of Carthage in the south; it was administered by a *patricius* responsible to the government at Constantinople. Probably after the Italian revolt of 726 and certainly after the fall of the exarchate in the middle of the 8th century, the Byzantine dominions in southern Italy were incorporated in the theme of Sicily, an arrangement which lasted until the time of the Arab conquest, when the mainland dominions were formed into the themes of Calabria and Longobardia.

Ecclesiastically, Sicily remained at first under the papacy, which in addition to rights of jurisdiction had considerable interests in the island, arising from its vast Sicilian estates. Gregory I's letters admirably illustrate the importance attached to them by the pope. The Iconoclastic controversy and the ensuing revolt against Byzantine rule under papal leadership (726) led to the confiscation by the emperor of the papal estates in Sicily and southern Italy; soon after, the ecclesiastical jurisdiction of these regions passed to the patriarch of Constantinople.

These political and ecclesiastical changes corresponded to demographic and cultural developments of longer standing. In Sicily and southern Italy, the Greek element had been greatly strengthened since the end of the 6th century as a result of emigration from other Byzantine provinces after the Avar and Slav invasions of Greece and, later, of the Persian and Arab conquests. The hellenization of Sicily, which appears to have been all but complete in the 8th century, is revealed in the history of the Sicilian Church. The Greek rite, already used at the time of Gregory I, spread during the 7th century from the eastern coast over the whole of the island. By the time of its separation from Rome, the Sicilian Church was virtually Greek. Sicily was thus well on the way to becoming a fully integrated part of the Byzantine empire when the Arab conquest began in 827.

Ever since the 7th century, Arab expansion in North Africa had constituted an immediate threat to Sicily and to southern Italy, the occupation of which would moreover expose Greece, the exarchate of Ravenna and Dalmatia to Saracen attack. Sicily consequently became a vital link in the imperial defense against Islam. Constans II was the first Byzantine emperor fully to appreciate this; in 663–668 he tried to strengthen the Byzantine position in Sicily by his own presence. Constans, however, was assassinated during a rebellion at Syracuse in 668. Mizizes (Mezezius) who was then proclaimed emperor by the Byzantine militia, fell from power in 669.

This rebellion was followed by other risings in Sicily in 718 and in 781, which, although primarily of a military nature, doubtless also reflected separatist tendencies. A more dangerous revolt, that of the naval commander Euphemius about 826, was to be the immediate cause of the Arab conquest of Sicily.

5. The Arabs.—Following the conquest of North Africa, Arab descents from Africa began in 703. They were interrupted for the invasion of Spain (710), and the next serious attacks were probably not made before 740 and 752–753. Energetic Byzantine reaction on this last occasion was followed by a respite lasting more than 50 years. But in 827 Euphemius, who had been proclaimed emperor in Sicily, appealed for help to the Aghlabid amir of Africa. But once the Arabs had landed they began the conquest on their own account. Euphemius was murdered by Sicilians in 828; and Palermo fell in 831 and became the base for further conquests. When a stronger policy was adopted under the emperor Michael III, it was too late; after the Byzantine defeat near Butera in *c.* 845, the whole of the Val di Noto fell into Arab hands; its occupation was practically completed with the capture of Enna in 859. A Byzantine offensive under Basil I led to some temporary successes, but the fall of Syracuse in 878 all but sealed the fate of Sicily; when they captured Taormina in 902, the Arabs were practically masters of Sicily. Local resistance and insurrections, however, continued. Together with internal discords in the Arab camp they did much to slow up the Arab advance, despite the scant help from Constantinople. The Val Demone (*i.e.*, the region between Etna, Messina and Caronia) held out longest; and the last Byzantine stronghold, Rametta, was not lost until 965. The Byzantines, however, did not abandon hope of reconquering Sicily. Basil II was planning a Sicilian expedition at the time of his death (1025); it was actually dispatched in 1038 under the great Byzantine general, George Maniaces. The campaign was highly successful, and a large part of eastern Sicily, including Messina and Syracuse, was recaptured; but after Maniaces was suddenly recalled, the Byzantine position on the island collapsed.

The Arab conquest separated Sicily not only from Constantinople but also from the Italian mainland, where the Arabs did not succeed in establishing themselves permanently. The history of Arab Sicily, on the other hand, was marked by growing independence from Africa. Until 909, it was under the Aghlabids; after their fall, it passed under the Fatimids, who moved their capital to Cairo in 972. But from the middle of the 10th century the office of the governor (amir) became hereditary in the dynasty of the Kalbids, until the anarchy after Maniaces' conquests led

to the fall of that dynasty and to the division of Sicily into a number of principalities, while Palermo acquired self-government.

During and after the conquest, large Arab immigration from Africa took place; this, together with the conversions of Christians, contributed to make Sicily not only politically but also culturally part of the Arab world. However, the Greek Christian element remained predominant in the Val Demone; and even after the Arabs gained a majority in the rest of Sicily, Christian groups remained scattered over the island.

As in other Arab countries, the Christians, although placed in a position of legal inferiority, enjoyed religious toleration and a measure of self-government in return for paying taxes which may have been often less burdensome than those levied by the Byzantines. Relics of the Greek episcopate seem to have survived to the end of the Arab period; so did a number of Basilian monasteries; both provided the principal link with the Byzantine world outside (particularly with Calabria, where the Greek population had been strengthened by emigrants from Sicily). As far as the Sicilian clergy, secular and regular, was concerned, this emigration seems to have been less the result of persecutions than of the gradual spread of Islam over Sicily.

6. The Norman Conquest: Roger I.—When the Normans began to conquer Sicily in 1060, they were welcomed as liberators and their progress was doubtless assisted by the Christian population. They were no newcomers to the island. Norman mercenaries from the mainland, among them two sons of Tancred of Hauteville, had fought in Maniaces' army and taken part in the capture of Messina. In 1059 Pope Nicholas II invested another son of Tancred, Robert (*q.v.*) Guiscard, with his past and future conquests not only in Apulia and Calabria but also in Sicily. In his oath of allegiance Robert styled himself "by the grace of God and St. Peter duke of Apulia and Calabria and, with their help, hereafter of Sicily." (*See* NAPLES, KINGDOM OF.)

The conditions under which the Norman expedition took place were to leave a profound mark on the history of Sicily. The papal enfeoffment of Robert with Sicily may have been legally contestable—it was naturally not recognized by Constantinople—but it forged a link between the papacy and Sicily which long outlasted Norman rule.

It was Robert's brother, Count Roger I (*q.v.*), who as the former's vassal and with his assistance became the real conqueror of Sicily. Internal conflicts among the Arabs served him well. The amir of Syracuse and Catania, at war with his brother-in-law, the amir of Girgenti (Agrigento) and Castrogiovanni (as Enna came to be called), went so far as to offer Roger his help to conquer the island. The first landing (1060), near Messina, was followed by an equally inconclusive attack on that town in 1061; the third, made in greater strength and with the participation of Robert, succeeded (summer, 1061). The possession of Messina gave the Normans control of the straits and a military base for further advance; the capture of Palermo (1072) concluded the first phase of the conquest; and the capture of Noto (1091) completed it. Although Robert's assistance was at first all-important, Roger soon assumed the leading role. After the conquest Robert probably retained only Palermo—apart from the suzerainty over the whole island, which suzerainty became entirely nominal under Roger Borsa, Robert's weak successor as duke of Apulia (1085–1111), who in 1091 surrendered half of Palermo to his uncle.

If Roger was the real conqueror of Sicily, he was also the founder of the Norman Sicilian state. By distributing fiefs sparingly, he gave feudalism a less important place in Sicily than it had acquired on the mainland, where Robert Guiscard had established his ducal power by making the Normans accept him as their ruler. At the same time he accepted much of the existing law and institutions. In his treatment of the Arab majority, his policy of religious toleration resembles that previously practised by the Arabs. Their legal conditions varied considerably, ranging from the liberties that they enjoyed at Palermo, where they had their own quarter and mosques, to the serfdom of the mass of the country population. Roger made use of their military and administrative services; many leading Arabs, however, seem to have left the country after the conquest.

Roger showed much favour to the Greeks, as appears from his lavish patronage of Basilian monasticism. He founded or restored at least 14 Greek monasteries as against 4 Benedictine ones. The Norman conquest was followed by an increase of the Greek population, Basilian monks from Calabria forming only one element of the new immigration. The Sicilian Church, however, became Latin, according to the promise made by Robert Guiscard to Pope Nicholas II in 1059. But the papacy was left only little influence in it; the concession of the apostolic legation to Roger (1098) made the Sicilian Church practically independent of Rome by sanctioning an already existing state of monarchical control.

7. Roger II and the Foundation of the Kingdom.—The survival of Roger I's work during the difficult period after his death (1101) was a measure of his success. Roger's son and heir Simon died in 1105 and was succeeded by his brother Roger II (*q.v.*); but their mother Adelaide ruled as regent from 1101 until Roger attained his majority in 1112. Roger continued his father's efforts to take advantage of the difficulties of the duke of Apulia (Roger Borsa had been succeeded by his son William in 1111), not only eliminating the last relic of ducal authority on the island by obtaining the second half of Palermo in 1122 but also extending his lands and influence in the duchy of Apulia and in Calabria. After Duke William's death in 1127, Roger II crossed over to the mainland to assert his claims as his heir.

Roger's expedition opens a period of struggles which lasted until 1139. His claims were opposed not only by many lords and towns but also, until 1128, by Pope Honorius II. By supporting the antipope Anacletus II against Innocent II, Roger obtained the royal title for Sicily, Apulia and Calabria (1130). But this led to an alliance of Innocent II and the emperor Lothair against the ruler who by his support of the antipope was primarily responsible for the prolongation of the schism. Lothair's invasion of the kingdom in 1136 in alliance with Pisa and Venice and, perhaps, Byzantium brought Roger's fortunes to their lowest point. But after Lothair's withdrawal, Roger soon recovered lost ground; and after the death of Anacletus (1138), Innocent II confirmed him in the royal title. The treaty of Mignano (1139) meant the final acknowledgment by the papacy of the Norman kingdom, which included the mainland provinces of Apulia, Calabria and Capua as well as Sicily.

The political problems of the kingdom were, to no small extent, a legacy of the different territories of which it was formed. Thus the conflicts with the German and Byzantine emperors belong largely to the history of the South Italian provinces; while Roger's and his successors' African policy is rooted in the earlier history of Sicily. The first expeditions against the Zirid prince of Mahdia in North Africa (1118, 1123) were failures; but in 1134–35 internal discords in the Zirid state provided Roger with fresh opportunities for intervention, which was facilitated by the growth of the Sicilian navy; the expedition led to the occupation of the island of Djerba. The capture of Tripoli in 1146 initiated a series of conquests which culminated in that of Mahdia in 1148; by that year, Roger's African empire extended from Tripoli to Tunis, from the desert of Barca to Kairouan. That it was short-lived was primarily due to the failure to check the growing power of the Almohads; and the death of the grand admiral George of Antioch, the conqueror of Africa, in 1151–52 and that of Roger II in 1154 jeopardized its survival. The crisis was to begin in 1156 with an Arab rising in Africa; by 1160, the African empire was lost. The Norman kings, however, did not abandon their African ambitions: William II was to send a fleet to lay siege to Alexandria in 1174, and further expeditions were to be undertaken against the North African coast in the following years.

Expansion in Africa had sharpened the antagonism between Norman Sicily and Constantinople. At first, when the Byzantines had received support from the Western emperors, the alliance of the two empires constituted a formidable threat to the Sicilian kingdom; but the clash between Byzantine and Western imperial claims led, after Frederick I Barbarossa's Roman coronation (1155), to the end of the alliance, Frederick continuing an anti-Norman policy of his own. Roger took the initiative against the Byzantines in 1147 and 1149, seized Corfu and invaded Greece. The Byzantines, on the other hand, reconquered part of Apulia in

1155, after Roger's death; but they lost the conquered territories again after their crushing defeat at Brindisi (1156). Peace was concluded in 1158 and was not broken until 1185, when King William II invaded the Byzantine empire, took Durazzo (Durres) and Thessalonica (modern Salonika) and advanced toward Constantinople, with the ultimate aim of seizing the Eastern imperial crown. But the counteroffensive under the new emperor Isaac II Angelus put an end to this expedition. It was the last great enterprise of the Norman kings.

8. Internal Development of Norman Sicily.—Roger II's internal policy was based on that of his father and was continued by his son William I (*q.v.;* 1154–66) and by the latter's son William II (*q.v.;* 1166–89); but his own contribution to the building of the Sicilian state was very great. The combination of Norman, Arabic and Byzantine elements is perhaps the most striking but at the same time a very natural characteristic of the government and civilization of the kingdom. Roger's Assizes of Ariano (1140) derive largely from Justinian and later Byzantine law; very strong Byzantine influence can be found in the judicial and fiscal administration and in the central financial department, the *duana* (diwan), the personnel of which was originally Arabic. The Norman chancery issued documents in Latin, Greek and Arabic. On the other hand, the curia was primarily modeled on that of the northern European states; and not only were feudal institutions accepted but feudal barons also played an important part in the provincial and local administration. At the same time, some of the most influential ministers of the Norman period, the grand admirals such as George of Antioch were Greeks. Roger's capital was cosmopolitan Palermo.

But despite the role played by Greeks and Arabs in the bureaucracy, Sicily became progressively latinized. While the Muslim population was decreased by conversions, the Latin element was strengthened by the settlement of colonies of "Lombards" (*i.e.,* mainlanders), Greeks and Arabs being gradually reduced to small minorities. This process is also reflected in the large number of Latin monasteries founded by the kings, after the initial favour shown to the Basilian monks. But Sicilian civilization retained the composite character that it had possessed from the beginning; Sicilian scholars translated Greek classical texts into Latin; Idrisi, on the orders of Roger II, composed one of the outstanding works of Arab geography; and Sicilian architecture was the product of Roman, Byzantine, Arabic and Norman influences.

9. The Hohenstaufen Accession.—William II's death (1189) was followed by a struggle for the succession. William I and William II had long supported Pope Alexander III in his conflict with Frederick Barbarossa; but a truce had been concluded in 1177 and the subsequent rapprochement between king and emperor had resulted in William II's sanctioning the betrothal of Frederick's son Henry to Constance, daughter of Roger II and heiress apparent to the kingdom (1184; marriage 1186). This created a situation of great potential danger for the papacy, as it strengthened imperial claims on the kingdom of Sicily by the addition to them of Constance's rights. On William's death, however, there was strong Norman opposition to the prospect of German rule, and Tancred (*q.v.*), an illegitimate grandson of Roger II, was crowned king. Frederick's son, who had succeeded his father as Henry VI, failed to make good his claims in 1191, when he was forced to raise the siege of Naples; but the sudden death of Tancred early in 1194 proved a turning point. The reign of his young son, William III, under the regency of Queen Sibylla lasted only ten months; Henry VI finally occupied the kingdom and was crowned king at Palermo in 1194. A new period in the history of Sicily had begun.

Henry aimed at including Sicily permanently in the empire, which he unsuccessfully tried to make hereditary in his family, the house of Hohenstaufen; and the distribution of high offices and lands among his followers was to strengthen his control of the kingdom. His death in 1197 temporarily put an end to imperial domination. Constance, as ruler with her young son, the future emperor Frederick II (*q.v.*), returned to a strictly Norman policy. But she died in 1198, leaving Frederick under the guardianship of Pope Innocent III. The following years were marked by growing anarchy, due to the weakness of the monarchy, to the attempts of German lords to seize hold of the kingdom, to the Arabs' endeavours to improve their position and to the commercial expansion of Pisa and Genoa. After Frederick had reached his majority (1208), Innocent handed the government over to him.

10. The Emperor Frederick II (Frederick I of Sicily).—In 1211 Pope Innocent saw himself forced to support Frederick's renewed election as king of the Romans or as German king. Frederick promised Innocent, just before the latter's death in 1216, to renounce the Sicilian kingdom in favour of his son Henry after his imperial coronation; but the papacy's hope to prevent in this way the reunion of Sicily and the empire was not fulfilled, for in 1220 Frederick succeeded in having Henry elected German king. The eventual union of the German and Sicilian crowns, foreshadowed by this election, made papal insistence on Frederick's renunciation obsolete; and when Frederick was crowned emperor in the same year, Honorius III tacitly recognized him also as Sicilian king.

Frederick devoted the following years to the restoration of royal power in the kingdom; and in this formidable task he revealed himself the true successor of Roger II. In Sicily Frederick acted as Norman rather than German ruler: symptomatically, his edict on the resignation of privileges (1220) put the deadline at the death of William II, not of Henry VI. His preoccupation with the affairs of the kingdom was largely responsible for the postponements of his crusade, which led in 1227 to his excommunication. Papal troops invaded the kingdom during his absence in Palestine (1228–29); but Frederick's return meant his immediate victory, and the peace of San Germano (1230) was followed by further internal reforms. The Constitutions of Melfi (1231), a legal code inspired by Roger II's Assizes, give a remarkable insight into the organization of the kingdom and also into the political ideas of its ruler. Frederick carried the evolution of the Sicilian administration considerably beyond what had been achieved by the Normans; on the other hand, the use that he made of assemblies of estates, including municipal representatives (from 1232), was a landmark in the history of the Sicilian parliament. In his highly centralized government Frederick was the heir to his Norman predecessors, whose work he continued. The same continuity can also be seen in Sicilian culture, but at Frederick's brilliant cosmopolitan court Italian poetry provided a new formative element.

11. The End of Hohenstaufen Rule.—Frederick's work was jeopardized and his dynasty ruined by the union of Sicily with the empire. The conflicts with the papacy and with its allies, the Lombard communes, meant a serious strain on the Sicilian economy and started a chain of events which was finally to lead to the establishment of the house of Anjou in the kingdom. Innocent IV, having declared Frederick deposed from the imperial throne (1245), wanted to deprive him and his descendants of the Sicilian crown as well. Frederick's death in 1250 and that of his son Conrad IV in 1254 provided the papacy with new opportunities, but the success of Manfred (*q.v.*), one of Frederick's illegitimate sons, in establishing control over the kingdom even before Conrad's death complicated the situation and gave rise to lengthy and tortuous negotiations in which papal offers of the Sicilian crown to foreign princes alternated with rapprochements to Conrad and to Manfred. Manfred was crowned king at Palermo in 1258—a usurpation of the rights of Conradin, Conrad IV's young son and heir. In 1263 after negotiations with Manfred had broken down for the last time Pope Urban IV announced the choice of Charles of Anjou (see CHARLES I of Naples), brother of Saint Louis, as king of Sicily (Edmund Lancaster, son of Henry III of England, who had been invested by the papacy with the kingdom in 1255, had failed to substantiate his claims). In 1265 Charles was invested with the kingdom by Pope Clement IV in Rome; near Benevento, in 1266, he defeated Manfred, who was killed.

12. Charles of Anjou.—After Benevento there was no serious resistance to Charles in the kingdom. But his rule had still to stand its test when Conradin came to Italy in 1267 to seize his inheritance. A rising in his favour swept the kingdom and showed the fragility of Charles's position. In 1268, however, Conradin was defeated at Tagliacozzo and executed at Naples. There followed severe suppression of the revolt, especially in Sicily, where

it had been more widespread than on the mainland. Charles tried to put his power on a firm foundation by a large-scale distribution of fiefs among his French nobility. At the same time he preserved, in its main outlines, Frederick's system of government. The "French colonization," however, and the sense of grievance that it caused among the Sicilians was partly responsible for the great revolt of 1282, known as the Sicilian Vespers (*q.v.*), which severed Sicily once more from the mainland. (N. R.)

13. The Aragonese.—The revolt of the Vespers precipitated the arrival in Sicily of Peter III of Aragon, who had a claim to the crown through his marriage (1262) to the Hohenstaufen heiress Constance, Manfred's daughter. The Sicilians, however, were jealous of their independence: it had been only after the papacy had rebuffed their appeal for recognition of a communal regime of their own that they had addressed themselves to Peter. While Peter was accepted as king (Peter I), Constance governed the island for him till his death in 1285; but then, whereas their eldest son succeeded to Aragon as Alfonso III, the Sicilian crown was transmitted to their second son, who became James I of Sicily. The termination of the personal union between Aragon and Sicily was gratifying to Sicilian separatist feeling, but its effect was prejudiced when Alfonso, having already deserted the Sicilian side in the continuing War of the Sicilian Vespers, died without issue in 1291. In his will he had stipulated that if his brother James were to succeed him in Aragon as James II, he should renounce Sicily to their youngest brother Frederick, in repetition of the previous arrangement; but James, heir to Aragon in his own right, would not at first be bound by this condition and simply nominated Frederick as his lieutenant in Sicily. Subsequently, however, he found that from Aragon's point of view it was indeed expedient to renounce the Sicilian connection; and by the treaty of Anagni (1295) he agreed to surrender Sicily to the papacy.

The Sicilians reacted against this new betrayal by taking Frederick as their king. Though in fact he was Frederick II of Sicily, he took the style of Frederick III (*q.v.*).

James II of Aragon allied himself with Charles II of Naples to execute the treaty of Anagni against the Sicilians, but the allies' efforts came to nothing; and the treaty of Caltabellotta (1302) brought the 20 years' War of the Vespers to an end: Frederick was to have the kingdom for his lifetime, after which it should revert to the Neapolitan Angevins. Pope Boniface VIII, whose predecessors had steadfastly opposed the Aragonese over Sicily, could only insist that Frederick should style himself "king of Trinacria" (*i.e.*, "of the Three-cornered Isle") instead of "king of the Island of Sicily."

The Angevin-Aragonese peace did not last long. Having taken the emperor Henry VII's side against Robert of Naples and the Guelphs, Frederick resumed the title "king of Sicily" and, in 1314, induced the Sicilian parliament to declare that on his death the crown should pass to his son Peter. Successive Neapolitan attacks on the island failed to reduce him, and on his death his son succeeded him as Peter II (1337).

Frederick's position had obliged him to rely on the support of the Sicilian parliament. He organized it as an assembly of three *bracci*, or houses, representing the feudatories, the clergy and the towns of the royal domain, on the model of the three estates of the kingdom of Aragon; and he associated it with himself in the exercise of sovereignty. Himself a strong ruler, he was able to keep his barons in order. Under his successors, however, the barons began to assert themselves both in encroachment on the royal authority and in internal warfare of their own; *e.g.*, between the "Latin" faction (the older Sicilian nobility) and the "Catalan" (the Aragonese newcomers) during the reign of King Louis, who was only four years old when he succeeded his father Peter II in 1342.

The next king, Frederick III (properly so numbered), who succeeded his brother Louis in 1355, managed to withstand renewed attacks by the Neapolitan Angevins (who occupied Messina for a short time in 1356) and finally came to terms with Joan I of Naples in 1373: she agreed that Sicily, officially called Trinacria again, should be a separate kingdom in vassalage both to the Holy See and to her own kingdom of Naples-Sicily.

Frederick III died in 1377, leaving a daughter, Mary, as his heiress. There ensued a long period of disorder. Peter IV of Aragon, on the grounds that the testament of Frederick III (II) precluded female succession to the Sicilian crown, claimed it for himself as the nearest male heir (he was also the father of Mary's mother and the husband of her aunt); and Mary underwent a series of abductions. Peter, however, in the face of objections from the papacy and the Angevins, in 1380 ceded his pretensions to his second son, Martin, duque de Montblanch, whose son Martin was to marry Mary. Peter IV died in 1387, leaving Aragon to his elder son John I; the queen of Sicily was brought to Spain in 1388; and her marriage to the younger Martin took place in 1390. In 1392 the couple landed in Sicily with Martin of Montblanch and began to reign as queen and king-consort, despite strong local opposition. Mary died in 1401, leaving her widower to reign alone as Martin I of Sicily; but meanwhile the duque de Montblanch had become king of Aragon as Martin I in 1395 through the death of John I. When Martin I of Sicily died without legitimate issue in 1409, he left his kingdom, with his second wife Blanche of Navarre as regent, to his father, who thus became Martin II of Sicily.

Martin II, who had no surviving children of his own, intended that Sicily at least, if not Aragon too, should go to his grandson Fadrique (Frederick) de Luna, a bastard of Martin I of Sicily. On Martin II's death, however, in 1410, this succession was contested; and Ferdinand of Antequera, son of Peter IV's daughter Leonor, having been chosen king of Aragon as Ferdinand I in 1412, defeated Fadrique's partisans and re-established Blanche's authority as his regent in Sicily. Thenceforward the Aragonese (later the Spanish) and the Sicilian crowns were to remain united for nearly 300 years (till the War of the Spanish Succession).

Alfonso V of Aragon (I of Sicily), having succeeded his father Ferdinand I in 1416, used Sicily as his base for his expeditions to Naples during Joan II's precarious tenure of that kingdom; and the Aragonese conquest of Naples after Joan's death temporarily restored the personal union of the Neapolitan and Sicilian crowns. Alfonso, however, kept the two kingdoms theoretically separate, arranging as early as 1443 that his bastard son Ferdinand (Don Ferrante) was to inherit Naples, whereas Sicily passed at his death in 1458 to his brother John II of Aragon (John I of Sicily). John's son Ferdinand II (*q.v.*) finally recovered Naples for the legitimate line of Aragon (1503).

The dynastic troubles of the period 1337–1412 had further helped the Sicilian feudatories and the towns to extort privileges from the kings as the price of support. The royal lieutenants or viceroys who ruled for the Aragonese kings from 1415 had extensive powers, but still had always to reckon with the Sicilian parliament. By the middle of the 15th century it had become an accepted principle of the constitution of the kingdom that no new taxes should be levied without the parliament's consent; and this power of veto over subsidies to the king made the *bracci* a formidable obstacle to royal or viceregal absolutism, as well as to any attempt to reduce feudal, ecclesiastical or municipal privilege.

14. The Spanish Habsburgs.—Ferdinand II, dying in 1516, left Sicily, with Naples and all his Spanish inheritance, to his grandson, the Austrian Habsburg Charles I of Spain, who three years later became Holy Roman emperor as Charles V. The reign began with a rising (1516) of the privileged orders against the viceroy, Hugo de Moncada, whom Charles recalled without canceling the edicts that had provoked the trouble. A rising against the new viceroy, Ettore Pignatelli, duque de Monteleone, developed however into widespread outrages against the nobility, which reacted by co-operating with the viceroy. Thereafter the privileged orders in general professed themselves loyal to the distant monarchy, which stood as the guarantor of their privileges, while the viceroys had to bear the burden and the odium of actual government, raising the necessary taxes and trying to keep order in an island still prone to baronial vendetta and to jealous rivalries between town and town. The arrival of the Ottoman Turks in the western Mediterranean exposed Sicily to danger from a new quarter, and it became a base for the emperor's counterattacks on the North African coast.

In 1555 Charles V abdicated Naples to his son, the future Philip

II of Spain. Pope Paul IV then promoted a scheme whereby the French should conquer Naples for a prince of their own house and seize Sicily for the Venetians; but Philip, to whom Charles V had abdicated Spain and Sicily in 1556, forced the pope to recognize him in 1557 and secured peace from the French in 1559. The battle of Lepanto (1571) checked the gravest menace from Turkey.

Contributions from Sicily were required for Philip II's enterprises in western Europe and for the defense of Spanish interests in the west and in Italy during Philip III's reign (1598–1621). With the growth of the French challenge to Spain during Philip IV's reign (1621–65; *see* THIRTY YEARS' WAR) the viceroys had constantly to raise more troops and more money, and the measures to which they turned were resented as oppressive or contrary to the traditional privileges of Sicily. In May 1647, when the viceroy Pedro Fajardo, marqués de Los Vélez, had put a tax on grain and at the same time tried to keep the old price of loaves by reducing their weight, the people of Palermo rose in revolt and forced him to repeal the tax. Then, in July, the Palermitans, led by Giuseppe Alessio, rose again to demand the repeal of all taxes imposed since Charles V's death and the reservation of the viceroyalty and other public offices to Sicilians: the viceroy withdrew from Palermo and, fearing lest the Sicilian barons and the other towns might join the rebellion, began negotiations with Alessio. The latter, however, lost control over his riotous followers and was assassinated; Messina, always the envious rival of Palermo, remained loyal; the French took no advantage of the situation; and in September the viceroy and his Spaniards returned to the capital, where he died a few weeks later. His successor, faced with another revolt, had to concede a general amnesty. The events of the early summer had largely inspired the parallel revolt of Masaniello (*q.v.*) in Naples.

The revolt of Messina in 1674, during the reign of Charles II of Spain, was no less characteristic of Sicily under foreign rule than that of Palermo and was more serious because the French, at war with Spain again (*see* DUTCH WARS), were able to exploit it. The governor of Messina, Luis del Hoyo, wishing to break the stranglehold of the municipal oligarchy over the senate of Messina, tried to exploit popular discontent during a food shortage in order to introduce a popular element into the senate. The oligarchy stirred up its own popular reaction; Del Hoyo was replaced by Diego de Soria as governor; but conflict between the senate's and the governor's factions went on till, in Aug. 1674, Soria was besieged in his palace and forced to capitulate. The Messinese then appealed to Louis XIV of France, a French fleet arrived in September with supplies of food, and in April 1675 the duc de Vivonne (Louis Victor de Rochechouart) was sworn in as Louis XIV's viceroy of Sicily. Though Palermo declared itself for Spain against its traditional rival, the whole island might have fallen to the French if the Dutch had not sent a fleet, under the great M. A. de Ruyter, to support their Spanish ally. The naval war round the island was indecisive and Messina itself held out against the Spaniards till the French, making the peace of Nijmegen (1678), deserted the Sicilian cause. A viceregal amnesty to the rebels was revoked, and Messina's senate and privileges were abolished.

15. The Savoyard and Austrian Habsburg Interval.—Charles II's death (1700) was followed by the War of the Spanish Succession (*see* SPANISH SUCCESSION, WAR OF THE), during which Sicily's eventual fate was continually in discussion between the belligerent powers. The Austrians overran the kingdom of Naples (1707); and the Bourbon Philip V of Spain, under pressure from the English, ceded Sicily to Victor Amadeus II of Savoy at the peace of Utrecht (1713). The Franco-Austrian peace of Rastatt (1714) left the Austrians in possession of Naples and also gave Sardinia to them, but Spain was not a party to this peace.

The Spaniards, having seized Sardinia in 1717, invaded Sicily in July 1718. Victor Amadeus was unable to defend his kingdom without Austrian help. Austria, however, wanted to exchange Sardinia with him for Sicily; and this exchange had been included in the plan on which the Quadruple alliance of Great Britain, France, the United Provinces of the Netherlands and Austria (Aug. 1718) was formed for the settlement of the Austro-Spanish dispute.

The British admiral George Byng (later Viscount Torrington, destroyed the Spanish fleet off Cape Passero; the Austrians crossed the straits into Sicily; Victor Amadeus agreed to the plan for the exchange; and declarations of war against Spain were issued from Great Britain in Dec. 1718 and from France in Jan. 1719. By the treaty of The Hague (Feb. 1720) Spain accepted the terms of the alliance, and Sicily passed to Austria.

16. The Bourbons.—Extremely disliked in Sicily, the Austrian rule there came to an end during the War of the Polish Succession (*q.v.*), when the Spanish Bourbon infante Don Carlos, having first conquered Naples and the mainland for himself, was crowned king at Palermo in July 1735. Having initiated his great program of enlightened reform for his two Italian kingdoms (*see* NAPLES, KINGDOM OF), he abdicated Naples and Sicily to his third son, Ferdinand (III of Sicily), when he himself became king of Spain as Charles III in 1759. The antifeudal policy of the viceroy Domenico Caracciolo in the 1780s was resented by the Sicilian baronage, but Ferdinand was able to take refuge in Sicily when he was expelled from Naples by the French Revolutionary army in 1799. On his second expulsion from Naples, during the Napoleonic period, Ferdinand established himself in Sicily again (1806), to remain there, under British protection, for a far longer time. The British occupation, with Lord William Bentinck as ambassador in practical control of affairs from 1811, was chiefly important to Sicily for the constitution of 1812: the old parliament, ever jealous of its right to bargain with the crown, had been obstructing the war effort and so was superseded by a bicameral organ on British lines. Though this "English" constitution went some way to satisfying Sicilian particularism, it offended not only the king but also the more reactionary elements in Sicily insofar as it curtailed their privileges, notwithstanding its aristocratic bias.

The restoration of the Bourbons to Naples (1815) put an end to the constitution; and in 1816 the unitary kingdom of the Two Sicilies was proclaimed, subjecting Sicily to centralized government from Naples, with the king now styled Ferdinand I (*q.v.*). The Sicilians hated this; and, in 1820, Palermo rose in revolt for their constitution of 1812. The contemporary Neapolitan revolution, on the other hand, was for the democratic Spanish constitution of 1812, and troops from Naples suppressed the Sicilian autonomist movement before Naples in turn was put down for Ferdinand by the Austrians.

Ferdinand I was succeeded by Francis I (1825–30), the latter by Ferdinand II (*q.v.*; 1830–59). When revolution broke out in Sicily in Jan. 1848, the latter promised a constitution; but the Sicilians, acting again in disunion with the mainland, soon declared the deposition of the Bourbon dynasty and offered the crown to a prince of the house of Savoy. After the defeat of the Neapolitan revolution in 1849, Carlo Filangieri (*q.v.*) reduced Sicily to obedience again in April–May.

Francis II was the last Bourbon king of Sicily. Within a year of his accession, Giuseppe Garibaldi (*q.v.*) landed at Marsala with his "Thousand" on May 11, 1860 (*see* also ITALIAN INDEPENDENCE WARS OF; ITALY: *History*). A provisional government was formed at Palermo in June, a constitution was proclaimed in August; but after Garibaldi's conquest of Naples and his junction with the Sardinian-Piedmontese army, a Sicilian plebiscite in October decided by an overwhelming majority under universal suffrage for annexation to Sardinia. Messina, which held out for Francis, fell to the Piedmontese in March 1861. Sicily thus became part of the new kingdom of Italy.

17. The Italian Regione.—Despite the plebiscite, the house of Savoy found Sicily no more docile than earlier foreign dynasties had found it. Garibaldi's abortive *pronunciamiento* of 1862 was launched from Sicily and supported by the Sicilians, whom the royal government had to reduce by force. Brigandage and conspiracy continued into the 20th century, feeding on separatist tradition, on Catholic resentment at the government's treatment of the papacy before the Lateran treaty and on general discontent at the north's neglect of the backward south. Symptomatic of this state of affairs was the persistence of the Mafia (*q.v.*).

After World War II, during which Sicily had become a battleground (*see* WORLD WAR II: *The Sicilian Campaign*, May–August

1943), the Italian government gave more sympathetic attention to the island's problem. For the royal statute of autonomy (1946) and the republic's constitutional statute (1948) *see* below, *Regional Government*. (X.)

IV. POPULATION AND ADMINISTRATION

1. Population.—The population at the 1961 census was 4,631,382. The average density was 466.6 per sq.mi. compared with the national density of 429 per sq.mi. The chief characteristic of the distribution of population is the universal tendency to live in close-packed towns and villages, both in the coastal towns and in the agricultural towns of the interior which contain from 5,000 to 10,000 inhabitants or more. The birth rate rose from 21.5 in 1958 to 22.1 in 1961, while the death rate also rose from 8.6 in 1958 to 8.8 in 1961 so that the natural increase was 13.3 per 1,000. The rate of infant mortality dropped steadily from 55.4 per 1,000 live births in 1957 to 47.0 in 1961, but this was still high compared with northern Italy. Moreover the average figure for the whole island ignores the much higher figures reached in the mining province of Caltanissetta or in some communes of Agrigento province. Sicily's most serious problem is overpopulation. Before 1914 about 80,000 Sicilians emigrated overseas every year. Since 1951 there has been some emigration abroad, but the main movement of population has been to north Italy and within Sicily from the hill villages to the coastal towns. Industrial development associated with the oil production of the Ragusa-Gela district is beginning to alleviate Sicily's unemployment problem (see *The Economy*, below).

2. Regional Government.—Sicily is one of the five regions of Italy which obtained a special form of local autonomy under the constitution of 1948 (*see* ITALY). Sicilian regional status was conferred by an Italian constitutional law (1948). The regional capital is Palermo and there are nine provinces (Agrigento, Caltanissetta, Catania, Enna, Messina, Palermo, Ragusa, Syracuse [Siracusa] and Trapani). The background of regional government in Sicily is totally different from that of the other regions enjoying local autonomy. The history of Sicily, occupied by many invaders and for long periods separated politically from the mainland, had produced a people differing greatly in character and habits from the inhabitants of the mainland. Sicily accepted incorporation in Italy in 1860, but the political institutions of Piedmont were not well suited to it, and the centralized control imposed by the government in Rome, afraid of any threat to Italy's recently won unity, checked the possibility of local autonomy. There was no political separatist movement before 1940, but there was a general feeling of discontent and widespread belief that the interests of Sicily were sacrificed to those of the industrial north.

In 1943 it gradually became clear that very few Sicilians wanted separation from Italy but that a large number wanted a considerable measure of local autonomy. The Italian government installed a high commissioner with plenary executive powers in Jan. 1944; and a royal decree law of May 15, 1946, granted Sicily a statute of autonomy which was converted unchanged into the constitutional statute of Feb. 26, 1948.

The statute gave Sicily a very considerable degree of self-government. The regional assembly (*consiglio regionale*; the local parliament) can be dissolved only for persistent violation of the statute and then only after a debate in the Italian parliament. The assembly's legislative powers are more extensive than those of any other region. Elementary education is in its hands, and legislation on higher education (including university education) is limited only by the need to conform to the general principles of national education. Without prejudice to the national parliament's plans for agrarian and industrial reform the regional assembly has exclusive power to legislate on all questions concerning agriculture, land reclamation, industry and commerce.

The president of the region is elected by the assembly from among its members. He not only represents the region, promulgates regional laws and, together with the *giunta* (the executive committee of the assembly), constitutes the government, but also has the right to attend meetings of the Italian council of ministers with the rank of minister and to speak when Sicilian questions are under discussion (though he has not the right to vote). The president and *giunta* are invested by the statute with the supremely important executive function of maintaining public order by means of the national police force, although at their request the national government can act jointly with them. The president also represents the national government in Sicily.

The financial provisions of the statute are peculiar to Sicily. The island is expected to provide for its own expenditure by raising its own taxes, but the Italian state has agreed to hand over to the region a share of the taxation raised from firms which have factories or offices in Sicily though their central offices are not in the island. The state has also to pay over a lump sum annually for public works in Sicily.

3. Social Conditions.—Sicily is the richest of the southern regions in natural resources, but the standard of living of the majority of Sicilians is as low as that of south Italy. In 1960, 39.4% of the working population was engaged in agriculture compared with Italy's average of 30.8%. The contrast between the highly productive areas round Palermo and Catania, on the lower slopes of Etna and along parts of the coast and those in the mountainous interior still given over to extensive arable farming remains great. Life in many of the agricultural towns of the interior is primitive. Many such towns are without adequate sanitation, some still without a water supply, and serious overcrowding is common. Disease is consequently rampant. There is serious agricultural unemployment and above all underemployment. In the southeast corner of Sicily there has been a great change since 1957. Industry is growing rapidly associated with the development of oil. Since 1960 the number of industrial workers has increased steadily.

Education follows the general lines of Italian national education, although the regional government has complete control of primary education. The rate of illiteracy is high, double that of Italy, and there is a great shortage of schools. There are three universities, at Palermo, Messina and Catania, with a total of about 23,000 students. Provision is slowly beginning to be made for technical education.

Social services as a whole are organized like those on the mainland but the standard is poor. Housing conditions in the towns as well as the villages are not good and there is a great shortage of medical services. The hand of the Mafia (*q.v.*) undoubtedly lies heavily on the whole social life of Sicily and has put great obstacles in the way of social improvement. In 1962 the Italian government appointed a parliamentary commission to enquire into the causes of the Mafia and to propose measures necessary for its repression. (M. M. C.)

V. THE ECONOMY

1. Agriculture.—In 1936 more than half the employed population of Sicily was engaged in agriculture. World War II did not materially alter the economic structure of the island and in 1951 the proportion was 51%. The outstanding feature of Sicilian land use is the very high proportion of the total area given over to agriculture and forest, more than 95%.

Sicilian agriculture is dominated by the lack of water, which limits production and restricts the use of modern technical methods. Both intensive and extensive methods of cultivation exist. On Aug. 10, 1950, a law was passed by the Italian government to initiate a fifteen-year economic development plan (1950–65) for the southern regions including Sicily. Under the direction of the *Cassa per il Mezzogiorno* public works such as land reclamation, flood and erosion control projects, construction of aqueducts and sewers, provincial roads and railways were being undertaken. Among the many completed schemes are the irrigation of the Gela district (including the Disueri dam) and of the Catania and Lentini plains, and the reafforestation, flood and erosion control projects of the upper Simeto and Salso basins, where the Pozzillo dam has been constructed to irrigate the Catania plain. Areas where irrigation has long been part of the agricultural system are on the slopes of Etna and of the Iblei mountains, around Marsala and in the Conca d'oro behind Palermo. Citrus fruits and vegetables grow in abundance and provide the main source of the island's

agricultural exports. In these fertile areas small holdings are important and the majority of the farms are less than seven acres. Extensive farming prevails all over the interior where the practically treeless land produces the wheat for which Sicily has been famous for more than 2,000 years.

The characteristic estates of the interior were the *latifondi*, large, extensively cultivated estates frequently owned by absentee landlords and run on capitalist lines by middlemen who employed a few workers engaged by the year (*salariati*) and large numbers of badly paid day labourers. Before 1939 farms of more than 125 ac., which constituted less than 1% of the total number of farms in Sicily, occupied 36% of the land. Large areas were also sublet in fragmentary holdings to peasants who farmed the land extensively and thus created what is known as the *latifondo contadino* (the peasant's *latifondo*).

Subject to general conformity with the Italian parliament's plans for land reform, the regional government of Sicily has exclusive power to legislate on all agrarian questions. To change the system of extensive *latifondo* farming, however, was a difficult proposition. The shortage of water throughout the interior meant that any plan for abolishing the great estates and for establishing peasant proprietors would be meaningless unless it made provision for a regular and sufficient water supply, which alone would make it possible to grow other crops than wheat; and supplies of water and better local roads were also required if the peasants were to be persuaded to live in small villages near their fields. Yet the Sicilian regional government made a beginning. On Dec. 27, 1950, a law was issued on the expropriation of land applicable to the whole island: 69,500 ac. were listed for expropriation (this amount was expected to rise to 250,000 ac.). Intensively cultivated land was exempt. The work of expropriation and redevelopment was entrusted to the Sicilian Land Reform agency in Palermo under the general supervision of the Italian ministry of agriculture.

Sicily's most important crop is wheat and in 1961 nearly 645,000 ha. of the arable land were sown to wheat; production amounted to 700,640 metric tons, more than 8% of the total Italian wheat production. The yield, however, was low: Sicily produced only 10.9 quintals per hectare, as compared with the average of 19.6 for the whole of Italy and 35.0 for Lombardy. The second most important crop consists of citrus fruits, particularly lemons, of which Sicily produced 443,830 metric tons in 1961, about 90% of Italy's total lemon crop. The island also produces large quantities of fresh vegetables, particularly tomatoes, artichokes, peas and beans, and their early season makes them a profitable export crop. Much wine is produced, mostly for local consumption; Marsala, however, is a valuable export wine.

Stockraising.—The estimated number of cattle in Sicily rose from 168,000 in 1930 to 277,000 in 1961; although the latter figure compared favourably with those for southern Italy it was admittedly low. The supply of fodder is poor, there are few permanent meadows, and much of the pasture is suitable only for sheep and goats, which numbered fewer than 900,000. Donkeys and mules are used everywhere by peasants, and with their bells and packs are a characteristic feature of Sicilian life.

2. Fisheries.—In 1959, 24% of the Italian fishing fleet was registered in Sicily, and fishing was an important source of employment. The most valuable fish caught is tunny (tuna); some is eaten fresh in Sicily but most is canned for export. The total Sicilian catch amounted to a considerable proportion of the national catch and the tunny catch exceeded three-quarters.

3. Industry.—The small canning industry of fish, fruit and vegetables was greatly expanded after 1945. The sulfur deposits of the central-southern part of Sicily are mined where the sulfur content reaches 16%–20%. Output is declining because of competition from the U.S., high production costs and the need to modernize the mines. Oil discovered around Ragusa, Gela and Fontanarossa is rapidly developing into one of the largest European oil fields. In the early 1960s production amounted to about 2,000,000 metric tons. Associated industries have developed and industrial growth generally has been greatly stimulated by financial aid supplied by the *Cassa per il Mezzogiorno*. A plant for the fabrication of polythene and ethylic alcohol is in operation at Ragusa. Oil refineries are at Ragusa, Gela and Augusta. Chemical and pharmaceutical plants are at Catania and Gela, and large fertilizer plants at Porto Empedocle and Licata. The cement industry is growing in importance and new factories have been constructed at Palermo and Augusta.

4. Communications.—Sicily's three chief ports are Palermo, Messina and Catania. A regular shipping service connects Palermo with Naples, and Messina is linked to the mainland by the train-ferry across the straits. The three chief ports are connected by three main railway lines, all single-track: one along the north coast from Palermo to Messina; one along the east coast from Messina to Catania and Syracuse; and one running inland from Catania to Palermo via Enna. The remarkable narrow-gauge circum-Etna railway, which climbs to 3,196 ft., is not a mere tourist line but carries heavy loads of agricultural produce. There are other secondary lines, but these are subject to severe gradients and curves.

Main roads between important towns are good, but there is a dearth of good secondary roads, and some small hill towns or villages can be reached only by steep mule tracks. The main airports are near Palermo and Catania.

SICKERT, WALTER RICHARD (1860–1942), influential British painter, was born at Munich on May 31, 1860, the son of Oswald Adalbert Sickert, a Danish-born German draftsman who settled in England in 1868. After several years on the stage, Sickert went in 1881 to the Slade school of art in London; he retained, however, something of the make-up of a late Victorian actor-manager. He studied under Alphonse Legros but through his father knew the works of Thomas Couture and Gustave Courbet. In 1882 he became a pupil of Whistler and in 1883 met Degas in Paris; these artists much influenced his work and personality. His first pictures of London music-hall interiors appeared in 1886, and, at the New English Art club, founded in that year, Sickert exhibited until 1917.

Like Whistler, Sickert used tonal methods to gain his effects, and his colours up to about 1904 are sombre. To Degas he was indebted for the ability to establish a situation merely by the attitudes of the figures—an innovation in England, where narrative painting was then governed by literary principles. Sickert coupled this with a refreshing vein of satire.

Between 1885 and 1905 Sickert spent most summers at Dieppe and worked in Venice. Returning to London in 1905 he became the focus of a group of painters which included Lucien Pissarro, Spencer Gore, Harold Gilman and Augustus John. Through Gore's and Pissarro's influence, Sickert's work began to show the influence of Neoimpressionism, though he was unmoved by the more advanced French styles then beginning to be known in London. He was a founder of the Camden Town and London groups (1911 and 1913) and was made a royal academician in 1934, resigning in 1935.

Sickert painted at Brighton and Bath in the 1920s and 1930s and wrote occasional criticism, supporting the principles of drawing observed by Degas. Such principles, and Sickert's own style, have been vital to English art and teaching. He died at Bath Somerset, on Jan. 22, 1942. His grandfather, Johann Jürgen Sickert (1803–64), and his brother Bernhard Sickert (1862–1932) were also painters.

SICKINGEN, FRANZ VON (1481–1523), an enigmatic figure of the early years of the Reformation in Germany, was born at Ebernburg near Worms on March 2, 1481. A member of the *Reichsritterschaft,* or class of free knights, he became a sort of German *condottiere* and acquired considerable wealth and estates in the Rhineland as the result of immensely profitable campaigns against private individuals and against cities such as Worms (1513) and Metz (1518). In 1518 he led the army of the Swabian league against Ulrich I of Württemberg. After the death of the Holy Roman emperor Maximilian I in 1519, Sickingen, while accepting bribes from Francis I of France, used his influence to support the election of Charles V as emperor. The presence of his troops around Frankfurt, where the election was held, certainly helped Charles. For this service he was made imperial chamberlain and councilor.

Sickingen supported both the nationalist schemes of Ulrich von Hutten and the religious reforms of Martin Luther. He protected Johann Reuchlin against the Dominicans in 1519 and helped guarantee Luther's safe conduct to Worms in 1521. He harboured many humanists and reformers in his castles, which became, in Hutten's words, "a refuge for righteousness." When the knights' war broke out in 1522, as a rising of his class in defense of its ancient status, Sickingen, who the previous year had led an abortive and inglorious expedition to France, placed himself at the head of it. He declared war against his old enemy Richard of Greiffenclau, archbishop of Trier and a friend of the French. He sadly underestimated the opposition. Trier remained loyal to the archbishop, and princes such as Philip of Hesse rallied to his support; Sickingen was repulsed, his support fell off, and he was declared an outlaw. He was forced on the defensive; the Swabian league declared against him; his castles fell one by one; and on May 6, 1523, he capitulated in his last stronghold at Landstuhl. He died the next day and was buried there. In 1889 a splendid monument was raised at Ebernburg to his memory and to that of Hutten.

Sickingen's life in the end was a tragic waste in spite of all his outstanding qualities. He championed a dying cause. The class of knights was being overtaken by the growing influence both of the towns and of the princes and was an anachronism in the new modern world that was evolving, the main occupation of its members being private warfare. Had they been properly organized and led, the knights might well have harnessed the wave of nationalist feeling in Germany, and particularly in the Rhineland, to productive ends. Sickingen, for all his power and influence, was no more able to do this than was Hutten. On the one hand a champion of the poorer classes, a sincere Lutheran and genuine patriot, he was on the other hand a self-interested opportunist who probably aimed at high office. In the end he accomplished little.

SICULI (English SICELS; Greek SIKELOI), an ancient Sicilian tribe. In historical times they occupied the eastern part of the island, to which they gave their name. There was an ancient tradition that the Siculi once lived in central Italy east and even north of Rome, but were driven out and finally crossed to Sicily, leaving remnants behind; *e.g.,* at Locri (*q.v.*). They were distinct from the Sicani (*q.v.*) in the west of the island. They are hard to identify archaeologically ("Siculan," as used in archaeology, being purely a conventional term; *see* SICILY: *Archaeology*); some words of their Indo-European language are known.

The Siculi lived in independent towns; they were easily dis-

placed by the Greek colonies (*see* SICILY: *History*) and did not react *en masse* till the 450s B.C. under Ducetius (*q.v.*). The most important Sicel gods were the Palici, protectors of agriculture and sailors, who had a lake and temple near the Symaethus (Simeto) River; Adranus, sometimes said to be the father of the Palici, a god akin to Hephaestus, whose temple and everlasting fire were guarded by hounds; and the goddess Hybla or Hyblaea, whose sanctuary was at Hybla Geleatis. The chief Sicel towns were Agyrium (modern Agira), Centuripa or Centuripae (Centuripe), Henna (Enna), and three towns called Hybla (*q.v.*).

SICYON (or SECYON, the local form; modern Greek SIKION), an ancient Greek city in the northern Peloponnese, about 11 mi. (18 km.) NW of Corinth and 2½ mi. (4 km.) SW of modern Sikionia. Its site is a low triangular plateau about 2 mi. (3 km.) from the Corinthian Gulf, at the confluence of the Asopus (Asopos) and Helisson (Elisson) rivers. Between city and port lay a fertile plain.

Its original name was said to have been Aegialeia ("beach town"), and it was inhabited in Mycenaean times. In the *Iliad* it is mentioned as subject to Agamemnon and previously ruled by Adrastus, king of Argos, who was still honoured as a hero at Sicyon in historical times. After the Dorian invasion it had the three Dorian tribes (*see* DORIANS) with a non-Dorian tribe called Aigialeis and a class of serfs, the "club-bearers" (*korunephoroi*) or "smock-wearers" (*katonakophoroi*). For several centuries Sicyon was subject to Argos. Independence was established in the 7th century by non-Dorian tyrants, called Orthagorids after their founder, Orthagoras; their mild rule lasted longer than any other Greek tyranny (*c.* 655–*c.* 555 B.C.). The most famous of the Orthagorid tyrants, Cleisthenes (*q.v.*), had connections with many commercial centres of Greece and south Italy and held an international competition before finally marrying his daughter to Megacles of Athens. Besides reforming the city's constitution and replacing Dorian cults with that of Dionysus, he took a chief part in the Sacred War (*c.* 590) in the interest of Delphi. Cleisthenes' successor, Aeschines, was expelled by the Spartans, but his institutions survived till the end of the 6th century, when Dorian supremacy was re-established and the city joined the Peloponnesian League. Henceforth Sicyonian policy was usually determined by Sparta or Corinth, though Argos retained some ascendancy (perhaps religious) in the 490s.

Sicyon supplied ships and 3,000 infantry to fight the Persians in 480–479. Its 6th-century bronze sculptors included Canachus (*q.v.*). In the 5th century it suffered like Corinth from the commercial rivalry of Athens and was repeatedly harassed by Athenian ships. In the Peloponnesian War (431–404) Sicyon followed Sparta and Corinth, and in the Corinthian War (394–386) it sided with Sparta. In 369 or 368 it was captured and garrisoned by the Thebans. Soon after this Euphron became tyrant with popular support, but his position was insecure and exiled Sicyonian oligarchs murdered him on an embassy to Thebes (*c.* 365). The oligarchy was restored, but new tyrants soon arose with the help of Philip II of Macedonia. During this period Sicyon reached its zenith as a centre of art: Apelles studied painting there, and Sicyonian sculpture culminated in Lysippus and his pupils. After participating in the Lamian War under a second Euphron (killed 322), and in the struggles between the successors of Alexander the Great, Sicyon was captured (303) by Demetrius Poliorcetes, who transplanted the inhabitants to the acropolis and renamed the site Demetrias. In the 3rd century it passed from tyrant to tyrant, until in 251 it was liberated by Aratus (*q.v.*) and enrolled in the Achaean League (*q.v.*). The destruction of Corinth (146) brought Sicyon additional territory and presidency over the Isthmian Games; but in 58 B.C. the Sicyonians had to sell their works of art to meet the city's debts. Under the Roman empire it was quite obscured by the restored Corinth and Patrae; Pausanias (*c.* A.D. 150) found it almost deserted after an earthquake. In Byzantine times it had a bishop, and there was an Early Christian basilica at Sikionia. Sicyon's later name, "Hellas," may mean that it was a refuge for Greeks fleeing the Slav invasions.

Ancient fortifications are still visible, and remains of a theatre, a gymnasium, a stadium, and other buildings, including a Roman bath, now the museum.

See C. H. Skalet, *Ancient Sicyon* (1928; with bibliography); A. Andrewes, *The Greek Tyrants,* ch. 5 (1956).

SIDAMA, derived from the tribal name Sidamo, is a term applied to Hamites (Cushites) of southwestern Ethiopia (*q.v.*), consisting of (i) the Sidamo, Darasa, Hadya, Kambatta, Tambaro, and Alaba, in the area between the Omo River and lakes Zeway, Shala, and Awasa; (ii) the Wolamo, Kucha, Gamo, Gofa, Konta, Kullo, Zala, and Kuera or Koyra, between the Omo and Lake Abaya (Margherita); (iii) the Chara, Basketo, Zaysse, Doko, and other minor tribes southwest of group ii. Linguistically, groups ii and iii are known as Ometo, "people of the Omo." Population figures for this area were very uncertain in the 1960s, the total being estimated at somewhere between 250,000 and 1,500,000. (*See* also GURAGE; JANJERO.)

All groups are agricultural, though many of them keep cattle. The principal food is ensete (Abyssinian banana); chicken or fish is not eaten. Until they were conquered late in the 19th century by the Ethiopians, all the Sidama tribes were small independent kingdoms. There is an age-grade system (*gada; see* AGE SET) derived from the Galla (*q.v.*) among the Sidamo, and in many tribes there are submerged classes; *e.g.,* smiths, weavers, potters, tanners. There is a widespread cult of a sky-god (called Wa'a in group i, Tosa or Tsosa in group ii) associated with a cult of nonancestral spirits. Some of the peoples are Monophysite Christians (*see* MONOPHYSITES) or Muslims, but paganism seems to predominate. *See* also AFRICA: *Ethnography* (*Anthropology*): *Northeast Africa;* CUSHITIC PEOPLES.

SIDDONS, SARAH (née KEMBLE) (1755–1831), one of the greatest English tragic actresses, was born at the Shoulder of Mutton Inn, Brecon, Wales, on July 5, 1755, the eldest of the 12 children born to Roger Kemble and his wife, Sarah (née Ward; *see* also KEMBLE). As a child she acted with her father's strolling company, gaining what education she could as they traveled about, and soon proved an excellent actress. At the age of 18 she married William Siddons, a handsome but somewhat insipid actor who had been a member of her father's company. Having broken away from the family and joined another company, Sarah made her first success at Cheltenham. When David Garrick sent a representative to see her, she was playing Rosalind in *As You Like It* in a barn in Worcestershire and was also expecting a baby, but Garrick nevertheless offered her an engagement. This she could not accept until after the child was born. When she appeared at Drury Lane, London, with Garrick in 1775 she was a failure. Consequently she went back on tour in the country, and there she earned great favour, becoming the tragedy queen of the English stage and drawing vast crowds everywhere she appeared.

In 1782, at the request of Richard Brinsley Sheridan (who had succeeded Garrick), she consented, although with reluctance, to appear at Drury Lane again. There was no mistake this time: she chose the part of Isabella in *Isabella, or The Fatal Marriage,* and her success was phenomenal. From that time onward she reigned as queen at Drury Lane until, in 1803, she and her brother John Philip Kemble went to Covent Garden. In 1783 she was appointed to teach elocution to the royal children. She retired from the regular stage on June 29, 1812, with a farewell performance that was memorable: the audience would not allow the play, *Macbeth,* to proceed beyond the sleepwalking scene, in which she gave an exhibition of perfection, for it was as Lady Macbeth that Mrs. Siddons excelled.

She played all the great roles of tragedy, wisely leaving comedy alone (she nearly failed as Rosalind in *As You Like It*), but as a tragic actress she was one of the greatest the English stage—and possibly that of the world—had seen. Her power over her audi-

ences was complete; she held them under her sway. Lady Macbeth, Isabella, Belvidera in *Venice Preserv'd*, Jane Shore, Katharine in *Henry VIII*, Constance in *King John*, Zara in *The Mourning Bride*, and Volumnia in *Coriolanus* were her great parts. Just over middle height, she had a superb figure, classical features, large and eloquent eyes, a rich, resonant voice, and perfect diction. Her success was due to her complete concentration upon the character she played: she identified herself with it and seemed possessed by it, oblivious of all else around her, and when she uttered a shriek she seemed able to pierce the very soul of her audience. The mother of five children, she died in London on June 8, 1831.

See Yvonne Ffrench, *Mrs. Siddons: Tragic Actress* (1936).

(W. J. M.-P.)

SIDE (modern SELIMIYE, Turkey), an ancient city on the Pamphylian (central southern) coast of Asia Minor about 5 mi. (8 km.) W of the mouth of the Melas (Manavgat) River. It was founded by Greeks from Cyme in Aeolis (though a peculiar non-Greek language was also spoken there). It was the most important place in Pamphylia, having a good harbour of two small moles and two artificial harbours for larger vessels at the apex of its triangular site. Alexander the Great occupied it (333 B.C.), and there the Rhodian fleet defeated that of the Seleucid king Antiochus III (190 B.C.). In the 1st century B.C. the Cilician pirates made it their chief slave market. The great ruins cover a large promontory, fenced from the mainland by a ditch and wall, which survives with Byzantine modifications. Within this is a maze of structures out of which rises the colossal ruin of the theatre, built upon arches; it is the finest in Asia Minor.

See A. M. Mansel, *Die Ruinen von Side* (1963).

SIDERITE (CHALYBITE), a mineral consisting principally of ferrous carbonate, but frequently containing substantial amounts of manganese and magnesium and lesser amounts of calcium substituted for iron. Also known as spathic iron ore, its principal use is as a source of iron for the manufacture of iron and steel, especially in Great Britain and Austria (*see* IRON: *Compounds of Iron;* IRON AND STEEL INDUSTRY: *Iron Ore*). Ferrous carbonate, not necessarily produced directly from siderite, is used in the treatment of anemia and in the preparation of other iron compounds. The composition is expressed by $FeCO_3$. The hardness is 3.5–4, the specific gravity is 3.96 (for pure $FeCO_3$) and the colour is usually a shade of brown because of partial oxidation.

Siderite is found in small amounts in cavities in basaltic igneous rocks and as a subordinate gangue mineral in hydrothermal metallic veins and in some pegmatites. It is widely distributed as a fine-grained concretion (*q.v.*) and in thin beds associated with shales and coal seams. Organic matter preserved in the latter rocks has been taken to indicate that they were formed in reducing environments, and indeed siderite has been observed in some swamps forming under such conditions. Siderite is also found in sedimentary rocks of Jurassic age in England and western Europe admixed with varying amounts of calcitic shells and oölites of the iron silicate chamoisite. It is a constituent of the banded iron ores of the Lake Superior district. (D. L. G.)

SIDEROSTAT, an instrument which, like the coelostat and heliostat (*qq.v.*) reflects a portion of the sky in a fixed direction notwithstanding the diurnal motion of the heavens. The name is applied especially to the polar siderostat, a form of telescope in which the observer looks down the polar axis onto a mirror; by adjusting the mirror he can bring any part of the sky into the field of view without changing his own position.

SIDGWICK, HENRY (1838–1900), English philosopher, best known for his theories concerning ethics, was born at Skipton in Yorkshire on May 31, 1838. He was educated at Rugby and at Trinity college, Cambridge. In 1859 he was elected fellow of Trinity and then lecturer in classics. In 1869 he exchanged this lectureship for one in moral philosophy, but resigned his fellowship on religious grounds.

He was appointed praelector in 1875 and elected to an honorary fellowship in 1881. In 1883 he was appointed Knightsbridge professor of moral philosophy; and in 1885, the religious test having been removed, Trinity again elected him to a fellowship on the foundation. He died on Aug. 29, 1900.

Sidgwick took an active part in university business and especially in promoting the higher education of women through the foundation of Newnham college. He had married in 1876 Eleanor Mildred Balfour (sister of A. J. Balfour) who succeeded Miss A. J. Clough as principal of Newnham in 1892. He was active in social and philanthropic work and deeply interested in psychical phenomena, being a founder and first president of the Society for Psychical Research. But his energies were mainly directed to the study of religion and philosophy.

Sidgwick's major work was *Methods of Ethics* (London, Cambridge, 1874; 6th ed., London, 1901; reissue of 7th ed., 1930). His three "methods" are egoism, utilitarianism and intuitionism. Egoism is the theory that justifies an action by its contribution to the greatest happiness of the agent, utilitarianism by its contribution to the greatest happiness of all those affected by it. Sidgwick uses "intuitionism" to designate all theories which recognize ultimate ends other than happiness or ultimate rules other than the rule that the maximum happiness ought to be promoted. In support of intuitionism, Sidgwick admits that ordinary men regard many rules as binding on them independently of the happiness produced and also that they often regard ends other than happiness (ends such as knowledge, beauty and virtue) as intrinsically desirable. But he argues that the rules of common sense are vague and indefinite; they allow exceptions and conflict with each other. Thus they cannot be regarded as providing an adequate rational basis for conduct. Most of them can, however, be justified as tending to promote general happiness, and the principle of utility can always be invoked to render their application more precise, to explain their exceptions and to resolve their conflicts.

While rejecting psychological hedonism, Sidgwick points out that any action can be rationally justified by demonstrating its contribution to the happiness of the agent. This egoistic principle, indeed, if taken as the sole guide to life, seems repellent to the moral sentiment; and when a man's private good conflicts with the general good most men agree that the former should yield. Yet even such lofty moralists as Joseph Butler and Samuel Clarke are found suggesting that enlightened self-love is the supreme principle of rational conduct. Utilitarianism appears to Sidgwick to be the only principle capable of giving rational unity to moral consciousness. But he finds it difficult to reconcile its moral claims with the rational supremacy of self-love. There is no empirical evidence that a man's achievement of the greatest general happiness will in fact entail his own greatest happiness. . Some thinkers, such as Plato and Kant, relied here on a belief in the divine ordering of the world to guarantee this coincidence. Sidgwick concludes that only such a belief (whether based on theology or imported as an *ad hoc* postulate) will serve to bring unity to the world of rational conduct.

Sidgwick's claim to distinction does not rest on the originality or conclusiveness of the doctrines summarized above. His work is marked by caution and thoroughness, a masterly exposure of confusions and ambiguities, an acute and balanced presentation of complex argument and an open-minded candour and honesty.

Sidgwick's chief works are *Principles of Political Economy* (1883; 3rd ed., 1901); *The Scope and Method of Economic Science* (1885); *Outlines of the History of Ethics* (1886; 6th ed., 1931), enlarged from his article "Ethics" in the *Encyclopædia Britannica*, 9th ed., vol. viii (1879); *Elements of Politics* (1891; 2nd ed., 1897; reissue of 4th ed., 1929). The following were published posthumously: *Philosophy: Its Scope and Relations* (1902); *Lectures on the Ethics of T. H. Green, Mr. Herbert Spencer and J. Martineau* (1902); *The Development of European Polity* (1903); *Miscellaneous Essays and Addresses* (1904); *Lectures on the Philosophy of Kant* (1905). (J. D. M.)

SIDGWICK, NEVIL VINCENT (1873–1952), English chemist whose conception and elaboration of electronic bonding was a valuable interpretation of chemical union, was born on May 8, 1873, at Oxford. Sidgwick received his M.A. at Oxford university and his Ph.D. at Tübingen. He became fellow and tutor at Lincoln college, Oxford, in 1901, reader in chemistry at Oxford in 1926 and professor in 1935, a position which he held until 1945. His books are: *Organic Chemistry of Nitrogen* (1910), *Electronic Theory of Valency* (1927), *The Covalent Link in Chemistry* (1933) and *The*

Chemical Elements (1950) in two monumental volumes. Sidgwick was Baker lecturer at Cornell (N.Y.) in 1931, vice-president of the Royal society in 1935–37, president of the Faraday society in 1932–34 and president of the Chemical society in 1935–37. He received the Royal medal of the Royal society in 1937 and the Longstaff medal in 1945. He died March 15, 1952, at Oxford.
(V. Bw.)

SIDHI, a town in Madhya Pradesh, India, and the headquarters of the district of the same name. Pop. (1961) 5,021. It is situated on the northern outcrops of the Vindhya Mountains at a height of 706 ft. (215 m.) above sea level overlooking the Son River. Sidhi has no railway communications; one metaled road, 46 mi. (74 km.) long, connects it with Rewa (*q.v.*) to the northwest.

Sidhi District is the most northeasterly district of Madhya Pradesh. It covers an area of 4,060 sq.mi. (10,515 sq.km.) and has a population (1961) of 580,129. The southern part of the district is hilly and undulating. The northern part is flat country and is drained by the Son and its tributary toward the northeast. The climate is hot and moist, the average annual rainfall being 45 in. (1,143 mm.). The soil is mostly laterite and crops include rice, wheat, barley, and gram. Nearly nine-tenths of the population is engaged in agriculture. The hilly tracts of the south are inhabited by tribal peoples. (M. N. K.)

SIDI BEL ABBÈS, the chief town of an *arrondissement* in the Oran (Ouahran) *département*, Algeria, lies at an altitude of 1,552 ft. on the Mékerra River, 48 mi. (77 km.) S of Oran by rail. Pop. (1960) 105,357 (commune), about 65,000 Muslim. The town derives its name from the tomb of the marabout (saint) Sidi Bel Abbès, and was founded by French troops in 1843, becoming a *commune* in 1856. Sidi Bel Abbès was the depot and recruiting station of the Foreign Legion. The Legion's barracks contained the Legion Museum, comprising the Salle d'Honneur, with the colours of the Legion's regiments and their principal trophies, and the Musée du Souvenir. The town was evacuated by the Legion and all French troops after Algerian independence. It was formerly surrounded by walls and bastions, with four gates, but these were demolished and replaced by boulevards and squares, beyond which are the spreading suburbs. Other buildings include that of Les Coopératives Agricoles (Union of Farmers), the town hall, a mosque, churches, and a theatre; there are a *lycée* and other schools. The town is on the Oran-Tlemcen-Oujda railway and an airport is 3 mi. distant. The surrounding area, once swampy, now produces cereals (mainly wheat and barley) and vines.
(A. Am.)

SIDMOUTH, HENRY ADDINGTON, 1st Viscount (1757–1844), English statesman, prime minister from 1801 to 1804, and home secretary from 1812 to 1822, was the son of Anthony Addington, a physician, and was born in London on May 30, 1757. Educated at Winchester College and at Brasenose College, Oxford, he became a member of Parliament for Devizes, in Wiltshire, in 1784. He was a personal friend and strong supporter of William Pitt, and in 1789, with Pitt's help, became speaker of the House of Commons. Rejecting offers of a position in the Cabinet, he held this post until 1801. In that year, after Pitt had quarreled with George III on the question of Catholic emancipation, the more pliable and very Protestant Addington became prime minister, a position he held until April 1804. He was responsible for the Treaty of Amiens in March 1802, a settlement which at first increased his popularity in the country, but when it proved only temporary Addington's fortunes became less favourable. War had been renewed in May 1803, and it became increasingly clear that Addington lacked the necessary gifts of a war leader, and Pitt, who began openly to oppose the government, took his place.

Addington's continued importance in politics depended not on his personality and his abilities so much as on a little group of about 50 followers in the House of Commons. In January 1805 Addington and his group supported Pitt, and Addington himself, who was now created Viscount Sidmouth, reentered the Cabinet as lord president of the council. In July 1805 he broke away again but entered the opposition ministry of Charles James Fox and George Grenville in February 1806 as lord privy seal. Remaining true to his Protestant, Church of England allegiance, he left the new ministry in 1807 when the government proposed to throw open commissions in the Army and Navy to Roman Catholics and dissenters. As a spokesman of the Church of England party he attempted in 1811 to bring in a private bill requiring all dissenting ministers to be licensed, and restraining unlicensed preachers. The bill was unsuccessful, but a year later he returned to the Cabinet as lord president of the council under Spencer Perceval. After Perceval's assassination (May 1812) and the formation of the earl of Liverpool's ministry, Sidmouth became home secretary in June.

He had to deal with a discontented population disposed to demonstration and riot. The first year of his office was one of high prices, commercial difficulties, and large-scale unemployment; to control the situation, in face of demonstrations both by manufacturers and by Luddites, he increased the power of the magistrates. After 1815 he carried this policy of firmness much further. In 1817, for instance, he issued a circular to the lords lieutenant declaring that magistrates might apprehend and hold to bail persons accused on oath of seditious libels, and was supported by Parliament even after a publisher, William Hone, had been acquitted by a jury on charges which followed Sidmouth's instructions. He was mainly responsible for the later policy embodied in the Six Acts of 1819, which, among other provisions, limited the rights of public meeting and the circulation of political literature. His instructions to magistrates and his use of police spies made him detestable to all Radicals and Liberals. Exhausted by his efforts, he resigned office in January 1822, but, with the strong support of George IV, he remained in the Cabinet until November 1824, when he resigned because of his disapproval of the recognition of the South American republics. Thereafter he took little part in public affairs, although he remained a strong supporter of church and king, in 1829 speaking against Catholic emancipation and in 1832 voting against the Reform Bill. He died at the White Lodge, Richmond Park, on Feb. 15, 1844. Sidmouth was a statesman of limited imagination and no outstanding ability, but his character and integrity could not be questioned: his inability to assess the forces of change in English politics prevented him from leaving any permanent mark on English history.

Bibliography.—G. Pellew, *The Life and Correspondence of . . . Viscount Sidmouth*, 3 vol. (1847); Sir G. C. Lewis, *Essays on the Administrations of Great Britain from 1783 to 1830* (1864); Sir S. Walpole, *History of England from . . . 1815*, 5 vol. (1878–86); W. R. Brock, *Lord Liverpool and Liberal Toryism, 1820–1827* (1941). (A. Bri.)

SIDMOUTH, a seaside and resort town and urban district in the Honiton parliamentary division of Devon, Eng., 15 mi. (24 km.) ESE of Exeter by road. Pop. (1961) 10,890. Area 17.9 sq.mi. (46.4 sq.km.). It lies in the valley formed by the Sid in the red sandstone cliffs edging the western end of Lyme bay. Traces of a Bronze Age camp have been found on High Peak; on Salcombe Hill is the Norman Lockyer Observatory, now belonging to the University of Exeter. The beach is pebbly, with sand at low tide, and most of the houses were built during the Regency period when Sidmouth became popular. Agriculture is a main industry.

SIDNEY (Sydney), **ALGERNON** (1622–1683), English politician executed for treason, exercised a lasting posthumous influence in Great Britain and America as a champion of constitutional liberties. The second surviving son of Robert, 2nd earl of Leicester, Sidney was born at Penshurst Place, Kent. In October 1641 he went to Ireland with his brother Philip, and helped to suppress the rebellion there. The brothers returned to England in August 1643 and, suspected of supporting the royalist cause in the Civil War, were immediately detained by the parliamentarians. By this time, however, Sidney's attachment to the cause of constitutional liberties was already formed and he willingly joined the parliamentary side.

Made a captain of horse in the earl of Manchester's army on May 10, 1644, he soon became a lieutenant colonel and charged at the head of his regiment at Marston Moor (July 2), receiving serious wounds. In April 1645 he was given the command of a cavalry regiment in Oliver Cromwell's division of Sir Thomas Fairfax's army, and became governor of Chichester in Sussex in May.

In 1647 he again went to Ireland, where his brother was lord lieutenant, and was made lieutenant general of horse and governor of Dublin. But these appointments aroused jealousies in Ireland and Algernon was immediately recalled and placed at Dover as governor. In 1648, nominated against his will as a commissioner for the trial of Charles I, he refused to take part. He was deprived of his post at Dover in 1651, retired to Holland for some months, and, although appointed to the Council of State (1652), consistently withheld his support from Cromwell after the latter became lord protector (December 1653). He caused more offense in 1656 by taking the role of Brutus in performances of *Julius Caesar* at Penshurst.

On the restoration of the Rump of the Long Parliament (May 1659) he was again placed on the Council of State. When Charles II was restored to the throne, Sidney, then in Denmark, was not disposed to make his peace with the Stuarts and instead made his way to Rome (November 1660). Welcomed by Roman society, he enjoyed the tranquil pleasures of study, but in 1663 the attraction of the world of affairs proved too strong and he went to Brussels and to The Hague. His movements were closely watched by the English government and on the outbreak of the Second Dutch War (1665–67) attempts were made to seize or assassinate him. From The Hague he urged the invasion of England and after France had allied with Holland he offered at Paris to raise rebellion in England for 100,000 crowns. Nothing came of these schemes and in 1666 he retired to the south of France.

However, by 1677 the declining health of his father, who had continued to pay him a small maintenance, gave him compassionate grounds to return to England. The earl of Leicester died in November, but a protracted chancery suit over the will detained Sidney from returning to France. He now found himself the centre of liberal expectations, and was almost instantly drawn into the politics of opposition to Charles II. In the excitement of the "Popish Plot" (*see* ENGLISH HISTORY) Sidney, a welcome recruit to the Country Party, made a series of unsuccessful attempts to get into the House of Commons, aided by his friend William Penn. Sidney's opinions were similar to those of the earl of Shaftesbury, but they did not associate closely and it was as an individual, not as member of a faction, that Sidney received bribes in 1679 and 1680 from the French ambassador Paul Barillon to assist in undermining Charles II's government. Meanwhile Sidney worked on his *Discourses Concerning Government* (published in 1698 after his death), inspired, like John Locke's *Two Treatises,* by the move to exclude James, duke of York, from the succession, and by the menacing implications of Sir Robert Filmer's absolutist work *Patriarcha,* published for the first time in 1680.

Although relatively ineffectual as a politician, Sidney's reputation as a leader of popular opposition made it certain that the government would try to entrap him. His alleged but improbable implication in the Rye House Plot of 1683 to assassinate the king and the duke of York was therefore not unexpected. Denounced by informers, Sidney was arrested on June 26, 1683, and tried before Judge George Jeffreys in November. As in the trial of his fellow victim, Lord William Russell, the rules of evidence and procedure were heavily weighted against him. Passages from the manuscript of the *Discourses* were used to supplement Lord Howard of Escrick's testimony that Sidney believed in the lawfulness of resistance and had conspired for the death of the king. He was found guilty, and beheaded on Tower Hill, London, on Dec. 7, 1683. His remains were buried at Penshurst.

The example of Sidney's lifelong resistance to royal absolutism proved enduring, and his *Discourses* were a potent vehicle for liberal ideals. They became a popular "textbook of revolution" in the American colonies and were well-known in 18th century France and Germany. Although Sidney declared "I am persuaded to believe that God had left nations to the liberty of setting up such governments as best pleased themselves" it is misleading to call him a republican. His *Discourses* prescribed a limited monarchy, regulated by the concept of a voluntary civil contract, ruling in the interests of the free community of citizens in whom resided ultimate authority. Like the political philosopher James Harrington, Sidney recognized social and economic changes under the political tendencies of his time, and he lamented the extinction of the old nobility in the rising tide of middle class wealth. Sidney's liberalism was essentially aristocratic and a patrician hauteur was a commonly observed feature of his behaviour. It accounts for some of the vicissitudes of his life, as well as the nobility of his bearing on the scaffold.

See A. C. Ewald, *The Life and Times of the Hon. Algernon Sidney, 1622–1683,* 2 vol. (1873). (H. G. Ro.)

SIDNEY, SIR HENRY (1529–1586), English lord deputy of Ireland from 1565 to 1571 and from 1575 to 1578, was born on July 20, 1529, probably at Baynard's Castle, London. The eldest son of the soldier and courtier Sir William Sidney, he was brought up at court and enjoyed the favour of successive sovereigns. A gentleman of the privy chamber to Edward VI and knighted in 1550, Sidney's importance was so great that John Dudley, earl of Warwick (later duke of Northumberland), secured him as husband for his daughter Mary. Sidney signed Edward VI's will leaving his throne to Lady Jane Grey, but rapidly went over to Mary I and thus retained his position at court.

Sidney's sister Frances married (1555) Thomas Radcliffe, Lord Fitzwalter (afterward earl of Sussex), and when Fitzwalter went to Ireland as lord deputy in April 1556, Sidney accompanied him as vice-treasurer. He took part in the military expeditions (1556 and 1557) against the Scots in Antrim and acted as lord justice during Fitzwalter's absences. In 1559 he returned to England and was appointed lord president of the Welsh Marches. He resided much at court, until returning to Ireland as lord deputy (1565). Like Sussex, he played a direct, if equally inglorious, part in negotiating with Shane O'Neill (*see* IRELAND; *History*). Sidney encouraged O'Neill to believe that Elizabeth I would accept him as ruler of Tyrone, at the same time urging on the queen a harsh policy. But Sidney's military moves against O'Neill were unsuccessful and he was reduced to intriguing against him with the O'Donnells and with Sorley Boy MacDonnell. After the assassination (1567) of O'Neill by the MacDonnells, the lord deputy's claim to have conquered the Ulster leader was brazenly paraded in the preamble to the act (1569) of forfeiture which declared that most of the Northern Province belonged to the queen. But Sidney's weakness is shown in the fact that while parliament decreed the abolition of the title O'Neill, Turlough Luineach was proclaimed in succession to Shane without suffering adverse consequences.

At the Parliament of 1569–71, Sidney showed statesmanship in the care he took to avoid religious dissensions. With the Butlers as well as the Geraldines in alliance against the Dublin administration, an insistence on conformity to Protestantism would have made the war in the south more general and more difficult to terminate. Sidney contented himself with securing a temporary amendment of Poynings' Law, which enabled him to negotiate for the enactment of other parts of the government's program.

In his later periods of office in Ireland, Sidney made efforts to enlighten the London government about Irish conditions, to systematize Irish administrative arrangements, and to extend English rule in Ireland. He undertook long journeys in order to enforce his ideas and tried both to moderate fanatical English officials and to force recalcitrant Irish chiefs to observe the English laws. Yet his insistence on arbitrary taxation and impositions for the viceroy's forces caused much discontent and ultimately led to his recall. Thereafter he served the queen only as president of the Council of Wales and of the Marches, apparently giving general satisfaction. He died at Ludlow, Shropshire, on May 5, 1586.

Sidney's letters of state suggest he had statesmanlike qualities. He gave admirable advice to London on securing impartial administrations in Ireland and he expressed his dissatisfaction when the queen favoured Ormonde in his quarrel with Desmond. But as time went on he grew too sophisticated and complaisant. No judge of character, he was too ready to assist profit-making projects by needy and unscrupulous English adventurers. He was also rather vain of honours, and patronized antiquaries who gave him a fictitious pedigree. He resented the queen's failure to reward his Irish services, but showed little anxiety for a peerage,

which might have involved him in ruinous financial burdens.
(R. D. Es.)

SIDNEY, SIR PHILIP (1554–1586), the finest English example of the Renaissance ideal of the perfect gentleman. He was virile and cultivated: a soldier, statesman, courtier, poet and patron of scholars and poets. The eldest son of Sir Henry Sidney and Mary Dudley, he was born at Penshurst, Kent, on Nov. 30, 1554. On Oct. 17, 1564, he and his lifelong friend Fulke Greville were entered at Shrewsbury school. Sidney's training was based on the assumption that he would be heir to his uncle, the earl of Leicester. He visited Kenilworth, Leicester's home, in Aug. 1566 and with Leicester took part in Queen Elizabeth I's progress to Oxford. In 1568 he went to Christ Church, Oxford. As lord deputy Sir Henry was much in Ireland and Sidney spent some vacations with the Cecils: a match was proposed in 1569 with Sir William Cecil's daughter Ann, but came to nothing.

DETAIL FROM A PORTRAIT BY AN UNKNOWN ARTIST; PHOTO BY COURTESY OF THE EARL OF WARWICK

SIR PHILIP SIDNEY AT THE AGE OF 22

On May 25, 1572, Queen Elizabeth granted Sidney a licence to travel for two years to learn foreign languages. He left England in the earl of Lincoln's suite and reached Paris, where he lodged with the English ambassador, Sir Francis Walsingham, on June 8. The massacre of St. Bartholomew's day caused his departure for Frankfurt, where he lodged with the scholar-printer, Andrew Wechel, and met Hubert Languet, an ardent Huguenot who, like other mature scholars and men of affairs, conceived warm affection and admiration for Sidney. In the early summer, 1573, he went on to Heidelberg, Strasbourg and Vienna and in October left for Italy, spending some time in Venice where his portrait was painted by Paolo Veronese. In Oct. 1574 he returned to Vienna, and after a second visit to Prague in Feb. 1575, to England. He spoke French and Italian well, and his letter to Lord Burghley (Dec. 1574) shows that he had also a firm grasp of European politics.

Insufficient use was made of his training and exceptional ability during the next ten years. His father had once more been sent to Ireland, and this brought Sidney into touch with the earl of Essex, earl marshal for Ireland, who desired a marriage between Philip and his daughter, Penelope—the "Stella" of his sonnets. But nothing came of this, and Essex died in 1576. In 1577 Sidney was sent on an embassy to the emperor Rudolph II. He met Don John of Austria at Louvain, proposed a Protestant league to the emperor at Prague and on the way back was warmly received by William of Orange. On his return he defended his father's government of Ireland, particularly from the attacks of Lord Ormond, writing the *Discourse on Irish Affairs* for the queen. In 1580 he was bold enough to oppose the queen's proposed marriage to the duc d'Alençon in a *Letter to the Queen*. He was knighted in 1583 to enable him to receive the Garter as Prince John Casimir's proxy.

Sidney divided his time between his uncle's town residence, Leicester house, and Wilton, where his sister Mary, now countess of Pembroke, lived. He took part in the court festivities and composed *The Lady of May* for Leicester's entertainment of the queen at Wanstead in 1578. In this year he met Spenser at Leicester house and discussed with him and Edward Dyer the use of classical metres in English verse. Spenser's *The Shepheardes Calender* (1579) was dedicated to Sidney. During these years he himself wrote the *Arcadia, An Apologie for Poetrie* and *Astrophel and Stella*—some of the sonnets in this cycle would seem to have been written after Penelope Devereux's enforced marriage to Lord Rich toward the end of 1581. Sidney's literary output was the result of his lack of employment in serious affairs, and it is unlikely that his untimely death prevented further imaginative works.

In the autumn of 1583 he married Frances Walsingham; Elizabeth stood godmother to the daughter born in 1585. Sidney still desired active service and took an interest in the colonizing enterprises of Martin Frobisher, Richard Hakluyt and Sir Walter Ralegh. He advocated a direct attack on Spain, and was himself preparing to sail with Drake in 1585 when the queen recalled him and appointed him governor of Flushing. Leicester, in command of the English forces in the Netherlands, leaned heavily on his advice during the next difficult months.

In July 1586 Sidney made a successful raid on Axel, near Flushing; on Sept. 22 he was with a small force under Sir John Norris which Leicester ordered to intercept a convoy of provisions near Zutphen. According to Fulke Greville, Sidney cast off his cuisses because Sir William Pelham was without his, and so received the fatal bullet wound in his thigh. Greville is also responsible for the story that he refused a cup of water in favour of a wounded soldier with the words, "Thy necessity is yet greater than mine." Greville was not present, but both stories are in keeping with Sidney's character. He died at Arnhem on Oct. 17, 1586.

Sidney's death was an occasion for universal mourning. The most famous of some 200 elegies is Spenser's *Astrophel*, published, with others by the countess of Pembroke, Fulke Greville, Ralegh, Matthew Roydon and Lodowick Bryskett, in his *Colin Clouts Come home againe* (1595).

Writings.—None of Sidney's works was printed during his lifetime. Between 1577 and 1580 Sidney wrote the first version of his prose romance *Arcadia*, in five books or acts, for the entertainment of his sister and her friends. This version remained in manuscript until A. Feuillerat printed it from the Clifford manuscript in 1926. Between 1580 and 1584 Sidney embarked on a radical revision, using nearly all the old material, but enlarging books i and ii with many additional episodes and writing a new book iii, which breaks off in the middle of a sentence before he had reached the point where the old book iii began. This version was published as *The Countesse of Pembrokes Arcadia* (1590), probably under the supervision of Fulke Greville, who claimed that it truly represented Sidney's serious and moral intentions. In 1593 Hugh Sanford prepared a folio edition which included the 1590 version and books iii–v of the old *Arcadia* with some changes which may represent Sidney's intentions, but were probably made by his sister. This was the *Arcadia* known to countless later writers and readers. Sidney's early pastoralism seems to have been mainly influenced by Jacopo Sannazzaro's *Arcadia* (poems with short prose links) and his later epic narrative by Heliodorus' *Aethiopica* (a Greek novel with a complicated "Chinese box" structure of stories within the main story). The golden world of innocent shepherds and shepherdesses is combined by Sidney with a sterner world of violent action and crime. The main narrative concerns the adventures of two princes, Musidorus and Pyrocles, who fall in love with Pamela and Philoclea, the daughters of Basilius and Gynecia. The characters of the two girls are well differentiated and in her struggle with illicit passion Gynecia has been likened to Phèdre. There are some good comic and dramatic episodes, and many serious debates on such topics as justice, atheism and suicide. The sentences are long and laden with rhetorical devices, for example:

> There were hills which garnished their proud heights with stately trees; humble valleys whose base estate seemed comforted with refreshing of silver rivers; meadows enameled with all sorts of eye-pleasing flowers; thickets, which being lined with most pleasant shade, were witnessed so to by the cheerful disposition of many well-tuned birds; each pasture stored with sheep feeding with sober security, while the pretty lambs with bleating oratory craved the dams' comfort; here a shepherd's boy piping, as though he should never be old; there a young shepherdess knitting and withal singing, and it seemed that her voice comforted her hands to work, and her hands kept time to her voice's music.

Sidney's use of this style was deliberate. In all his work he observed the principle of decorum, suiting style to subject. That he could be direct is shown in this letter to his father's secretary:

> I assure you before God that if I know you do so much as read any letter I write to my Father, without his commandment, or my consent, I will thrust my dagger into you. And trust to it, for I speak it in earnest.

Many poems in which Sidney experimented in metrical forms are introduced into the *Arcadia;* they include a few sonnets. These, however, do not reach the high standard of those in his *Astrophel and Stella.* Sir Thomas Wyat and the earl of Surrey had introduced the sonnet into English poetry, but *Astrophel and Stella* was the first English *canzoniere*—a series of songs and sonnets telling a love story. Sidney's sonnets were partly autobiographical, but they were also indebted to Petrarch, Du Bellay, Ronsard, Desportes and others. His metre is extremely regular. The rhyme scheme of the octave is that adopted in Europe; Sidney usually followed Surrey in ending the sestet with a couplet. He often adopted Wyat's colloquial tone; for example,

> "Fool," said my Muse to me, "look in thy heart and write!"

The fondness for word play and the use of personification apparent in the *Arcadia* reappear here. More striking is the freshness he managed to infuse into the stale Cupid imagery.

> With how sad steps, o Moon, thou climb'st the skies,
> How silently, and with how wan a face!
> What, may it be that even in heav'nly place
> That busy archer his sharp arrows tries?

After Shakespeare's sonnets, *Astrophel and Stella* is the finest Elizabethan sonnet cycle. Thomas Newman published a faulty quarto edition, with preface by Thomas Nashe and some sonnets by other writers, in 1591. He followed this with a better text in the same year. The 1598 *Arcadia* folio offered a still better text and included *Certain Sonnets* and *The Lady of May.* To the 1613 folio was added *A Dialogue Between Two Shepherds. Two Pastorals* appeared in Francis Davison's *Poetical Rhapsody* (1602). (On the authenticity of these last two items, *see* W. Ringler, "Poems Attributed to Sir Philip Sidney," *Studies in Philology,* xlvii, pp. 126–151; 1950.)

Sidney seems to have had Stephen Gosson's *The Schoole of Abuse* (1579) in mind when he sprang to the defense of poetry, though the exact date of his treatise is not known. It was published in 1595, by W. Ponsonby as *The Defence of Poesie* and by H. Olney as *An Apologie for Poetrie,* and Ponsonby included it in the 1598 *Arcadia.* It is the first work to introduce the critical ideas of Renaissance theorists into England. Sidney's arguments for the lofty nature of poetry and against its detractors have been repeated countless times—partly by reason of the easy and persuasive style. He is urbane and courteous where Gosson was shrill and abusive. He wrote just before the great Elizabethan age of poetry and drama, and without the example of Shakespeare, he cannot be blamed for missing the English genius for tragicomedy. He praised the best English works available.

A Woorke Concerning the Trewnesse of the Christian Religion, translated from Duplessis-Mornay, was completed and published by Arthur Golding in 1587. Sidney was responsible for the first 43 psalms in the metrical versions completed by his sister. His translations of the first *Semaine* of G. Du Bartas and of the first two books of Aristotle's *Rhetoric* are lost. Sidney's letters, especially the Latin correspondence with Languet (trans. and ed. by S. A. Pears, 1845), and his three political treatises, not published in his lifetime, the *Discourse on Irish Affairs,* the *Defence of Leicester* and the *Letter to the Queen,* are of historical interest.

Sidney's *Complete Works,* including both versions of the *Arcadia,* were ed. by A. Feuillerat, 4 vol. (1912–26). The texts are not altogether satisfactory, and for his poems see *The Poems of Sir Philip Sidney,* ed. by W. A. Ringler (1961). A modernized text of *The Countess of Pembroke's Arcadia* with the linking passage in bk iii supplied by W. Alexander in 1621, and the sixth book, added by R. Beling in 1627, was ed. by E. A. Baker (1907).

Bibliography.—Fulke Greville's *Life of the Renowned Sir Philip Sidney* (1625) was ed. by N. Smith (1907). The best biography is M. W. Wallace, *The Life of Sir Philip Sidney* (1915); the works are more fully treated by M. Wilson, *Sir Philip Sidney,* 2nd ed. (1950). There is a full bibliography by M. Poirier, *Sidney: le chevalier poète élisabéthain* (1948). *See* also J. Buxton, *Sidney and the English Renaissance* (1954); J. W. Lever, *The Elizabethan Love Sonnet* (1956); R. W. Zandvoort, *Sidney's Arcadia: a Comparison between the Two Versions* (1929); Jean Robertson, "Sir Philip Sidney and his Poetry," *Elizabethan Poetry,* pp. 110–29 (1960). (J. Rn.)

SIDON (modern Saïda), once the chief city of Phoenicia, is the fourth largest city in Lebanon. Situated on the Mediterranean about 25 mi. (40 km.) SSW of Beirut, it had an estimated population of 32,200 in 1961. It is an agricultural trading centre as well as a trading and fishing port. It has a large Christian community as well as an old Jewish community and quarter. Since 1950 the city has been the Mediterranean terminus of the pipeline from the Saudi Arabian oil fields.

History.—Sidon, one of the oldest Phoenician cities, was founded in the 3rd millennium B.C. and became prosperous in the 2nd. It was burned by the Philistines in the 12th century B.C. but rapidly regained its strength and scattered its colonies in the eastern Mediterranean (including Cyprus). It is frequently mentioned in Homer and in the Old Testament. It was ruled in turn by Assyria, Egypt, Persia, Alexander the Great, the Seleucids of Syria, the Ptolemies of Egypt, and the Romans. At this time Sidon was famous for its purple dyes and glassware. Herod the Great embellished the city, and Jesus visited its neighbourhood.

During the period of the Crusades Sidon changed hands several times, and more than once it was destroyed and rebuilt. It was destroyed again by the Mongols in 1260. Under Turkish rule almost continuously for 400 years from 1517, it blossomed into vigorous existence in the 17th century under Fakhr al-Din II, a semi-independent Druze amir, who encouraged and protected its commerce. In 1791, however, the governor of Lebanon, Ahmad al-Jezzar, drove the French merchants from its gates, thereby largely killing its trade. In 1837 it was ravaged by an earthquake but rebuilt. The later history of the city is inseparable from that of the rest of Lebanon (*q.v.*).

Archaeology.—Because much of the ancient city lies under the modern town, the archaeological history of Sidon is obscure. A large necropolis discovered southeast of the town in 1855 yielded numerous sarcophagi including those of two Sidonian kings, Eshmunazar and Tabnith, both with valuable Phoenician inscriptions. In 1887, 17 more sarcophagi were discovered including the famous "Alexander" sarcophagus, depicting battle and hunting scenes, now at Istanbul. The Beirut Museum possesses 31 more sarcophagi and a rich collection of jewelry of the 5th–4th century B.C. found in some of them during further excavations carried out in the necropolis in 1963–64. Since 1961 the Lebanese General Directorate of Antiquities has undertaken systematic excavations at the site of the Persian palace and in the temple of the god Eshmun, discovered in the 19th century 2.8 mi. (4.5 km.) N of the town.

The ancient city's sea mole and wall can still be located, and it still has the twin harbours used in antiquity and two castles of the crusader period. *See* also Phoenicia.

Bibliography.—F. C. Eiselen, *Sidon* (1907); O. Hamdy Bey and T. Reinach, *Une Nécropole royale à Sidon* (1892); E. Kukahn, *Anthropoide Sarkophage in Beyrouth* (1955). (R. D. B.)

SIEBENGEBIRGE ("Seven Hills"), actually a group of about 40 wooded hills of volcanic origin in Germany between Königswinter on the right bank of the Rhine and the Cologne-Frankfurt am Main *Autobahn.* The district is a popular tourist resort and a nature reserve. The hills form the northwestern part of the Westerwald region. The seven principal hills seen from Bonn (whence the name) are: Drachenfels (1,053 ft. [321 m.]), reached by rack railway from Königswinter and surmounted by a ruined castle; Wolkenburg (1,063 ft.); Petersberg (1,086 ft.), with a motor road to the summit hotel which until 1952 was the seat of the tripartite Allied High Commission; and, to the south, Ölberg (1,522 ft. [464 m.]), the highest of the group; Löwenburg (1,493 ft.); Lohr-berg (1,427 ft.); and Nonnenstrom-berg (1,101 ft.). Quarries yield basalt for building (*e.g.,* Cologne and Limburg cathedrals) and paving, on the lower slopes behind Königswinter are some of the northernmost vineyards in Europe.

(R. E. Di.)

SIEBOLD, KARL THEODOR ERNST VON (1804–1885), German zoologist who investigated the morphology and life history of lower animals, was born in Würzburg on Feb. 16, 1804. After practising medicine briefly, Siebold was professor of zoology at Erlangen, Freiburg, Breslau and Munich. In 1848 he founded the *Zeitschrift für wissenschaftliche Zoologie.* He died at Munich on April 7, 1885.

Siebold was probably the first to discover that the Protozoa

consist of a single independent cell. This important finding emphasized the cell as a basic unit of living matter, and suggested that evolution from one- to many-celled organisms, and also embryonic development, involved a progressive specialization and division of labour among cell units. Siebold also clearly showed that eggs of some insects were normally parthenogenic, developing without fertilization. His studies on the life histories of tapeworms demonstrated to medical men of his day the bearing of basic zoological research on certain clinical problems. His work on the anatomy of invertebrates was one of the first important texts on the comparative anatomy of lower animals. His major works include *Lehrbuch der vergleichenden Anatomie der Wirbellosen Thiere* (1845–48; Eng. trans., W. I. Burnett, *Anatomy of the Invertebrata*, 1854); *Überdie Band-und Blasenwürmer* (1854); *Wahre Parthenogenesis bei Schmetterlingen und Bienen* (1856; Eng. trans., W. S. Dallas, *On a True Parthenogenesis in Moths and Bees*, 1857). (H. H. S.)

SIEDLCE, a town in Warsaw *wojewodztwo* (province), Poland, a district capital, and the seat of a Roman Catholic bishopric, lies 55 mi. (89 km.) E of Warsaw. Pop. (1960) 32,300. As a settlement situated on the Podlasian plain at the meeting place of trade routes, Siedlce obtained town rights *c.* 1557. Its most flourishing period was during the 18th century, when its owners, the Oginski family, transferred there their residence (the present bishop's palace) and church. After the third partition of Poland (1795) Siedlce was occupied by Austria. From 1809 to 1815 it was included in the duchy of Warsaw, and then in the Polish kingdom, dependent on Russia. It was returned to Poland in 1918. During World War II five Nazi concentration camps were situated there. Siedlce is on the Warsaw–Moscow road and railway and is an economic centre of the southeastern part of Warsaw *wojewodztwo*. Industry, only poorly developed, is represented by food and metalworking factories. (T. K. W.)

SIEGBAHN, KARL MANNE GEORG (1886–), Swedish physicist, awarded the 1924 Nobel Prize in Physics for his discoveries and investigations in X-ray spectroscopy, was born in Örobro, on Dec. 3, 1886. He obtained his doctor's degree in 1911 from the University of Lund. He served as assistant to J. R. Rydberg in the physics institute of the university from 1907 to 1915 and in the latter year was appointed deputy professor of physics. On Rydberg's death in 1920 he succeeded to the chair. In 1923 he became professor of physics at Uppsala and in 1937 he accepted the corresponding chair at Stockholm and became director of the Nobel Institute of Experimental Physics of the Swedish Royal Academy of Sciences, Stockholm. His early researches were mainly concerned with problems in electricity and magnetism, but after 1914 he was engaged in the systematic investigation of the X-ray spectra of the different elements. In 1916 he discovered a new spectral series, the long-wave M-lines. With the aid of high-vacuum spectrographs and other apparatus of his own invention he carried the measurement of wavelengths to an extraordinary level of accuracy. In 1924 he and his colleagues succeeded in furnishing proof of the diffraction of X rays in prisms; he later investigated the immediate field between X rays and ultraviolet rays. In the 1960s he was an honorary member of the International Committee on Weights and Measures after more than 25 years service on that body.

See S. Lindroth, *Swedish Men of Science, 1650–1950* (1952). (W. J. Br.)

SIEGBURG, a town of West Germany in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany, lies on the Sieg River 7 mi. (11 km.) NE of Bonn by road. Pop. (1961) 33,974. Siegburg grew around the abbey founded in 1064 by St. Anno, Archbishop of Cologne, on the summit of the Michaelsberg, a volcanic hill. The Church of St. Servatius, dating from about 1150, contains an important treasury of Romanesque art. Siegburg, which has a large factory producing synthetic fibres, is skirted eastward by the Cologne–Frankfurt am Main *Autobahn*. (K. Ku.)

SIEGEN (Sechten), **LUDWIG VAN** (1609–*c.* 1680), Dutch engraver, the inventor of mezzotint (*q.v.*), was born in Utrecht. He spent most of his early life in the services of the landgravine Amelia Elizabeth and the landgrave William of Hesse-Kassel. He lived in Amsterdam from 1641 to about 1644 and here it is supposed he was influenced by Rembrandt. Later he served Johann Philipp von Schönborn, elector of Mainz, and the duke of Brunswick while in Wolfenbüttel, where he is mentioned for the last time in 1676. His first mezzotint was a portrait of Amelia Elizabeth, in the dedication of which he claims the invention of the process as one not of lines, but of dots. There are seven known rouletted mezzotint plates by him.

See A. M. Hind, *History of Engraving and Etching, from the 15th Century to the Year 1914* (1923). (H. Es.)

SIEGEN, a town of West Germany in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany, lies on the Sieg River 70 mi. (113 km.) ESE of Cologne by road. Pop. (1961) 49,404. The town's two castles were formerly residences of branches of the House of Nassau and the lower (Orange-Nassau) castle has an interesting royal crypt. The late Romanesque Nikolaikirche (13th century) is hexagonal in shape and has a magnificent font. Siegen is the centre of the Siegerland iron ore mining district, and has metalworking and machine-building industries, and colleges of mining and technology. The Flemish painter Rubens was born there.

SIEGFRIED (Sigurd), a figure from the heroic literature of the ancient Teutons, known to us as Sigurd in Old Norse and as Siegfried in German literature, although these two branches of the tradition do not always agree. He plays a part in the story of Brunhild (*q.v.*), in which he meets his death, but in other stories he is the leading character and triumphs. A feature common to all is his outstanding strength and courage. One story tells of his fight with a dragon, and another of how he acquired a treasure from two brothers who quarreled over their inheritance. These two stories are combined into one in the *Edda* (*q.v.*) and told in detail, whereas in German, where they are kept entirely separate, the information is scant and largely contained in allusions. Siegfried plays a major part in the *Nibelungenlied* (*q.v.*), where this old material is used but much overlaid with more recent additions. *Das Lied vom hürnen Seyfrid,* not attested before about 1500, still retains it in identifiable form, although the poem's central theme is the release of a maiden from a dragon; and an *Edda* poem tells how Sigurd awakened a maiden, a valkyrie, from a charmed sleep. Here, too, many critics have tried to establish a connection between German and Norse; not only, however, are there many important differences, but there is great doubt, on internal evidence, about the antiquity of both poems.

In the original stories Siegfried was presented as a boy who, although of noble lineage, grew up bereft of parental care; this shows through clearly, although in the full accounts in both Norse and German it is overlaid with elaborate accounts of his courtly upbringing. As with Brunhild, it is still disputed whether the figure is of mythical or historical (Merovingian) origin.

See *Das Lied vom hürnen Seyfrid,* edited by K. C. King (1958). (K. C. K.)

SIEMENS, a family best known as engineers, inventors and manufacturers in the electrical industry.

Werner von Siemens (1816–1892), the chief founder of the electrical firm of Siemens and Halske, was born on Dec. 13, 1816, at Lenthe, Hanover. Between 1838 and 1848 he held a commission in the artillery, was entrusted with many specialized works and in particular became acquainted with the recently developed electric telegraph. In 1847 he founded, together with a skilled mechanic, J. G. Halske, the firm of Siemens and Halske for the manufacture of telegraphic apparatus. This firm under Siemens' guidance became one of the most important electrical undertakings in the world, with branches in different countries of which those in England and Russia were particularly important. It carried out many large telegraphic projects and later expanded into other electrical fields, as new applications of electricity were developed.

Many of Werner von Siemens' inventions relate to telegraphic apparatus. He used gutta-percha as an insulant for telegraphic cable in 1847; this form of insulation was later widely used for electric light cables. The Siemens armature, which he invented

in 1856 for use in telegraphy, afterward found further application in larger generators for electroplating and lighting and, following the invention of the ring armature, was modified by F. von Hefner-Alteneck, Siemens' designer, into the basic form of the modern armature. One of the most important of Siemens' discoveries was that of the dynamo-electric principle, the principle governing the self-excitation of the dynamo. This idea was also put forward by C. A. Varley and by Sir Charles Wheatstone about the same time, but Siemens appears to have more fully appreciated the possibilities of the invention and was certainly more responsible for their development. He died at Charlottenburg, Berlin, on Dec. 6, 1892.

Sir William Siemens (Karl Wilhelm; 1823–1883), brother of Werner, is known for his work in electricity and in the application of heat. In both fields he combined the functions of innovator, manufacturer and successful man of business. He was born at Lenthe, Hanover, on April 4, 1823. After attending the University of Göttingen he entered, as a pupil, the manufacturing concern of Count Stolberg at Magdeburg. At the age of 19 he first visited England in the hope of introducing an electroplating process invented by himself and Werner, which he succeeded in selling to Messrs. Elkington of Birmingham. He returned to Germany, but in 1844 was again in England, this time with another invention, the "chronometric," or differential, governor. Finding that British patent law afforded the inventor a protection then lacking in Germany, he henceforth made England his home.

The next few years were spent in trying to develop his inventions, of which at this time his water meter was commercially the most successful. His activities made him a respected figure in scientific circles: his paper "On the Conservation of Heat Into Mechanical Effect," read to the Institution of Civil Engineers in 1853, gained him the Telford medal, and in 1862 he was elected a member of the Royal society. William's chief work in the field of heat was concerned with regenerative heating and consequent improvements in steelmaking processes. He invented the regenerative condenser in 1848 and, together with his brother Friedrich, first tried to apply it to the steam engine, using the heat from the regenerator to preheat the boiler feed water. When this did not meet with success, other applications were sought and the idea occurred of applying the principle to furnaces, using the heat regained from the flue gases to heat the air supply to the furnace. This was patented in Friedrich Siemens' name in 1856 and met with great success for use both in glassmaking and in steel manufacture. Later the use of gas instead of solid fuel greatly extended the use of the regenerative furnace.

At that time the quality and reliability of steel was much inferior to that of iron and Siemens did much to develop steelmaking processes, using a large-scale trial plant equipped with regenerative furnaces. This work led to the Siemens-Martin process, shown at the Paris exhibition of 1867, and to the founding of the firm of Landore-Siemens, which was established for the application of the process.

In the field of electricity William, though making no great inventions, became an acknowledged authority and leader. From 1848 onward he represented the firm of Siemens and Halske in London, and when the separate firm of Siemens Brothers was established in 1865 he became a partner and director. At first the chief business was the erection of overland telegraph lines and the laying of submarine telegraph cables. William was, however, in constant close liaison with all the ideas and projects of his brother Werner in Berlin and, when the latter discovered the dynamo-electric principle, William introduced it to England by reading to the Royal society, in Feb. 1867, a paper entitled "On the Conversion of Dynamical Electric Force Without the Aid of Permanent Magnetism." Gradually in the late 1870s and 1880s the electric-light side of the business grew. One of the last projects with which William was associated was the Portrush electric railway in the north of Ireland, opened in 1883, which utilized water turbines driving a Siemens dynamo. The power so produced was transmitted to another machine acting as a motor on the tramcar. William Siemens was knighted in 1883 and died in London on Nov. 19 of the same year.

Alexander Siemens (1847–1928), nephew of William, was born in Hanover on Jan. 22, 1847. In 1867 he went to England, where he worked first in the workshops of Siemens Brothers at Woolwich, and consequently in the erection of the Indo-European telegraph line in Persia (1868) and in the laying of the Black sea cable (1868). In 1878 he became a naturalized British subject. The following year he took over the management of the electric-light department of Siemens Brothers, and was responsible for the installation of electric light at Godalming, Surrey, the first English town to be so lighted. Like many other members of the family, Alexander patented several inventions. After the death of Sir William he became a director of the company, a position he retained until 1918. He took an active part in public activities associated with his profession, was a member of several important committees and was twice president of the Institution of Electrical Engineers. He died at Milford-on-Sea, Hampshire, on Feb. 16, 1928. (M. K. W.)

SIENA, a city and archiepiscopal see of Tuscany, Italy, and capital of the province of Siena, lies 59 mi. (95 km.) S of Florence by rail. Pop. (1961) 64,383. Siena was the site of Etruscan and Roman settlements, and remains essentially a medieval town. Standing on three small hills, its medieval walls and gates enclose brick and stone buildings and narrow climbing streets which twist to reveal the green Tuscan country beyond. The oldest examples of Sienese architecture, including parts of the cathedral which stands on the southwesterly of the three hills, are Romanesque in style; a number of early campaniles show Lombard forms. The predominant type of civic building in this period was the fortified inhabited tower (*casatorre*), such as the Torre dei Forteguerri. To a later, Gothic era belong the enlarged cathedral and its baptistery, a number of churches, and many palaces; much of this building is in a mixture of brick and stone. Probably the oldest of these palaces is the Palazzo Tolomei, built before 1205; others are those of the Buonsignori, Sansedoni, Salimbeni, and, finest of all, the Palazzo Pubblico (1297–1310), the seat of civil government. The lowest part of the Palazzo Pubblico's facade is in stone while the upper part, in brick, contains windows grouped in threes and set in pointed arches, the whole being topped with ornamental battlements; the interior is decorated by the great masters of Sienese painting (*see* below). To one side rises the slender 334 ft. (98.75 m.) bell tower, the Torre del Mangia (1338–48); at the foot of the Palazzo is a chapel (1352–76) begun as a public thank offering after the terrible plague of 1348. The Palazzo and its tower stand along one curved side of the shell-shaped Piazza del Campo, the centre of Siena's civic life set in a hollow among the city's hills.

The cathedral, begun in the 12th century in the Romanesque style, was later transformed into one of the finest examples of the Italian Gothic. Its nave (293 ft. long) was begun in the 13th century and the greater part of the church, built inside and out of black and white marble, was finished, together with the baptistery and the fine campanile, in the following century. It was then decided to turn the nave into the transept of an enormous new cathedral, but that scheme was abandoned in 1355 after the crisis which followed the Black Death, and only a few ruined walls bear witness to it. The splendid west front (1376 onward; with modern restoration) resembles one begun considerably earlier at Orvieto, and is decorated with a multitude of columns and statues. Inside, Niccolò Pisano's octagonal pulpit (1265–68) and the marble floors which include Old Testament scenes designed by Domenico Beccafumi are outstanding. The frescoes in the chapel of St. John Baptist were painted (1504) by Pinturicchio, as were those (1503–08) of the life of the Sienese Pope Pius II in the Piccolomini Library adjoining the cathedral; the library was founded in honour of Pius II by his nephew, Cardinal Francesco Piccolomini, later Pius III. Beneath the cathedral, serving as its crypt, is the Church of S. Giovanni which has a beautiful but incomplete 14th-century facade and a fine outer flight of marble steps (1451); inside is a magnificent font with bas-reliefs by Jacopo della Quercia, Donatello, Lorenzo Ghiberti, and other 15th-century sculptors.

Siena is famed for its fountains: the Fonte Branda, already

BY COURTESY OF THE ITALIAN STATE TOURIST OFFICE—CHICAGO

(LEFT) THE MANGIA TOWER OF THE PALAZZO PUBBLICO AND (CENTRE) THE CAMPANILE OF THE CATHEDRAL RISING ABOVE THE CITY OF SIENA

existing in the 11th century and immortalized by Dante (*Inferno*, xxx, 78), the Fonte Gaia, and the Fonte Nuova. Siena's churches are especially notable for their paintings: for example, the 13th-century brick Church of S. Domenico, with a contemporary portrait of St. Catherine of Siena by Andrea Vanni (*c.* 1332–1414); Sta. Maria dei Servi, with Matteo di Giovanni's "Massacre of the Innocents" (1491); and S. Agostino with works by Simone Martini, Matteo di Giovanni, and others. That Siena's 15th-century architecture was mainly inspired by Florence is shown by the Palazzo Piccolomini, the Palazzo Spannocchi, the Loggia del Papa, and other early Renaissance buildings. Later monuments include the Church of Sta. Maria di Provenzano designed by Schifardini (1594); that of S. Agostino, rebuilt in 1755 by L. Vanvitelli; the theatre built from Bibiena's designs in 1753 (restored 1951); and the Teatro Rozzi erected in 1816 by the Congrega dei Rozzi, a company which dated from the 16th century and had an important place in Italian theatrical history.

Since building activity was largely suspended in the 16th century and because the modern quarters have developed outside the walls, Siena's medieval character remains largely unspoiled and the town now flourishes on the resultant tourism. Visitors come especially to see the Palio delle Contrade, the famous horse races of medieval origin which are held yearly on July 2 and Aug. 16 in the appropriate setting of the Piazza del Campo, amid colourful festivities. Siena is connected by road, rail, and air with Rome, and by road and rail with Florence, Empoli, Orvieto, Grosseto, and Arezzo. Many of the greatest masterpieces of Sienese painting and sculpture are in the Pinacoteca Nazionale, the Palazzo Pubblico, and the Museo dell'Opera del Duomo, which contains Duccio di Buoninsegna's "Maestà." The Museo Etrusco Senese houses archaeological treasures; St. Catherine's rooms are in the Santuario Cateriniano; and the Palazzo Chigi is famous for its collection of musical instruments and its summer school of music, the Accademia Musicale Chigiana. The university dates from the 13th century and maintains faculties of law, medicine, and pharmacy. The city is an administrative and agricultural centre, and manufactures chemicals, fertilizers, and machinery. Its wines and sweet cakes (*panforte*) are famous. Siena escaped serious damage in World War II and was liberated from the Germans in 1944. It has survived as a charming provincial town of great beauty.

Art.—After defeating the Florentines in 1260 the Sienese enjoyed nearly a century of prosperity during which they lavished great wealth upon the creation of a graceful city. The Gothic cathedral was adorned with two masterpieces, the octagonal pulpit carved (1265–68) by Niccolò Pisano and the "Maestà" painted (1308–11) by Duccio to celebrate the 50th anniversary of the victory of 1260, for the Virgin was the protector of the Sienese whose coins were from 1279 inscribed *Sena vetus civitas Virginis.* Niccolò Pisano and his son Giovanni Pisano (*qq.v.*), who also worked in Siena (1284–99), may be considered among the originators of Italian Gothic sculpture. Among their Sienese followers were Camaino di Crescentino, creator of Siena's Fonte Nuova (1298); his son, Tino di Camaino, sculptor of the tomb of the emperor Henry VII in Pisa (1315); Lorenzo Maitani (1275–1330), architect of Orvieto cathedral; and Lando di Pietro, who was entrusted in 1339 with the ambitious but abortive scheme to enlarge Siena's cathedral. Like this cathedral project, the grandiose civic centre was intended to outdo Siena's rivals, especially Florence. The civic centre was placed distinctly apart from the ecclesiastical; the Piazza del Campo and the Palazzo Pubblico were the product of communal pride and patronage, as was their decoration. The theme of Duccio's "Maestà" was repeated in the frescoes in the great council chamber of the Palazzo Pubblico, where the Virgin (1315) by Simone Martini (*q.v.*) faces his equestrian portrait of the conquering Sienese captain, Guidoriccio da Foligno (1328). Frescoes of Good and Bad Government (*c.* 1339) by Ambrogio Lorenzetti (*q.v.*) are in the Sala della Pace of the same building. Later, Jacopo della Quercia carved one of the finest fountains of his time, the Fonte Gaia (1419) the remains of which are in the Palazzo Pubblico; a reproduction (1868) stands in the Piazza del Campo.

Until the time of Duccio di Buoninsegna (*q.v.*) Sienese painting was a flourishing but provincial school working in the Romanesque tradition. Duccio produced beautiful and tender Byzantinesque Madonnas, often with the child pulling playfully at his mother's headdress. He began the transformation of the Sienese school from a hierarchic Byzantine stiffness to a looser, flowing, linear style. Simone Martini painted in a more vivacious, poetic, and original manner, his hands and draperies more freely drawn. Simone, like his brilliant contemporaries the brothers Pietro and Ambrogio Lorenzetti, painted what came to be the typical Sienese Madonnas. Siena played an important part in the development of Renaissance painting, but the death of Simone Martini and the Lorenzetti brothers coincided with Siena's economic decline and the plague of 1348. Thereafter Sienese painting took the path not of the rationalism and scientific inquiry connected with the Renaissance in Florence but of the mysticism of Siena's two great saints, Catherine and Bernardino (*qq.v.*). Siena's painters maintained their somewhat conservative Gothic style and their colourful linear rhythms, achieving an elegant, spiritual beauty. Perhaps only the lyrical designs, reminiscent of Ambrogio Lorenzetti, produced by Stefano di Giovanni, known as Il Sassetta, and the strange angular landscapes of Giovanni di Paolo compare with earlier Sienese masterpieces. Taddeo di Bartolo (*c.* 1393–1422), who executed new frescoes for the Palazzo Pubblico, Domenico di Bartolo (*c.* 1400–47), Sano di Pietro (1406–81), and others produced work of lasting beauty, but the school was in decline during the 15th century.

Sienese sculpture was carried to its height by Jacopo della Quercia. Among those who followed him were three painter-sculptors, all to some extent receptive to Florentine influences: his pupil Lorenzo Vecchietta (*c.* 1412–80); Neroccio di Landi (1447–1500); and Francesco di Giorgio (*q.v.*). Sienese painting required new life and inspiration, and these were supplied to some degree by Domenico Beccafumi (*q.v.*) and Giovanni Antonio de' Bazzi, known as Sodoma, who arrived in Siena in 1501 and worked mainly there until his death in 1549. For the rest, the 16th century saw the disappearance not only of Siena's political independence but also of its artistic originality.

SIENA PROVINCE (area 1,475 sq.mi. [3,820 sq.km.]; pop. [1961]

272,111) lies in the central Tuscan hills with the Chianti Hills to the east. The province is drained mainly by the Ombrone River and its tributaries. The beautiful countryside is fertile and well wooded in places, with considerable areas of rather desolate landscape, bleaker than other parts of Tuscany. Though there has been a small development of chemical and light industries, the province is primarily an agricultural area centred on the market town of Siena. About two-thirds of the population is engaged in agricultural activities: cattle raising, the cultivation of grain and olives, and above all the production of wine, Chianti being perhaps the best-known of Italian wines. The population, always sparse, has recently been drifting away from the depressed areas of the countryside. There are no other real towns, and only a few of the 36 communes have over 10,000 inhabitants; the most notable centres are Poggibonsi, Montepulciano, and San Gimignano (*q.v.*), famous for its many towers.

History.—An Etruscan site and a Roman colony, Siena lay at the point where the road from Rome to the north, the Via Francigena, met a route running eastward toward Arezzo and the Adriatic ports. The Roman settlement, known as Sena Julia, was largely destroyed, and Siena grew again, perhaps as a defensible point of refuge from invading barbarians during the disintegration of the Roman Empire. By the 7th century Siena had a bishop, and under the Lombard kings was ruled by royal representatives, *gastaldi*, whose title changed in Carolingian times to that of count. The Lombard ruling class apparently fused with those whom it ruled, and the counts and other feudal lords achieved independence of the emperor. This local aristocracy seized power in the surrounding countryside (*contado*) but had to share its predominance with the bishops who, during the 11th century, made themselves independent, at least within the city.

Siena's fertile *contado* produced oil, wine, and grain. The *mezzadria* system, by which the landowner provided the peasant with tools and seed, receiving half the produce in return, was being practised near Siena as early as 821. This was one way of financing the process of land reclamation which, especially through drainage schemes, increased Tuscany's agricultural productivity and helped to make possible the growth of urban life. The townsfolk increased their prosperity and power, securing the highways on which their trade depended by subduing the lords and castles of the *contado*. Early in the 12th century they replaced the rule of the counts and bishops with that of their own free commune and consuls (*see* COMMUNE [MEDIEVAL]). This amounted to rebellion against the emperor. In 1186 the emperor Frederick I's son, the future emperor Henry VI (1191–97), successfully besieged Siena; he then confirmed Siena's position as an imperial vassal with rights of self-government through its consuls, but freed the smaller towns and nobles of the *contado* from dependence upon Siena. When Henry VI was succeeded by an infant son in 1197, Tuscany revolted and Siena reasserted control over the *contado*, so becoming involved once more in the long-standing and primarily economic conflict with Florence. Florence was anti-imperial, or Guelph; Siena became the centre of Tuscan Ghibellinism, but imperial support did not bring victory against Florence.

In the 13th century Sienese merchant companies, favourably placed on international routes, were trading in London and Bruges and at the fairs of Champagne, where their agents acquired Flemish cloth. Siena became an important centre for banking and was especially active in transferring ecclesiastical incomes for the popes, who were often resident at nearby Viterbo. High interest rates and profits brought great fortunes; the Magna Tabula of the Buonsignori was the greatest merchant-banker company of the time. During the 13th century Siena fought to control Grosseto in the unfounded hope that a port could be opened up nearby at Talamone, and in the 14th century the city declined in the face of competition from Florence which was in a better position geographically and demographically to develop its industry and trade.

Commercial prosperity brought social and political unrest and the emergence of an urban opposition to the ruling oligarchy. From 1199 the consuls were replaced by a *podestà*, usually from another town, who governed for one year, while an oligarchic consular class of nobles, the *magnati* or *grandi*, who lived and traded in the town and possessed feudal estates outside it, continued to exercise real power. A revolt of the people (*il popolo*) followed a Sienese defeat by the Florentines in 1235, and in 1240 the oligarchy of the *grandi* gave way to a council of 24 (12 *grandi* and 12 *popolani*) which ruled for about 30 years. The death of the emperor Frederick II in 1250 was followed, in 1253, by an uprising which increased the strength of the *popolo* through a modification of the powers of the *podestà* and the creation of a *capitano del popolo*. Siena reached the height of its political success when on Sept. 4, 1260, an army, which included forces provided by Frederick II's illegitimate son Manfred, crushed the Florentines at Montaperti.

Siena's triumph was short-lived. Commercial prosperity suffered when the pope ordered the sequestration of the goods of the church's Ghibelline enemies, and hard-hit Sienese merchants, who thus lost their goods and credits, began to go into exile; some even financed the Guelph leader, Charles of Anjou, who defeated the last imperialists, Manfred and Conradin, at Benevento (1266) and Tagliacozzo (1268) respectively. Now Florence was triumphant, and in Siena there was party strife as *magnati* and merchants gradually abandoned the Ghibelline cause. Siena became Guelph after the Ghibelline leader, Provenzano Salvani, was defeated in 1269. In 1277 the *magnati*, such as the Tolomei, Salimbeni, and Piccolomini, turbulent and still in part Ghibelline, were excluded from government office. For nearly 80 years a merchant oligarchy, Guelph and closely allied to Florence, maintained Siena's prosperity and embellished the city. The republic was ruled by a council with a membership fixed in 1287 at nine, the *nove*. Those eligible for office, the *noveschi*, formed a genuine oligarchy; not only nobles, but lawyers, doctors, artisans, and others were excluded. The *noveschi*, many of them risen out of the *popolani*, were often middle-class or "new" men, others were rich or socially well-established; some owned both town and country property, and some were connected by marriage or interest to the *magnati*. Distinctions were seldom clear-cut, for *magnati* had always participated in the merchant-banking companies and grown rich in trade, just as many merchants used their wealth to purchase country estates.

The oligarchic rule of the *nove* provided experience and continuity in government but involved endless conspiracy on the part of those excluded. Affairs largely beyond the commune's control produced discontent: late in the 13th century Florence defeated the Pisans and its economy boomed; early in the 14th century Italy experienced an overall economic decline which was reflected in Siena; Tuscany was visited by wars, famines, and in 1348 by the Black Death. In 1355 the *popolo* allied with the *magnati* and overthrew the *noveschi* regime, establishing a popular government of 12, the *dodici popolani*, representing a class rather inferior to the *noveschi*, who were now excluded from government. Siena entered a disturbed era of faction and revolt. In 1368 the *magnati* party, the *monte dei gentiluomini*, ejected the *dodici popolani* but were themselves overthrown and replaced by successive coalitions of the *dodicini*, the *noveschi*, and a new party, the *monte dei riformatori*. The *riformatori*, representing lower middle-class or artisan but not proletarian interests, governed through a further period of violence until upset in 1385 by a party representing even lower social strata, the *monte del popolo*. Henceforth, Sienese politics consisted of successive predominantly middle-class coalitions; for decades there was discord but no major revolution. During the period after 1387, Siena survived a new war with Florence only by accepting the despotic rule of Gian Galeazzo Visconti, Lord of Milan. But from 1409, when King Ladislas of Naples advanced into Tuscany, Siena and Florence formed a republican alliance which excluded both the Milanese and Neapolitan despots from Tuscany, and lasted into the 16th century. War and civil strife continued with brief interludes, for Siena was never sufficiently industrialized to prevent the steady enfeeblement of its commerce and banking, or to destroy the power of the nobles who brought turbulence to city politics and wrought havoc in the *contado*, where they reasserted their independence. Losing its place in the socioeconomic pattern of northern Italy, Siena reverted to a predominantly agricultural economy characteristic of southern Italy, and seems to have turned to religion; this was

the period of Siena's mystic saints, Catherine and Bernardino.

Politically, the urban ruling class was slowly transformed into a new aristocracy based on political privilege and increasing investments in land. After 1385, the *gentiluomini* and *dodicini* were mainly excluded from government, while entrance to the *monti* and thus to the full citizenship of the governing class was increasingly restricted. From this sterile situation, in which social mobility was reduced to a minimum and the parties ceased to reflect economic differences and became like hereditary castes, there finally emerged a despot. In 1487 an exiled member of the *noveschi* party, Pandolfo Petrucci, succeeded in driving out the government. Power in Siena was now vested in a *balìa*, or committee, in which the Petrucci were predominant, a constitutional arrangement cloaking Pandolfo's tyranny, a rule secured by a policy of lies, banishments, and assassinations. From 1494 Italy was a battlefield for French and Spanish armies; in a difficult situation Pandolfo managed to preserve his control until his death in 1512 and his regime was continued by his family until 1524.

Siena was now unable to preserve its independence. In 1526 an army sent by the Florentine pope, Clement VII, was defeated outside the walls but Siena had to seek protection from Clement's enemy, the emperor Charles V. In 1530 Charles sent a Spanish garrison to defend Siena, but protection was transformed into domination and, after a number of insurrections, the Sienese succeeded, with French help, in expelling the Spaniards in 1552. Siena was of strategic importance to both French and Spaniards, and in 1554 the Spaniards, supported by the Florentines, began a long siege which lasted until April 1555, when Siena's French garrison surrendered; the town's population had been reduced from about 40,000 to 8,000. Many surviving Sienese went into exile, and in 1557 Philip II of Spain ceded Siena to Cosimo I de' Medici, ruler of Florence. For two centuries Siena retained a separate administration but its history increasingly merged with that of Florence, Tuscany, and finally Italy.

SIENKIEWICZ, HENRYK (pseudonym LITWOS) (1846–1916), Polish author of novels which achieved great popularity, and winner of the Nobel Prize for Literature in 1905, was born on May 5, 1846, at Wola Okrzejska. He was at school in Warsaw, and studied literature, history, and philology at the university there, but left, without taking a degree, in 1871. He had begun to publish critical articles showing "positivist" influence in 1869. His first novel, *Na marne* (trans. as *In Vain*, 1889), appeared in 1872, and his first short story, *Stary sługa* (*An Old Retainer*), in 1875. Much of his early work treats social problems in the positivist manner. He traveled in the United States (1876–78) as special correspondent of the *Gazeta polska*, and after his return to Poland, via Italy and France, published successful short stories, among them *Janko Muzykant* (1879; *Yanko the Musician*), *Latarnik* (*The Lighthouse-Keeper*), and *Bartek Zwycięzca* (*Bartek the Conqueror;* both 1882). From 1882 to 1887 he was co-editor of the daily *Słowo*. In 1891 he made a hunting trip to East Africa, described in *Listy z Afriki* (1892).

In 1900, to celebrate the 30th year of his career as a writer, he was presented by the Polish people with the small estate of Oblegorek, near Kielce, where he lived until 1914. Revered in Poland, especially after the award of the Nobel Prize "for his outstanding contribution to the prose epic," and well known abroad, he assumed the role of unofficial spokesman for his countrymen on political issues. In World War I he promoted the cause of Polish independence and organized relief for Polish war victims. He died at Vevey, Switzerland, on Nov. 15, 1916.

Sienkiewicz' great historical trilogy, which began to appear in *Słowo* in 1883, was written "to fortify the hearts of his countrymen." It comprises *Ogniem i mieczem* (four volumes, 1884; *With Fire and Sword*, 1885); *Potop* (six volumes, 1886; *The Deluge*, two volumes, 1895); and *Pan Wołodyjowski* (three volumes, 1887–88; *Pan Michael*, 1895). Set in the later 17th century, it describes Poland's struggles against Cossacks, Tatars, Swedes, and Turks, stressing Polish heroism in a vivid style of epic clarity and simplicity. Although historians deplore its lack of historical accuracy, literary critics praise its narrative power, even when they condemn its theatricality. Stylistically it is of great interest for its artistic re-creation of 17th-century language.

The most famous of Sienkiewicz' other novels is the widely translated *Quo Vadis* (three volumes, 1896; English translation 1898), a historical novel of Rome under Nero. *Bez dogmatu* (three volumes, 1891; *Without Dogma*, 1893) is a penetrating, though overlong, psychological novel; *Rodzina Połanieckich* (1893–94; three volumes, 1895; *Children of the Soil*, 1895) is a didactic *roman de moeurs*. Other works include the medieval historical novel *Krzyżacy* (four volumes, 1900; *The Teutonic Knights*, 1943) and *W pustyni i w puszczy* (1911; *In Desert and Wilderness*, 1912; reprinted 1945), a story for children.

BIBLIOGRAPHY.—The definitive edition of Sienkiewicz' works is *Pisma*, by J. Krzyżanowski, with biographical material and bibliography, 60 vol. (1948–60). English translations include *Yanko the Musician and Other Stories* (1893); *Tales from H. Sienkiewicz* (1931); *Portrait of America: Letters of H. Sienkiewicz*, ed. and trans. by C. Morley (1959). *See* also K. Czachowski, *H. Sienkiewicz, Obraz twórczości* (1931); J. Birkenmajer, "H. Sienkiewicz," in *Thought*, XIV (1939); W. Lednicki, *Henryk Sienkiewicz* (1960). (L. R. LR.)

SIERRA LEONE, an independent sovereign state in West Africa and a member of the Commonwealth of Nations, is bounded north and east by the Republic of Guinea, south by Liberia, and west by the Atlantic Ocean. Area 27,925 sq.mi. (72,326 sq.km.). Before achieving independence in 1961, Sierra Leone was divided into two parts, a British colony and protectorate. The area of the former colony is wholly coastal, consisting of the Sierra Leone Peninsula, at the northern end of which stands the capital and chief port, Freetown; Sherbro and smaller islands, with the town of Bonthe; and Turner's Peninsula. The former protectorate included the headwaters of the Niger River, which flows northeast, away from the Atlantic, eventually reaching the Gulf of Guinea in Nigeria.

PHYSICAL GEOGRAPHY

Relief and Drainage.—The mountains of the Sierra Leone Peninsula, consisting of igneous (norite) rocks, run parallel to the sea for about 25 mi. (40 km.) with a maximum width of 12 mi. (19 km.) and reach 2,912 ft. (888 m.) in Picket Hill. They are well watered, thickly wooded, and much dissected by deeply cut ravines. The name Sierra Leone derives from that given to the range by the Portuguese explorer Pedro da Cintra in 1462. Along the Atlantic coast there extends a flat, low-lying, and frequently flooded coastal plain, 20–40 mi. (32–64 km.) wide and composed of sands and clays. The numerous estuaries are fringed below high-tide mark by extensive mangrove swamps. In the south the plain gives way inland to rolling wooded country with isolated hills rising to more than 1,000 ft. (300 m.). In the north the plain is backed by an upland plateau reaching to 1,500 ft. or more. The plateau is principally composed of granite, but to the west it is bounded by a narrow outcrop of metamorphic rocks, the Kambui schists, in which valuable metal ores, including gold, iron, and chromite occur. Above the plateau surface rise several mountain ranges, reaching 6,390 ft. (1,948 m.) in Bintimane (Loma Mountains) and 6,080 ft. (1,853 m.) in Sankan Biriwa (Tingi Hills).

Numerous rivers rise in the well-watered Fouta Djallon Plateau and flow down its steep slopes southwest to the Atlantic Ocean. Their middle courses are interrupted by rapids, but they are navigable in parts and those in the south are important for the commercial movement of goods. From north to south the principal rivers are: the Great Scarcies (or Kolenté), Sierra Leone's northwestern boundary with the Republic of Guinea; Little Scarcies (Kaba); Rokel (Seli), known in its lower course as the Sierra Leone River, with the large, sheltered harbour of Freetown at its mouth; Jong (Teye); Sewa (Bum); Waanje; Moa; and Mano (Moro), forming the country's boundary with Liberia.

Climate.—Conditions are generally hot, with average tempera-

tures of 24°–29° C (75°–85° F) on the coast and between 20.5° and 35° C (69° and 95° F) in the interior, and, during the rains (May–October), very wet. During the dry season (November–April) the harmattan wind from the northeast frequently blows, bringing with it fine Saharan dust, poor visibility, and very low relative humidity. The rainy season is introduced by a series of squalls with thunder and lightning.

Relative humidity during the rains may be as high as 90% for considerable periods, particularly during the wettest months, July to September. Annual average rainfall totals range from more than 150 in. (3,810 mm.) in the peninsula mountains to 80 in. (2,032 mm.) in the north. Freetown (128 in. [3,251 mm.]) recorded 13.40 in. (340 mm.) in one day in July 1948 and 5.91 in. (152 mm.) in an hour in September 1944.

Sierra Leone was formerly known as "the white man's grave," but during the 20th century living and health conditions greatly improved.

PRINCIPAL PHYSICAL FEATURES, TOWNS, AND RAILWAYS OF SIERRA LEONE

Vegetation.—Forest probably covered most of Sierra Leone in the past, but has been greatly reduced in area, particularly through felling for cultivation. The wetter areas are still forest-covered, especially where forest reserves have been constituted, as on the hills of the peninsula and in the Gola Forest near the Liberian border, but savanna woodland (sometimes known as orchard bush) and grassland are increasingly common. Valuable timber trees exploited include species of *Khaya* (African mahogany) and African teak (*Oldfieldia africana*).

In the interior there is much secondary forest, where trees have at some past time been felled to permit cultivation; in these areas the African oil palm (*Elaeis guineensis*) is often common and has great economic value as a source of palm oil and palm kernels. Where the annual rainfall decreases, savanna grassland or woodland with fire-tolerant trees, such as lophira, become increasingly common. Grassland has developed throughout the country where the soils are too thin or the slopes too steep for tree growth and is particularly characteristic on lateritic patches. Swamps, which flood seasonally, abound along the beds of streams, and mangroves flourish in the saline tidal areas of river estuaries, though they are being drained and cleared in places for the cultivation of swamp rice. The swamps of the southern coastlands are important producers of the fibre piassava, used in the manufacture of strong brooms and obtained from the swamp palms *Raphia vinifera* and *R. gaertneri*.

Animal Life.—The relatively few large game animals are rarely seen because of the density of the vegetation; they include elephant, leopard, bush cow or dwarf buffalo (*Syncerus nanus*), and antelope (including duiker, the harnessed antelope, and, in the Gola Forest, the bongo). Tiger cats, civets, chimpanzees, various species of monkey, porcupines, bush pigs, and cane rats (also called "cutting grass") are common. Some of these are responsible for much damage to growing crops. During the dry season lions occasionally come in from Guinea in search of game. Birds and insects abound, the latter including mosquitoes, tsetse flies, termites, locusts, and sand flies. Hippopotamuses, both normal and pygmy, crocodiles, and manatees are common in the rivers, and the estuaries are often shark-infested. Fish, caught both in the rivers and at sea, include tarpon, barracuda, mullet, and "bonga" (a species of shad). The coastal waters off Sierra Leone constitute an excellent fishing ground, which is as yet not fully exploited. (R. W. SL.)

THE PEOPLE

The Mende (*q.v.*), Loko, Kono, Vai (*q.v.*), Koranko, Susu (*q.v.*), and Yalunka peoples belong to the Mande linguistic group (*see* MANDINGO), and the Temne (*q.v.*), Limba, and Bulom to the semi-Bantu group. The tribes have many cultural features in common, from long association with the Muslim Fulani and Mandingo, the dominating influence of the two largest tribes (Mende and Temne), and contact with Europeans. The Mende in the centre and south, and the Temne in the north, divide into 60 and 44 chiefdoms respectively, each ruled by a paramount chief and a council of section chiefs. The main economic activity is agriculture; in most areas rice is the staple crop, but the Bulom grow cassava and fishing is important among them. Descent is normally patrilineal, although there are close links with certain maternal relatives. The Temne divide into 25 patriclans. The Poro and Sande secret societies (for men and women respectively) sanction behaviour in most aspects of life; the Temne have the Ragbenle Society in addition. The population in the former colony area also includes Creoles, the descendants of repatriated slaves mainly from Nova Scotia and the West Indies.

The only lingua franca is a form of pidgin English which is

fairly widespread, though by no means universal. There are diverse animist beliefs, rites, and practices among tribes and families. Islam is followed in parts of Sierra Leone, and Christianity is well established. Freetown is the seat of the Roman Catholic bishop of Freetown and Bo, and of the Anglican archbishop of West Africa. (ME. F.)

Population and Towns.—According to the census of April 1963 the population was 2,180,355. Freetown (*q.v.*) is the capital and chief port, but iron ore is shipped from Pepel, a short distance up the Sierra Leone River. The other chief towns are Bo (the former capital of the protectorate) in Southern Province, the diamond-mining centre of Kenema in Eastern Province, and the trading centre of Makeni in Northern Province. Lunsar, near the Marampa iron mines, grew rapidly in the 1950s. Other important settlements are Waterloo, a Creole town on the peninsula; Kabala in Northern Province; and Kambia in the Scarcies River rice district. (R. L.)

HISTORY

Sierra Leone was originally divided into many small independent kingdoms or chiefdoms; each had its own ruler whose power was checked by his council of subchiefs. In many areas there were also secret societies, of which the Poro Society is the best known, which maintained law and order as well as instructing initiates in the traditions and customs of the country (*see* SECRET SOCIETIES, PRIMITIVE). The Bulom people have been settled immemorially on the coast. The Temne, by tradition migrants from the north, were well established on the coast by the 15th century. The Mende reached it only by slow migration in the 19th century.

Portuguese voyagers gave the name Serra Lyoa ("Lion Mountain"), later corrupted to Sierra Leone, to the mountainous peninsula at the mouth of the Rokel River. From the late 15th century European ships of all nationalities put in regularly, near the site where Freetown now stands, to take on water and firewood and to trade manufactured goods for slaves and ivory. Though English trading posts were built on Bunce and York islands in the 17th century, no European power exercised jurisdiction in Sierra Leone. Traders settled there under the protection of the African rulers, who welcomed them for the goods they brought. In the early 18th century the Fulani and Mandingo Muslim peoples in Fouta Djallon (Futa Jalon), north of Sierra Leone (later in Guinea), started a holy war of conversion. From Fouta Djallon, Islam spread gradually to the coast. By the end of the 19th century it was firmly established in northern Sierra Leone and in the 20th century began to spread among the Mende.

A group of freed slaves of African birth or origin arrived in Sierra Leone from England to form a settlement in 1787. Its sponsor, the English slave abolitionist Granville Sharp, called it "the Province of Freedom" and hoped it would become a base against the slave trade. King Tom, a Temne subchief, gave the colonists a strip of land, but his successor, King Jimmy, drove them away in 1789. The settlement was revived in 1791 by the Sierra Leone Company, a trading company sponsored by opponents of the slave trade, with headquarters in London. The town was rebuilt and named Freetown. The company brought from Nova Scotia, as settlers, some former slaves who had gained their freedom by serving the British in the American Revolutionary War. They were joined in 1800 by "Maroons," free Negroes from the mountains of Jamaica, who had been deported to Nova Scotia for insurrection. These settlers, African in origin, were English-speaking and many were literate and Christian.

After the British Parliament made the slave trade illegal in 1807, the British government took over the settlement (Jan. 1, 1808) as a naval base against the slave trade and as a centre to which slaves, captured in transit across the Atlantic, could be brought and freed. Between 1807 and 1864, when the last slave ship case was adjudicated in the Freetown courts, the British Navy brought in more than 50,000 "recaptives." Drawn from all over West Africa, these heterogeneous people lacked any common language or culture. Inspired by Sir Charles MacCarthy, governor from 1814 to 1824, the government undertook a deliberate policy of turning them into a homogeneous, Christian community. Missionaries of the (Anglican) Church Missionary Society (CMS) and the Methodist Missionary Society, and the pastors of the Freetown settler churches, worked among them with such success that within a generation the policy was virtually fulfilled. The CMS, as well as opening boys' and girls' secondary schools, founded an institution at Fourah Bay, near Freetown, to train teachers and missionaries (see *Education, Welfare, and Defense* below).

The recaptives and their children (known as Creoles) prospered as traders, opening stores or bartering imported European goods in the neighbourhood for exportable palm produce. Many left the colony to trade along the coast or to work there as clerks, teachers, or missionaries. At their suggestion, English missions were started in the Yoruba country (later part of Nigeria), the homeland of many recaptives. Thus they formed an educated West African elite, bringing to their homeland the new ways they had learned.

The most famous recaptive was Samuel Adjai Crowther, who became an Anglican priest in 1843 and bishop in the Niger territories in 1864. Among distinguished Creoles were Africanus Horton and William Davies, who qualified in Britain in 1859 as doctors and served as officers in the British Army; and Samuel Lewis, a barrister, who served many years on the colony's Legislative Council and was knighted in 1896.

Colony and Protectorate.—The colony made treaties of friendship with most of the neighbouring chiefs and gradually acquired jurisdiction over the adjoining coastline. The Creoles wanted to extend the colony inland, but the British government was unwilling to accept new West African responsibilities. By 1890, however, it was realized in London that the French, rapidly advancing inland, would soon hem the colony into a tiny enclave and destroy Freetown's value as a naval base. A more expansive policy was sanctioned, frontiers were delimited with the French and Liberian governments, and a British protectorate was proclaimed in 1896 over the area within the frontier lines. The British government made no contribution toward governing the new protectorate so Sir Frederic Cardew, governor from 1894 to 1900, introduced a hut tax to raise extra revenue to pay for the enlarged administration. The chiefs, who had not been consulted about the protectorate, objected. A revolt broke out in the north in 1898 under an experienced war chief, Bai Bureh. It spread among the Mende but was suppressed by the end of the year. There was no further armed rising against the British.

The protectorate was governed on the principles of indirect rule, afterward introduced by Frederick (later Lord) Lugard into Nigeria. The chiefs retained much of their power, under the supervision of British district commissioners. Traditional ways were encouraged, and for the first decades of the 20th century little was done to extend education in the protectorate. During the 19th century many Creoles held senior official posts and looked forward to governing themselves ultimately. But after the protectorate was assumed they were gradually removed from office and both colony and protectorate were ruled by British administrators. A new constitution in 1924 allowed a few Creoles to be elected, and protectorate chiefs nominated, to the Legislative Council, but this did not satisfy nationalist aspirations.

Independence.—After World War II British policy changed in Sierra Leone, as elsewhere in West Africa, it was agreed to constitute democratic institutions through which the dependent territories could evolve into independent states. The small educated minority of Creoles hoped to entrench themselves politically, lest under a fully democratic constitution they should be overwhelmed by the protectorate peoples. But the 1951 constitution gave power to the majority. The government elected under it was led by Milton (later Sir Milton) Margai, a physician and leader of the Sierra Leone People's Party (SLPP), a predominantly protectorate party.

During the 1950s parliamentary institutions on the British pattern were introduced in successive stages. In 1956 the Legislative Council was renamed the House of Representatives; in 1957 elections were held with direct voting, women being eligible to vote; in 1958 the ex officio members left the legislature, and in 1960 the governor gave up his reserved powers. The last stage was reached on April 27, 1961, when Sierra Leone became an indepen-

Hospital beds in establishments conducted by the government, missions, and mining companies exceeded 1,500, and there were in addition about 90 government dispensaries and health centres, as well as treatment centres attached to the Endemic Diseases Control Unit.

Wages and conditions of employment are regulated by joint industrial councils and wages boards. By the mid-1960s there were a number of registered labour unions, including mineworkers, railway workers, and maritime and waterfront workers.

The Royal Sierra Leone Military Force comprises one battalion, supporting services, and a volunteer naval force.

dent state within the Commonwealth. The governor, Sir Maurice Dorman, elevated to the position of governor general, was succeeded in 1962 by a Sierra Leonean, Sir Henry Lightfoot Boston.

Though the SLPP formed an alliance in 1960 with some of the rival political groups, a vigorous opposition party, the All People's Congress, emerged, and during the early years of independence Sierra Leone remained a two-party state. In 1964 Sir Milton Margai died and was succeeded as prime minister by his brother, formerly the finance minister, Sir Albert Margai. (C. Fy.)

ADMINISTRATION AND SOCIAL CONDITIONS

Administration.—The constitution provides for a governor general appointed by the British sovereign on the advice of the Sierra Leone prime minister; for a House of Representatives of not fewer than 60 members and a normal life of five years; for universal adult suffrage; and for executive responsibility by a cabinet of ministers appointed by the prime minister and presided over by him. There are a Supreme Court and a Court of Appeal, with further appeal to the Judicial Committee of the British Privy Council in certain cases. The chief justice is appointed by the governor general on the advice of the prime minister; other judges are appointed on the advice of the Judicial Service Commission. The constitution includes the customary provisions governing citizenship and safeguarding individual rights and freedoms.

Outside the Freetown Peninsula (or Western Area) the country is divided for purposes of local administration into the Southern, Eastern, and Northern provinces, which are subdivided into districts. Sierra Leone's 146 chiefdoms form the basic unit of local government; in each chiefdom the tribal authorities elect a paramount chief who sits in the District Council with the elected members of the council.

Education, Welfare, and Defense.—The chief institution of higher education is the University College of Sierra Leone, a reconstitution (1960) of Fourah Bay College, founded at Leicester near Freetown by the Church Missionary Society in 1827. In 1876 it was affiliated to Durham University, in England, and in the 1950s moved to Mt. Aureol overlooking Freetown. It has about 550 students. Another university college, specializing in agricultural education, was opened at Njala in 1965. Illiteracy is still widespread, but by the mid-1960s there were more than 800 primary schools with about 135,000 pupils; more than 50 secondary schools (with about 13,500 pupils); 6 teacher-training colleges, and 2 technical institutes (Freetown and Kenema).

THE ECONOMY

Although since the 1930s minerals have been of increasing importance, Sierra Leone still has a subsistence economy based on rice growing on the upland slopes or in the swamps and estuaries.

Agriculture.—Agriculture occupies about 80% of the population. Besides rice, the main food crops are palm oil and cassava. The chief export crops are palm kernels (about 60,000 tons annually), cocoa (4,000 tons), coffee of the species *Coffea robusta* (4,500 tons), and piassava brush fibre (5,000 tons). Cultivation, transport, and marketing are assisted by cooperatives and by marketing and credit societies. Market gardening is carried on around Freetown and in Northern Province around Kabala in the Koinadugu District. Koinadugu District is also the centre of the livestock industry.

Mining.—Iron ore (about 2,000,000 tons annually) is extracted from strip mines at Marampa; deposits of rutile and bauxite exist near the coast in Southern Province. Diamonds, the country's most valuable product, were first found in river gravels of the Kono District, about 140 mi. (225 km.) E of Freetown. Subsequent prospecting revealed diamond-bearing deposits over much of the Bafi-Sewa River system. In 1935 a British company obtained a 99-year concession covering the whole country. Following World War II, local poverty combined with boom prices for diamonds encouraged illicit mining, which was carried on not only by the inhabitants but also by thousands of immigrants (largely from French Guinea) and organized by the Lebanese community. The company's monopoly was rescinded in 1955 except for 450 sq.mi. (1,165 sq.km.) around Yengema in Eastern Province. The government thereafter opened up the surrendered area to licensed Sierra Leonean diggers and in 1959 established its own buying office. By these measures, illegal exports of diamonds were materially reduced. The Sierra Leone deposits lie in gravel layers up to four feet thick beneath a shallow alluvial covering and half the diamonds they yield are gem stones. The concessionary company produces between one-quarter and one-third of the total output; during the dry season about 3,300 licensed diggers are at work. The value of diamond exports in 1964 was nearly £20,000,000.

Industry and Power.—The main industries are concerned with processing agricultural and forest products (oil mills, rice mills, sawmills). Furniture, cigarettes, soft drinks, nails, and oxygen and other compressed gases are produced locally. Further industrial development depends chiefly on power supplies. By the mid-1960s the generating capacity in Freetown was about 10,000 kw., and there were about 20 small power stations in the provinces. Fishing is important, and village industries include fish curing and smoking, hand-expressing of palm oil, and cracking palm kernels.

Trade and Finance.—Sierra Leonean overseas trade expanded substantially in the 1950s. More than 50% of imports come from other Commonwealth countries (the bulk from the U.K.); the main imports are foodstuffs, cotton fabrics, clothing and footwear, machinery, motor vehicles, petroleum products, and tobacco. Minerals account for about 70% of total exports by value, agricultural products for about 16%; most of the exports go to the U.K.

The unit of currency is the leone (1 leone = 10*s*. sterling = $1.40 U.S.), divided into 100 cents, which is replacing the West African shilling.

Transport and Communications.—A state-owned railway of 2 ft. 6 in. gauge runs east from Freetown to Pendembu (227.5 mi. [366 km.]) near the Liberian frontier. A branch line from Bauya runs northeast to Makeni. The railway has many difficult gradients and limited carrying capacity and has never covered its capital costs. An iron-ore railway of 3 ft. 6 in. gauge joins Marampa with Pepel. Inland waterways total about 500 mi. (800 km.) and there is a considerable volume of river traffic, carried by launches, including coastwise routes from Freetown southward to Bonthe and northward on the Great and Little Scarcies rivers. Freetown, the finest natural harbour in Africa, is a regular port of call for numerous shipping lines and can accommodate large ships alongside the Queen Elizabeth II Wharf, opened in 1954. The international airport of Lungi is on the north bank of the Sierra Leone River opposite Freetown, but domestic air services use the smaller Hastings Airfield at Freetown. The principal towns are accessible by road and the majority of villages can be reached by truck; in the mid-1960s the system comprised about 2,175 mi. (3,500 km.) of main roads and 2,200 mi. (3,540 km.) of secondary roads.

The Sierra Leone Broadcasting Service (founded 1934) transmits in English and a number of indigenous languages.

Current history and statistics are summarized annually in the *Britannica Book of the Year*.

SIERRA MORENA, Spain, forms the mountainous southern edge of the Meseta (plateau), stretching for about 200 mi. (320 km.) from the Sierra de Alcaraz (5,899 ft. [1,798 m.]) in the east to the Portuguese border in the west. It includes many minor ranges which run transversely: *e.g.*, the Sierra Madrona, Sierra de Almadén, and Sierra de Aracena. It forms the main watershed between the rivers Guadiana and Guadalquivir, and its southern edge, overlooking the plains of Andalusia, is marked by a fault line; streams flowing south to join the Guadalquivir have eroded deep valleys in the scarp face, which descends from more than 1,500 ft. (450 m.) to land below 300 ft. (90 m.). Most of the Sierra Morena is wild desolate country thickly covered with dense evergreen bushes and shrubs. Its great breadth has long made it a formidable barrier in the social and military history of Spain. The chief communications route is via the Puerto de Despeñaperros which links Andalusia with Castile. The geological structure is very complex, exhibiting faulting and associated metamorphism resulting in the formation of minerals. Silver, lead, and copper are mined in the region of Linares; mercury at Almadén; copper at Ríotinto and at Tharsis in the Sierra de Aracena.

(J. M. Ho.)

SIERRA NEVADA, a range of mountains in southeast Spain. It is the highest range in the Baetic Cordillera (*see* PENIBÉTICO, SISTEMA), sometimes known as the Sierra Nevada system. The Nevada itself is clearly defined by the faulted troughs of the Vega of Granada to the northwest, the Guadix tableland to the northeast, and the Alpujarras (*q.v.*) depression to the south. The Nevada is a domed mountain elongated for about 26 mi. (41 km.) from east to west. The central dome, composed of hard slates (*lastra*) and softer micaceous schists presenting a smooth skyline, has been faulted so that the northern slopes rise precipitously, while the south and southeast flanks are gentler. On the edges of the centrally breached anticline are situated the main peaks: the Cerro de Mulhacén (11,411 ft. [3,478 m.]), the highest point of the Iberian Peninsula, and the Picacho de Veleta (11,128 ft. [3,392 m.]). Several other summits rise above the snowline, which lies at 10,000 ft. (3,050 m.), and have given significance to its name "the snowy range." Partly glaciated during the Würm period, leaving a trail of moraines and cirques, there is still a minute glacier in the Corral de Veleta. The range lies only a few miles inland from the Mediterranean coast and rises to above 10,000 ft.; the combination of Mediterranean climate and height has produced a sequence of flora from subtropical to alpine species.

(J. M. Ho.)

SIERRA NEVADA (Spanish, "Snowy Mountains"), of California, one of the major ranges of the United States, extends from Tehachapi Pass north-northwestward 400 mi. to Lake Almanor. Its breadth varies from 40 to 80 mi. The highest peak is Mt. Whitney, 14,495 ft.

The range consists chiefly of granite, flanked in places by belts of metamorphosed sediments, and overlain elsewhere by Tertiary volcanic materials. The range was created by block faulting: this great section of the earth's crust was broken apart from its surroundings, raised and tilted into a new position. The eastern edge became a massive escarpment, towering nearly three miles above Owens Valley. Streams cut deep valleys into the gentle western slope and deposited the resultant detritus onto the depressed western portion, creating the vast alluvial plains of the San Joaquin-Sacramento Valley ("Great Valley"). During the Pleistocene Epoch alpine glaciers reshaped some valleys, creating the spectacular scenery of Yosemite Valley and producing peaks, pinnacles, and rock-rimmed lakes along the eastern crest. In a few high sheltered valleys, small glaciers still remain.

This massive, unbroken barrier lifts the prevailing winds moving eastward off the Pacific Ocean, producing heavy precipitation, especially in winter, on the western slope (30–40 ft. of snowfall at 6,000 ft. in an average winter) and creating a desert eastward into Nevada. The range is a vast reservoir for water, supplying irrigation requirements for the Great Valley and municipal requirements for several cities, notably San Francisco and Los Angeles.

The great differences in altitude produce marked contrasts in vegetation. On the west, the grasslands of the Great Valley are succeeded upslope by a belt of oak woodland, replaced in turn by chaparral (drought-resistant dense brush), yellow pine forest, white fir–red fir forest, lodgepole pine forest, subalpine forest, and culminating finally in alpine meadows and bare rock slopes above the timberline. On certain unglaciated interfluves amidst the yellow pine forests are groves of Sequoias (*Sequoia gigantea* "big tree"), world renowned for their great age and size. On the steep eastern slope the transition from forest to desert is abrupt. Some lumbering is carried on in the west-slope forests. The upper zones are grazed by sheep in summer and the foothills support cattle through the year.

Gold was discovered in 1848 in Sacramento Valley gravels derived from the Sierra Nevada. Soon, thereafter, the bedrock source or "mother lode" was discovered on the western slope. After a wild period of mining booms and a longer period of steady production, mining activity gradually declined and the old mining towns became more important as tourist attractions than as mineral producers.

Tourists also visit the Sierra Nevada mountain recreation centres in great numbers in both summer and midwinter. Among the chief attractions are the three national parks—Yosemite, Sequoia and Kings Canyon (*qq.v.*)—and several ski centres in the national parks, the Donner Pass-Tahoe-Reno region, and the Mammoth area on the eastern slope.

Donner Pass (7,017 ft.), used by the Southern Pacific Railroad and highway U.S. 40, is the most important transmontane route, connecting San Francisco with Reno, Nev. Farther south, the mountains constitute an almost impenetrable barrier to land trans-

portation: from Tioga Pass to Walker Pass, a distance of 165 mi., no road crosses the range.

Aside from scattered recreation areas, lumber camps, and small towns serving the transmontane transportation routes, the Sierra Nevada range is virtually devoid of permanent inhabitants. Much of it is included in the national parks and several national forests.

SIEYÈS, EMMANUEL JOSEPH (1748–1836), French abbé and statesman who was one of the chief theorists of the French Revolution and an architect of the coup that replaced the Directory by the Consulate. He was born at Fréjus, in Provence, on May 3, 1748. Sent to the Sorbonne in Paris to be educated for an ecclesiastical career, he took less interest in theology than in the teachings of Locke, Condillac, and other political philosophers but nevertheless entered the church. He rose to be vicar-general (1780) and chancellor (1788) of the diocese of Chartres.

In January 1789, after the summoning of the Estates-General for the following May (*see* FRANCE: *History*), Sieyès published his pamphlet *Qu'est-ce que le Tiers État?* ("What Is the Third Estate?"). He began his answer thus: "Everything. What has it been hitherto in the political order? Nothing. What does it desire? To be something." The pamphlet had a great vogue, and its author was elected as the last of the 20 Paris deputies of the Third Estate. He strongly advised that the Estates-General meet in one chamber as the National Assembly, but he objected to the abolition of tithes and the confiscation of church lands without compensatory payment. He supported individual rights and civil equality, but not absolute political equality. Wishing to keep real power in the hands of the enlightened *bourgeoisie*, he resisted the idea of referendum and "imperative mandate": on the contrary, he thought that representatives elected for a specified period should be free to vote as they might see fit. In the committee on the constitution he argued against allowing the king to have a right of veto. He had a considerable part in the framing of the system of *départements*, but after the spring of 1790 he was eclipsed by men of more determined character and more revolutionary aims. Only once (June 1790) was he elected to the post of fortnightly president of the Constituent Assembly.

Ineligible for the Legislative Assembly of 1791 (as was every member of the Constituent Assembly), Sieyès was elected to the National Convention by three *départements* (Gironde, Orne, Sarthe) in September 1792. In the Convention he sat with the centre. He voted for the death sentence on Louis XVI. Soon afterward he effaced himself step by step, partly from disgust, partly from timidity. He abjured the Christian faith when the cult of Reason was instituted. It is said that he later summarized his conduct during the Terror in the ironical phrase *"J'ai vécu"* ("I remained alive").

After the fall of Robespierre (July 1794), Sieyès became more active. In 1795 he was on the Committee of Public Safety for six months, concerning himself with foreign policy; and his mission to The Hague was followed by a peace treaty with the Dutch and by France's alliance with the new Batavian Republic. He tried in vain to ensure that the new French Constitution of the Year III (1795) should establish a "constitutionary jury" with power to annul unconstitutional laws. Elected to the Council of the Five Hundred in October 1795, he was then voted a member of the Directory by the Chambers but declined to serve in this latter post. In May 1798 he was sent to Berlin to induce Prussia to make common cause with France; but though he negotiated adroitly he failed in his main object.

Sieyès was elected a director in place of J. F. Reubell in May 1799. He was already contemplating the overthrow of the Constitution, which was supposed to remain in force for six years from 1795 before it could be revised. To promote his plans he relied on the moderate republicans, took action against the Jacobins, and made overtures to Gen. B. C. Joubert for a *coup d'état*. Joubert's death and Napoleon Bonaparte's return from Egypt blocked his schemes; he then managed to come to an understanding with Bonaparte. On 19 Brumaire (Nov. 10, 1799) he became a provisional consul with Bonaparte and P. R. Ducos. His proposals for the Constitution of the Year VIII (Dec. 25, 1799) were characterized by his desire to maintain an oligarchy of men who had emerged in the original period of the Revolution: he wanted the political assemblies to be composed of members co-opted rather than directly elected by the citizens; and he believed that a chamber consisting of life members should have power to annul unconstitutional laws. Bonaparte accepted these two points but secured the rejection of the complex system proposed by Sieyès for balancing powers and for preventing the supremacy of any one man. Sieyès declined the title of second consul; he became the first member of the Senate and played a leading part in the first recruitment of senators, legislators, and tribunes.

From 1800 to 1802 Sieyès may have given secret encouragement to opposition groups. Thereafter he played a progressively diminishing role. He was nominated grand officer of the Legion of Honour in 1804 and a count of the empire (together with all the other senators) in 1808. Though he was one of the senators who voted against Napoleon in April 1814, he accepted a seat in the Chamber of Peers during the Hundred Days (1815). Banished at the Second Restoration, he went to Brussels. After the revolution of 1830 he returned to France and died in Paris on June 20, 1836.

During the Revolutionary period Sieyès enjoyed great fame as a political theorist, but his pride soon made him enemies, and his feeble voice and lack of oratorical power reduced his direct influence on large audiences. His prudence moreover led him to prefer to act indirectly save in 1799. In political conflict he was keen-sighted, resilient, and practical; but with regard to institutions he was dogmatic and uncompromising. Thus he had more influence on political doctrine than on any actual constitutional system.

SIGEBERT, the name of three Frankish kings of the Merovingian dynasty.

SIGEBERT I (d. 575), king of the region afterward known as Austrasia, was the third son of Clotaire I and Queen Ingund. In the division made at his father's death (561), he received the northeastern part of the kingdom. To this was added, at the death (567) of his eldest brother Charibert, lands south of the Garonne and a large area in the west, including Touraine and Poitou. Menaced by the Avars (established in Germany since 558), he moved his capital from Reims to Metz and had twice to repel their attacks (562 and *c.* 568). He married (567) Brunhilda (*q.v.*), daughter of the Visigothic king Athanagild, whose other daughter Galswintha married Sigebert's half-brother Chilperic I. When Chilperic had Galswintha murdered (567 or 568) in order to marry his mistress Fredegund, Sigebert in revenge exacted from Chilperic his sister-in-law's dowry (Bordeaux, Limoges, Quercy, Béarn, and Bigorre). Prolonged warfare followed, during which Sigebert twice sought help from barbarian tribes beyond the Rhine. They ravaged the Paris area in 575, and Chilperic fled to Tournai. Sigebert, now controlling all the territory between the Loire and the Seine, pursued him. At his moment of triumph, when he was on the point of being acclaimed king at Vitry by Chilperic's subjects, he was stabbed by two assassins sent by Fredegund (early December 575).

SIGEBERT II (601–613), eldest of the four sons of Theuderic II, "reigned" only a few months and was never acclaimed king. On his father's death (613), his great-grandmother Brunhilda proposed his succession, but the Austrasian aristocracy rebelled and sought help from Clotaire II of Neustria. Brunhilda's army refused to fight that of Clotaire, and Theuderic's children fell into Clotaire's hands. Sigebert and one of his brothers were killed, a third died later at Clotaire's court, and the fourth disappeared.

SIGEBERT III (II) (630/631–656), was king of Austrasia under his father Dagobert I (*q.v.*) from 633 or 634, and sole king from

639. To conciliate the Austrasians, resentful that Dagobert had moved his residence from Metz to Paris, the three-year-old Sigebert was established at Metz (633 or 634) with a household ruled by Chunibert, bishop of Cologne, and the duke Adalgisile. On Dagobert's death (January 639), Pepin the Old (d. *c.* 640; *see* CAROLINGIANS) regained his influence in Austrasia, where he had been mayor of the palace before Dagobert's accession. By 643 Pepin's son Grimoald was mayor of the palace and Sigebert was thereafter completely under his tutelage. Before the birth of Sigebert's son, the future Dagobert II, Sigebert had adopted Grimoald's son Childebert, whom Grimoald later established as king for a few months (660 or 661). Sigebert died on Feb. 1, 656, and was succeeded by Dagobert II.

SIGER OF BRABANT (d. between 1281 and 1284), professor of philosophy at Paris and leader of heterodox Aristotelianism, was a native of the duchy of Brabant. From 1266 (when his name first appears) to 1276 he was prominent in the dissensions that troubled the faculty of arts in Paris. From his earliest years as a teacher he professed a disquieting Aristotelianism, without regard for orthodox Christian doctrine. His teaching was attacked by Bonaventura, the minister general of the Friars Minor, and by Thomas Aquinas, the head of the Dominican school. On Dec. 10, 1270, Étienne Tempier, bishop of Paris, condemned 13 errors taken from the teaching of Siger and his partisans. On Nov. 23, 1276, the inquisitor of France summoned Siger, Goswin of the Chapel and Bernier of Nivelles before his tribunal; they fled to Italy and probably appealed to the tribunal of the papal curia. On March 7, 1277, Tempier pronounced the condemnation of 219 propositions, aiming especially at the teaching of Siger and Boëtius of Dacia. Siger was probably condemned to stay at the curia in the company of a cleric; he was stabbed at Orvieto, by his cleric, who had gone mad, and died under the pontificate of Martin IV, before Nov. 10, 1284. Dante (*Paradise*, x, 133–138) puts Siger in the Heaven of Light in the brilliant company of 12 illustrious souls who are glorified because of their fidelity to their own providential mission: Siger fought all his life for the autonomy of philosophy.

By the middle of the 20th century 14 certainly authentic works of Siger's and at least 6 probably authentic commentaries on Aristotle were known. The most important are: *Quaestiones in Metaphysicam; Impossibilia* (six exercises in sophistry); *Quaestiones de necessitate et contingentia causarum; Quaestiones in tertium de Anima;* and *Tractatus de anima intellectiva.*

Siger is an important representative of that school of radical Aristotelianism which arose in the faculty of arts at Paris when Latin translations of Greek and Arabic works had led to the discovery of philosophy by the masters there. Some of these masters, after 1260, inaugurated a purely rational teaching, without any concern with the exigencies of Christian faith; and Siger appears as the leader of this group. His capital source is Aristotle; secondary sources are Proclus and Avicenna (chiefly in metaphysics), Averroes (chiefly in psychology), Albert the Great and Thomas Aquinas. Siger's most typical doctrines are: the First Being is the immediate cause of a single creature, the first intelligence; all other creatures derive indirectly from God, by way of a progressive emanation; there is no real distinction between essence and existence in creatures; the created world is necessary and eternal, and every species of being (mankind, for instance) is eternal; there is only one intellectual soul for mankind and consequently one will; this unique soul is eternal, but the human individuals are not immortal (on the question of the soul, however, Siger's teaching was not consistent); human will is a passive potency moved by the intellect. Siger never accepted the theory of a double truth (one of reason and one of faith). To characterize his philosophy as "Latin Averroism" is inaccurate: his system must be called a radical or heterodox Aristotelianism.

SIGERIST, HENRY ERNEST (1891–1957), Swiss medical historian who emphasized the social aspects of medicine, was born on April 7, 1891, in Paris and educated in France, Switzerland, England, and Germany. Combining interest in the humanities with medicine (M.D., Zurich, 1917), in 1925 he became professor of the history of medicine at Leipzig and in 1932 professor and director of the Johns Hopkins University Institute of the History of Medicine, the first American medico-historical research centre. A brilliant teacher and strong proponent of socialized medicine, Sigerist attracted disciples interested in medical history, sociology, and public health. His 27 books and 454 papers range from studies in medieval philology (*Studien und Texte zur frühmittelalterlichen Rezeptliteratur*, 1923) to analyses of American and Soviet medicine (*American Medicine*, 1934; *Socialized Medicine in the Soviet Union*, 1937). Upon retirement in 1947 he undertook a comprehensive *History of Medicine* of which the sections on primitive, archaic, and Greek medicine (vol. i, 1951; vol. ii, 1961) were completed before his death at Pura, Switz., on March 17, 1957. (GE. MI.)

SIGHT, SENSE OF: *see* VISION.

SIGHTS, GUN, are mechanical or optical devices that help the gunner aim his weapon at a target. They range from simple iron sights for small arms weapons to complex "fire control systems" for long-range artillery. To understand their nature and use it is essential first to know something of the behaviour of projectiles during flight.

When a projectile is fired from a gun, its flight path, or trajectory, forms a curve due to the action of the force of gravity and the resistance of the air. The force of gravity causes the trajectory to bend downward. If the projectile is rotating about its longitudinal axis, air resistance will cause it to drift to the right or left, depending upon the direction of rotation. These and other factors affecting the trajectory of a projectile are discussed quantitatively in the article BALLISTICS.

In view of these characteristics of the trajectory, it is obvious that the axis of a gun must be pointed above and to one side of the target to make the projectile hit that target. The process

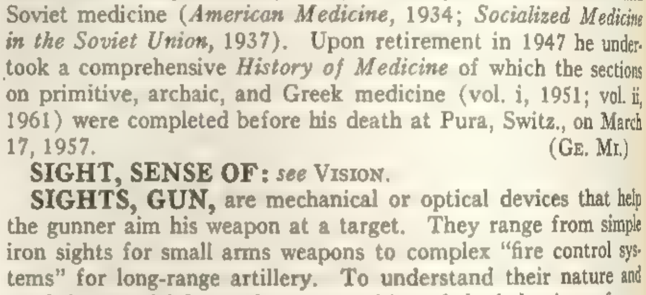

FIG. 1.—SIGHTING TERMS

of pointing a gun in the proper direction and at the desired angle of elevation is known as "laying" the gun. The devices employed to determine the proper direction and elevation for laying the gun constitute the sight or fire control system.

Terminology.—In discussing the principles of sighting, the following terms need to be clearly understood (*see* fig. 1):

Line of Sight.—A straight line joining gun and target.

Angle of Sight.—The angle between the line of sight and the horizontal plane through the gun.

Elevation.—The degree to which the axis of the gun is elevated above some line of reference. Quadrant elevation is the angle between the axis of the gun and the horizontal plane; tangent elevation, or superelevation, is the angle between the axis of the gun and the line of sight.

Rifles and Machine Guns.—The sights used for these types of weapons differ very little throughout the world. They are based on the principle that two points in fixed relation to each other may be brought into line with a third point. A typical rifle sight con-

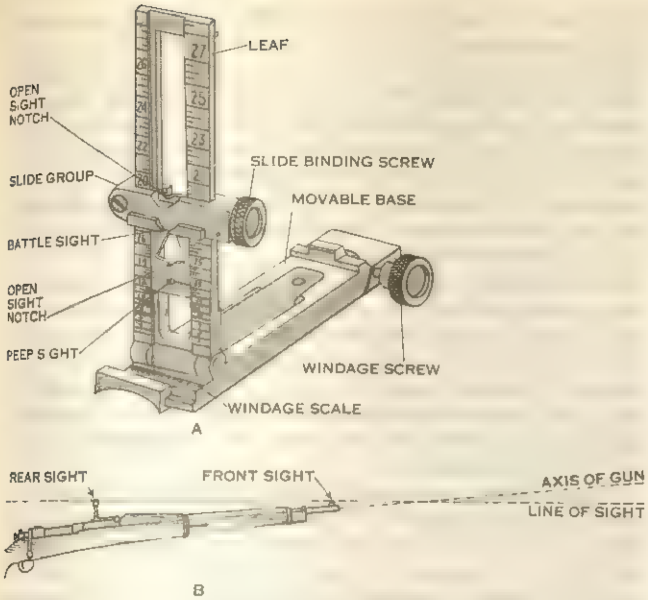

FIG. 2.—RIFLE AND MACHINE-GUN SIGHTS: (A) CLOSE-UP VIEW OF LEAF SIGHT; (B) ARRANGEMENT OF RIFLE SIGHTS

sists of a fixed foresight near the muzzle and a rearsight that is movable in a vertical plane, as shown in fig. 2. Vertical movement is calibrated in range (yards or meters) and is constrained to follow a curve that compensates for lateral drift of the bullet. A lateral adjustment is also provided to permit correction for the effect of wind.

Field Artillery, Mortars and Free Rockets.—Before discussing the sighting systems of these weapons, it is necessary to understand the arrangement of the basic parts of a gun mount. The top carriage is that portion of a gun mount that rotates (traverses) about a vertical axis and forms the support for the tipping parts of the gun. Any component of the sighting system attached to the top carriage will move with the gun in traverse, but will not move with it in elevation. The gun proper is usually mounted in

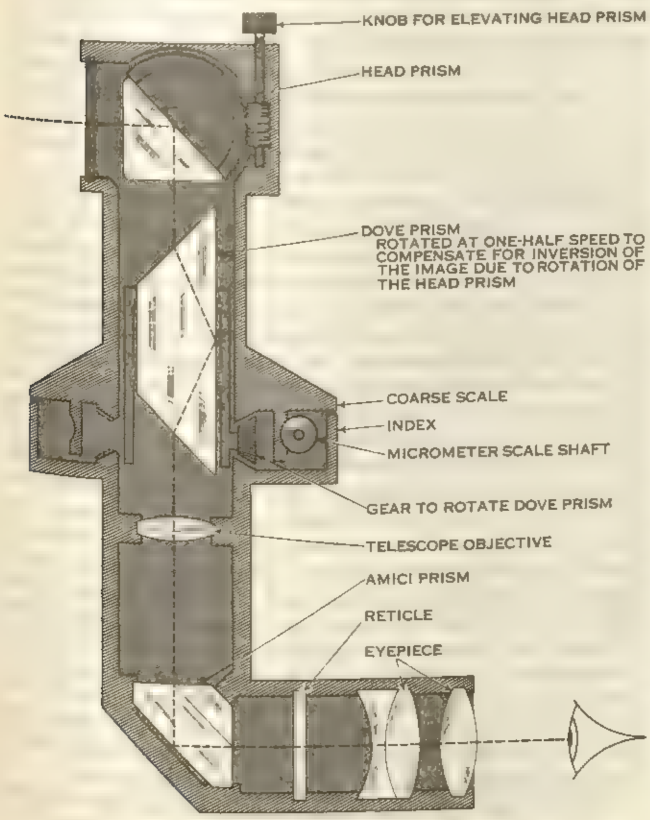

FIG. 3.—PANORAMIC TELESCOPE

a cradle attached to the top carriage by means of trunnions that form the horizontal axis about which the cradle and gun (tipping parts) rotate in elevation. The gun recoils in the cradle along the axis of the bore. Components of the sighting system attached to the cradle will move with the gun in both elevation and traverse, but will not move with the gun in recoil.

Since the elevating and traversing mechanisms are independent of each other, the laying of the gun can be simplified by having one member of the crew lay the gun in direction, and another lay it in elevation. It is, therefore, common practice to have the devices used for laying the gun in direction attached to the top carriage on one side (usually the left side) and the devices for laying in elevation attached to the cradle on the other side of the gun.

Mobile weapons are usually out of level (canted) due to irregularities in the ground and the axes of rotation are therefore not truly horizontal and vertical. When the gun is traversed under this condition, quadrant elevation will change and, conversely, when the gun is elevated the direction of fire will change. Sighting devices are so constructed that reference planes can be adjusted to the true vertical, hence laying accuracy is not impaired.

For protection from hostile fire, these weapons are usually emplaced in a position not visible to the enemy. Since the target can not be seen from the gun, laying in direction is accomplished

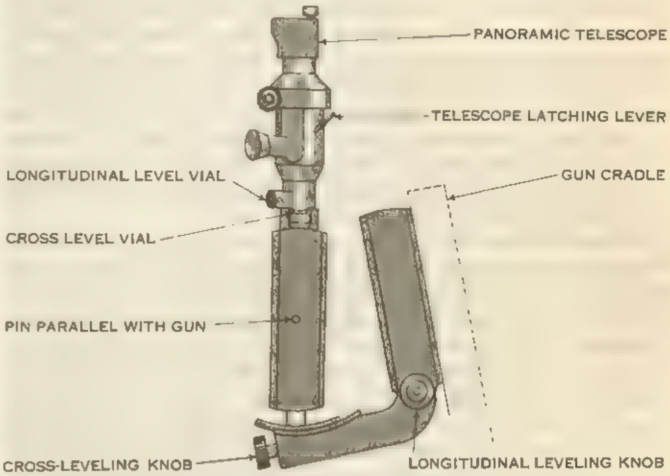

FIG. 4.—CANT COMPENSATING TELESCOPE MOUNT

by sighting on stakes set in the ground at a known direction from the gun. The horizontal angle between the gun axis and the gun-aiming stake line required to hit the target is measured from accurate maps and corrected by ballistic computations. A panoramic telescope which permits sighting in any direction from the same eyepiece position is used to measure this horizontal angle. (*See* fig. 3.) The panoramic telescope is mounted on the cradle and the mount compensates for the out-of-level condition by leveling the telescope about a bar parallel to the gun axis. (*See* fig. 4.) This determines the vertical plane containing the gun and permits the panoramic telescope to accurately measure the direction of fire.

Laying in elevation is accomplished by a device known as an elevation quadrant mounted on the cradle. The quadrant is also cross-leveled by rotation about a bar parallel to the gun axis so that elevation will be measured in the vertical plane. The precomputed quadrant elevation is set into the quadrant, offsetting a fore-and-aft spirit level. The gun is then elevated until the spirit level indicates that the gun has been elevated the desired amount. The elevation quadrant is sometimes incorporated into the compensating mount of the panoramic sight. Sights for mortars are usually so designed since laying of the mortar is performed by one man.

Antitank Guns and Recoilless Rifles.—As these weapons are employed at greater range than rifles or machine guns, they employ telescopic sights to increase the accuracy of fire. The telescopic sight contains a reticle with range markings (yards or metres) calibrated to the ammunition and offset at the longer

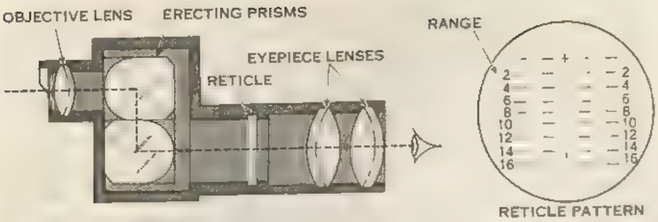

FIG. 5.—DIRECT FIRE TELESCOPIC SIGHT

ranges to compensate for drift. (*See* fig. 5.) The sight is mounted on the cradle (or directly on the recoilless rifle, which has no cradle) and in some cases provision is made for leveling the sight about an axis parallel to the gun to compensate for the error due to the gun being canted. In most cases the range of the target is estimated, but some guns are equipped with small-calibre spotting or ranging rifles to help determine the range. The spotting rifle is ballistically matched to the main gun. Both range and windage corrections are determined by trial fire with the small gun until a target hit is obtained before firing the main gun.

Tank Gunnery.—High-power telescopic sights are always used for tank gunnery because direct hits are required on small targets at long range. The physical configuration of the vehicle often makes it impractical to use a simple telescope. An articulated telescope, one with a rotating joint parallel with the gun trunnion, is sometimes used to bring the eyepiece to the gunner and eliminate movement as the gun is elevated. More frequently this problem is resolved by mounting a periscope in the turret roof and mechanically linking it to the gun to follow it in elevation. In some modern tanks, optical range finders (*see* RANGE FINDERS) are used to measure target range. Mechanical or electrical devices accurately compute the vertical and lateral corrections for each type of ammunition fired by the tank gun.

Naval Gunnery.—Modern naval guns are traversed and elevated by electronic and hydraulic servomechanisms. Direct laying by the gun crew is used only in emergencies. In normal practice, guns are sighted and the range of the target is determined either by radar or by optical means from director stations located high on the ship. The sighting data is electrically transmitted to a plotting room in the hull where mechanical or electronic computers generate the gun orders for electrical transmission to the turrets. A stable vertical gyroscope in the plotting room supplies data to the computer, usually called a range keeper, for conversion of director data into true horizontal and vertical tracking angles thus eliminating errors due to pitch and roll of the ship. The firing direction and quadrant elevation required to hit the target are computed by the range keeper with allowance for speed of both the firing ship and target. The laying angles are then converted, by data from the stable vertical gyroscope, into angles of turret elevation above deck plane and turret traverse in deck plane. The servomechanisms then keep the guns at the desired quadrant elevation and direction.

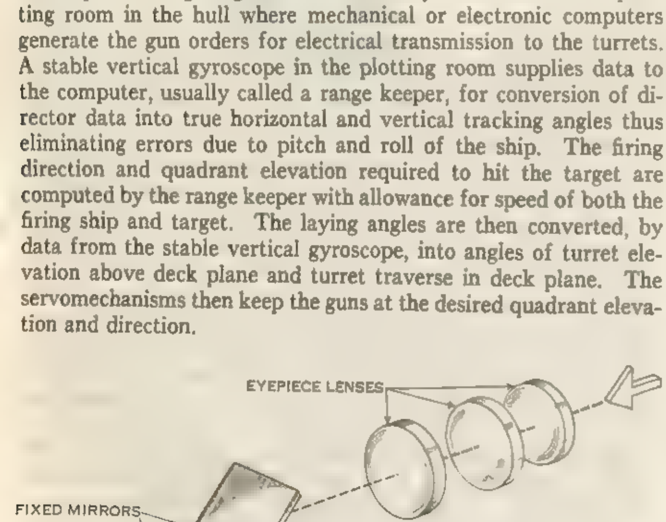

FIG. 6.—LEAD COMPUTING SIGHT

The guns are fired at any time, for ship motion does not disturb the lay of the guns.

See GUNNERY, NAVAL.

Antiaircraft Artillery.—Low-flying aircraft can be engaged successfully by antiaircraft artillery because the flight time of the shell is short. The high speed of jet aircraft makes it almost impossible to compute accurately the movement of the target during the time the projectile fired by an antiaircraft gun is in flight. The only effective weapons for use against high-flying aircraft are guided missiles or fighter planes.

Radar is used with antiaircraft artillery and missiles to measure the range to the target, but telescopic tracking in elevation and traverse usually gives greater accuracy than radar tracking, which is used only at long range or when visibility is poor. Electronic or mechanical computers are used to calculate the angle the gun must "lead" or be aimed ahead of the target. The gun is moved by electronic and hydraulic servomechanisms since the tracking rates are high.

Gyroscopes are used as the basic element in one type of lead-computing sight. Gyroscopic precession (*see* GYROSCOPE) is induced by the rotation of the sight while tracking the target in elevation and traverse. Precession is controlled by springs and weights designed to match the ballistics of the gun and adjusted as the target range changes. The amount the gyros precess against the restraining springs and weights is a measure of the required lead. This movement of the gyro is used to tilt mirrors in the sight (*see* fig. 6) which causes the target to appear ahead and above its true position; hence the gunner will track ahead by the appropriate amount.

Aircraft Gunnery.—Fighter aircraft carry rockets, machine guns or small-calibre cannon to engage both aerial and ground targets. Rigidly mounted guns are aimed by pointing the aircraft in the proper direction while approaching the target. Radar is used to measure the range to the target. A gyro lead-computing sight similar to that described above is used to compute the lead required to compensate for the motion of the firing aircraft and the target. (G. M. T.; W. T. AL.)

SIGIRI (SIGIRIYA), the Lion Rock, the ruin of a remarkable stronghold 45 mi. NNE of Kandy in the Central province of Ceylon. There a solitary pillar of granite rises to a height of 1,144 ft. from the plain, and the top actually overhangs the sides. On the summit of this pencil of rock there are five or six acres of ground; and on them, in A.D. 477, Kasyapa the Parricide, hoping to find an inaccessible refuge from his enemies, built his palace.

For a description of the Lion Rock and for the story of Kasyapa's crime *see* T. W. Rhys Davids, "Sigiri the Lion Rock" in *Journal of the Royal Asiatic Society*, vol. vii, pp. 191–220 (1875).

SIGISMUND (1368–1437), Holy Roman emperor from 1433, also king of Hungary by right of marriage from 1385 and by coronation from 1387, German king from 1411, king of Bohemia by inherited title from 1419 and by treaty from 1436, and Lombard king from 1431. A member of the House of Luxembourg, he was born on Feb. 15, 1368, a son of the emperor Charles IV (*q.v.*) by his last consort, Elizabeth of Pomorze. From his father he received Brandenburg (except the Neumark). Charles IV had also arranged the betrothal of Sigismund to Mary, daughter of King Louis I of Hungary and Poland; and after Charles IV's death (1378) Sigismund's half brother, the German king Wenceslas, who was also king of Bohemia, sent the boy to the Hungarian court. When Louis I died (1382), Sigismund's hopes sustained a setback: the Poles took Mary's sister Jadwiga instead of her as their queen; Mary's mother, Elizabeth of Bosnia, tried to prevent Sigismund's marriage; and a strong faction in Hungary offered the crown to Charles III (*q.v.*) of Naples. Sigismund however consummated his marriage to Mary in 1385, Charles of Naples was murdered in 1386, and finally Sigismund was crowned on March 31, 1387. Even so, his rule was still challenged by partisans of the Neapolitan king Ladislas, Charles III's son; to raise funds, he pawned Brandenburg to his cousin Jobst of Moravia in 1388; and Mary's death (1395) weakened his position.

Sigismund meanwhile kept his eye on the Bohemian succession: sometimes in collaboration and sometimes in rivalry with Jobst,

he intervened in the movements against Wenceslas. In 1396 he came to terms with Wenceslas. Then he turned his attention to the Turks, who had taken advantage of the troubles in Hungary to overrun Serbia and Bulgaria. Pope Boniface IX called for a crusade against them, and Sigismund advanced down the Danube Valley with a great army of the chivalry of Europe. He captured Vidin and laid siege to Nicopolis (Nikopol); but in September 1396 Sultan Bayazid I inflicted a crushing defeat on the crusaders. Escaping via Constantinople, Sigismund returned to Hungary in 1397.

In August 1400 Wenceslas was deposed from the German kingship, which was transferred to Rupert of the Palatinate. Sigismund sought to exploit this situation to get Bohemia from Wenceslas. In April 1401 he was arrested by conspirators in Buda: held prisoner at Siklos, he was released in the autumn. Returning to Bohemia, he had Wenceslas arrested in March 1402 but was soon called away to confront an invasion of Hungarian Dalmatia by Ladislas of Naples. During this Dalmatian War, Wenceslas was released and restored to his Bohemian throne. Ladislas, forced to abandon his attempt on the Hungarian crown, sold his Dalmatian conquests to the Venetians, against whom Sigismund became involved in intermittent war for years. In 1408 Sigismund married Barbara of Cilli, who bore him a daughter, Elizabeth, in 1409.

When King Rupert died, three of the German electors chose Sigismund as king on Sept. 20, 1410, but others chose Jobst in October. Jobst died in January; and on July 21, 1411, at Frankfurt, a new election assured the crown to Sigismund.

Having gone to Italy to reduce the Venetians, with whom he made a five-year armistice in April 1413, Sigismund had an interview with Pope John XXIII (*q.v.*), whom Ladislas of Naples had expelled from Rome. It was Sigismund who induced John to announce the summoning of the Council of Constance (*q.v.*) for 1414. Then at last Sigismund entered his German kingdom. Having been crowned at Aachen on Nov. 8, 1414, he arrived at Constance, where he made himself a leading spirit in the council. The degree of his responsibility for the arrest and burning of John Huss (*q.v.*) is a matter of controversy. Sigismund was concerned, however, not only to heal the great schism of the papacy but also to establish peace in Christendom so that a new crusade could be launched against the Turks. After going to Languedoc to persuade Ferdinand I of Aragon to disavow the antipope Benedict XIII (1415), he went to Paris, then to London in the hope of reconciling Charles VI of France and Henry V of England. Eventually, however, he allied himself with Henry; and this change of policy compromised his role of mediator at Constance.

The death of Wenceslas (1419) made Sigismund heir to Bohemia, but the Hussite Wars there cost him years of effort, with one military humiliation after another, before he could get his title recognized (*see* HUSSITES). His preoccupation with central Europe led him to neglect German affairs, but three of his acts were of great consequence: (1) his granting of Brandenburg by successive stages, from 1411, to Frederick VI of Hohenzollern (*see* HOHENZOLLERN); (2) the marriage of his daughter, in 1422, to Albert V of Austria, the future German king Albert II (*see* HABSBURG); and (3) his grant of the Saxon electorate, in 1423, to Frederick IV of Meissen (*see* WETTIN). After the Imperial Diet at Nürnberg in 1422, when he appealed in vain for effective help against the Hussites, he did not return to Germany till 1430. The Union of Bingen (1424), between the German electors, was a step toward strengthening the princes against his royal authority.

A campaign against the Turks resulted in a defeat for Sigismund in 1428, but peace was made next year. In 1431 he went to Italy again, to receive the Lombard crown in Milan on Nov. 25. The wars of the Italian states and the conflict between Pope Eugenius IV and the Council of Basel (*q.v.*) delayed Sigismund's coronation as Holy Roman emperor till May 31, 1433.

The *Compactata* of Prague (*see* HUSSITES) paved the way for peace in Bohemia. In July 1436 Sigismund approved them, and in August he was finally received as king in Prague. He died at Znojmo, in Moravia, on Dec. 9, 1437.

BIBLIOGRAPHY.—There is a German translation of the life of Sigismund by his contemporary Eberhard Windecke, *Das Leben König Sigmunds* (1886). The fullest biography is J. Aschbach, *Geschichte Kaiser Sigmunds*, 4 vol. (1838–45). *See* also *Die Urkunden Kaiser Sigmunds*, ed. by W. Altmann (1896–1900); H. Horváth, *Zsigmond király es kora*, with summary in German (1937).

SIGISMUND I THE OLD (Polish ZYGMUNT STARY) (1467–1548), king of Poland from 1506, was born on Jan. 1, 1467, the fifth son of Casimir IV Jagiello and Elizabeth of Austria. He learned the art of government as prince of Glogów, which he transformed into a model state, and subsequently as governor of Silesia and margrave of Lusatia under his brother Vladislav of Bohemia.

Sigismund was elected grand prince of Lithuania on Sept. 13, 1506, and king of Poland on Dec. 8, 1506, in succession to his brother Alexander. In Poland his first step was to recover control of the mint and to put it in the hands of capable merchants and bankers (Jan Boner, the Betman family, and others), who reformed the currency and developed commerce. Apart from them, he relied on the support of the magnates for internal affairs and came into conflict with the middle *szlachta*, or gentry, which at that time was beginning to assert itself. Popular movements against the patrician governments of the Prussian cities were suppressed with severity. On the other hand, though he was a devout Catholic himself, Sigismund would not tolerate the persecution of non-Catholics; he upheld the rights of his Orthodox subjects against the Catholic minority of magnates which dominated the Lithuanian senate; and he protected the Jews.

In foreign policy Sigismund's principal advisers were Jan and Jaroslaw Laski and Jan Tarnowski. For the first 20 years of his reign Poland was almost continuously at war with Muscovy; and in order to break the coalition between Muscovy and the Habsburgs he had to resign to the latter his claims to the Hungarian crown (Treaty of Vienna, July 22, 1515). His southeastern borderland, meanwhile, was so frequently ravaged by the Tatars that a small permanent army had eventually to be established there. Quarrels with the grand masters of the Teutonic Order (*q.v.*), who wanted to release Prussia from Polish suzerainty, were ended in 1525, when the grand master Albert (*q.v.*), having professed Lutheranism, did public homage as duke of Prussia to Sigismund at Cracow.

On Feb. 8, 1512, Sigismund had married Barbara, daughter of the Hungarian prince Stephen Zápolya, but she died three years later, leaving only daughters. The king's second marriage (April 18, 1518) was to the beautiful Bona Sforza (1494–1557), daughter of Gian Galeazzo Sforza, duke of Milan. By her he had a son, who was to succeed him as Sigismund II (*q.v.*), and four daughters: Isabella (1519–59), married in 1539 to the Hungarian king John Zápolya; Sophia (1522–75), married in 1556 to Henry II of Brunswick-Wolfenbüttel; Anna (1523–96), married in 1576 to Stephen (*q.v.*) Báthory; and Catherine (1526–83), married in 1562 to John III of Sweden, from whom the Vasa kings of Poland descended. Bona Sforza, however, used her financial talents mainly for her own benefit and became generally detested for corruption.

A lover of the fine arts and, especially, of architecture and sculpture, Sigismund brought Italian artists to Cracow and promoted the development of the Polish variety of Italian Renaissance style. From his 60th year onward, however, his energy and capacity declined, though his herculean physique retained the appearance of vigour. Sigismund died in Cracow on April 1, 1548.

See Z. Wojciechowski, *Zygmunt Stary* (1946); W. Pociecha, *Królowa Bona*, 4 vol. (1949–58). (ST. HE.)

SIGISMUND II AUGUSTUS (Polish ZYGMUNT AUGUST) (1520–1572), king of Poland as sole ruler from 1548, was born in Cracow on Aug. 1, 1520, the son of Sigismund I and Bona Sforza. He was crowned in 1530, during his father's lifetime, and ruled Lithuania from 1544. In 1543 he married Elizabeth of Austria, daughter of the German king and future Holy Roman emperor Ferdinand I; she died childless in 1545 and Sigismund in 1547 married the beautiful Barbara Radziwill, who belonged to a family of Lithuanian magnates (*see* RADZIWILL).

On his father's death (April 1, 1548), Sigismund's actual reign in Poland began. At his first *Sejm* (Diet), in October 1548, he came into conflict with the rising power of the *szlachta*, or gentry. With secret support from Austria and from the queen mother, the *szlachta* threatened to renounce its allegiance to Sigismund unless he repudiated his wife and shook off the influence of the Radziwills. His firm refusal produced a reaction, and at the second *Sejm* (1550) the *szlachta* was less turbulent. Barbara was crowned queen of Poland on Dec. 7, 1550, but died childless in 1551. In 1553 Sigismund married Catherine, his first wife's sister; this union also was childless.

Sigismund's reign was a period of internal turmoil and external expansion (*see* POLAND: *History*). The doctrines of the Reformation, which had been received in Poland clandestinely during Sigismund I's reign, spread very widely throughout the *szlachta*, and the democratic upheaval placed all political power in the latter's hands. The *szlachta* forced the magnates to restore the crown lands which had come into their possession, and demanded a centralized administration of the state.

The collapse of the Livonian branch of the Teutonic Order led to Poland's acquisition of Livonia in 1559, but Sigismund's most striking and personal achievement was the real union of Poland and Lithuania, brought about during the *Sejm* at Lublin in 1569, despite opposition by the separatist Lithuanian magnates. The last male of the Jagiellos in the direct line, Sigismund died at Knyszyn on July 7, 1572.

See O. Halecki, *Dzieje unii jagiellońskiej*, vol. ii (1920). (ST. HE.)

SIGISMUND III (1566–1632), king of Poland from 1587 and king of Sweden from 1592 to 1599, was born at Gripsholm on June 20, 1566, the elder son of John III of Sweden and his consort Catherine, sister of Sigismund II of Poland. He belonged to the Vasa dynasty through his father, and to the Jagiello dynasty through his mother, who educated him as a Catholic. After the death of Stephen (*q.v.*) Báthory, he was elected king of Poland on Aug. 19, 1587, thanks to his aunt, Anne (Stephen's widow), and to the Polish chancellor, Jan Zamoyski (*q.v.*). He was crowned at Cracow on Dec. 28, 1581.

From the first Sigismund was antipathetic to the majority of his subjects. The *szlachta*, or gentry, who could not understand his refinement, regarded his calm and reserved manner as haughtiness. His political views, moreover, were diametrically opposed to the omnipotent Zamoyski's. In foreign policy, Sigismund aimed at alliance between Poland and the Austrian Habsburgs with the double object of forming a solid Catholic front against the Turks and of exerting greater influence on Sweden. No benefit, however, could be expected from any alliance unless the Polish constitution were reformed so as to increase the royal power.

On May 31, 1592, Sigismund married Anne, daughter of the archduke Charles of Inner Austria; and at the *Sejm* or Diet in the autumn Zamoyski accused him of wanting to cede his throne to the Habsburgs. Finally, however, king and chancellor patched up their quarrel; and after the death of Sigismund's father (Nov. 17, 1592) Zamoyski obtained the Diet's permission for Sigismund to go to Sweden to secure the succession there (summer 1593).

Having consented to the maintenance of Lutheranism in Sweden, Sigismund was crowned at Uppsala on Feb. 19, 1594. On July 19 he departed for Poland, leaving his uncle, Charles (*see* CHARLES IX), as regent. The regent, however, soon began to subvert Sigismund's authority. In 1598 Sigismund landed in Sweden with an army, but was defeated at Stångebro (Sept. 25) and had to accept humiliating terms before leaving the country. The next year Charles had him formally deposed by the Swedish Diet. Sigismund refused to renounce his rights and embarked on hostilities against the Swedes (1600).

In Poland, meanwhile, Sigismund had favoured the ecclesiastical Union of Brześć (1596), which brought numbers of his Orthodox subjects into the Roman Catholic communion. The oppressed Cossacks of the Ukraine rebelled in the name of Orthodoxy, and the Polish Protestants made common cause with them. To reinforce the pro-Austrian faction at his court, Sigismund, a widower from 1598, soon made plans to marry his first wife's sister Constantia, thereby antagonizing Zamoyski again. At the *Sejm* of 1605 the king tried to introduce decision by a majority of votes instead of unanimity, but Zamoyski frustrated this reform. Zamoyski died in June, and on Dec. 11, 1605, Sigismund and Constantia were married.

Zamoyski's death removed all restraint from his extremist partisans, and from 1606 to 1608 Poland was in a state of civil war and anarchy. There followed a long war against Muscovy (1609–19; *see* RUSSIAN HISTORY); and in 1617 the Polish-Swedish War, which had been interrupted by a truce in 1611, broke out again. Since Sigismund at the same time brought Poland into conflict with Turkey (1617–21), the Swedish king Gustavus II Adolphus was able to occupy Livonia, capturing Riga in 1621. After another truce (1622–25), Gustavus in 1626 attacked Polish Pomorze also. Finally the six-year Truce of Altmark was signed in 1629.

Sigismund died in Warsaw on April 30, 1632. His son by Anne succeeded him as Wladyslaw IV. By Constantia he left the future king John Casimir and four other children. (ST. HE.)

SIGNAC, PAUL (1863–1935), French painter, developer, with Georges Seurat, of the technique called Neoimpressionism, was born in Paris, Nov. 11, 1863. After youthful attempts to study architecture, he turned, at the age of 18, to painting. Through Armand Guillaumin, Signac became a convert to the tone division of Impressionism, and he was represented by several landscapes at the exhibition of the Maison Dorée in 1886.

In 1884 Signac had helped found the Salon des Indépendants. There he met Seurat, whom he initiated into the broken-colour technique of Impressionism. The two went on to the method they called Pointillism or Neoimpressionism. They continued to divide their canvases into minute dabs of pure pigment, as had the Impressionists, but they adopted an exact, geometrical system of applying the dots instead of the somewhat intuitive application of the earlier masters. This technique was not unlike the mechanical process of printing photographic illustrations in colour by means of halftones. Some critics denounced Signac's landscapes as monotonous and mathematical rather than artistic, but others found that the optical mixture of detached colours separated by pure white created an admirable luminosity. In water colours Signac used the principle in a much freer manner. After 1886 Signac took part regularly in the annual Salon des Indépendants, to which he sent landscapes, seascapes, and decorative panels. He traveled widely over Europe with Seurat and other painters, and in his later years painted many scenes of Paris, Viviers, and other French cities.

Signac produced much critical writing and was the author of *De Delacroix au néo-impressionnisme* (1899) and *Jongkind* (1927). The former book is an exposition of Pointillism or Neoimpressionism as developed by Seurat and himself. Signac died in Paris on Aug. 15, 1935. Paintings by Signac may be seen at the Museum of Modern Art and in the Frick collection in New York city; at the Musée National d'Art Moderne in Paris; and in many other public collections.

SIGNAL, a word common in slightly different forms to nearly all European languages, derived from Lat. *signum*, "a mark" or "sign," a means of transmitting information, according to some prearranged system or code, in cases where a direct verbal or written statement is unnecessary, undesirable, or impracticable. For military signaling *see* SIGNAL COMMUNICATION, MILITARY; *see* also RAILWAY: *Communications and Signaling: Signals*.

SIGNAL COMMUNICATION, MILITARY. Signal communication, or signaling, has long played an important role in warfare. It serves to provide the means for transmitting information from reconnaissance and other units in contact with the enemy, and the means for exercising command by transmitting the orders and instructions of commanders to their subordinates. It comprises all means of transmitting messages, orders, and reports, both in the field and between army headquarters and field installations. In U.S. Army usage, signal communication includes automatic transmission of data over military wire and radio circuits; between the electronic computers and control systems employed in gun laying, air navigation, and guided-missile control; and in the various logistic and clerical activities of the military arms and services. Signal communication in some armies also

includes photography and television.

The history of the science of communication can be divided into four phases: (1) the early period of origin and growth up to the invention of the electric telegraph and the Morse code of dots and dashes in the mid-19th century; (2) the advent of the telegraph, the telephone, and wireless radio and their development up to the outbreak of World War I in 1914; (3) development during World War I and up to the beginning of World War II; and finally (4) the great expansion during and after World War II.

Early Development.—Messengers have been employed in war since ancient times and still constitute a valuable means of communication. Alexander, Hannibal, and Caesar each developed an elaborate system of relays by which messages were carried from one messenger post to another by mounted messengers traveling at top speed. They were thus able to maintain contact with their homelands during their far-flung campaigns and to transmit messages with surprising speed. Genghis Khan at the close of the 12th century not only emulated his military predecessors by establishing an extensive system of messenger posts from Europe to his Mongol capital but also utilized homing pigeons as messengers. As he advanced upon his conquests he established pigeon relay posts across Asia and most of Europe. He was thus able to utilize these messengers to transmit instructions to his capital for the governing of his distant dominions. Before the end of the 18th century European armies used the visual telegraph system devised by Claude Chappe, employing semaphore towers or poles with movable arms. The Prussian Army in 1833 assigned such visual telegraph duties to engineer troops.

At the same time that these elementary methods of signal communication were being evolved on land, a comparable development was going on at sea. Early signaling between naval vessels was by prearranged messages transmitted by flags, lights, or the movement of a sail. Codes were developed in the 16th century that were based upon the number and position of signal flags or lights or on the number of cannon shots. In the 17th century, Adm. Sir William Penn (1621–70) and others developed regular codes for naval communication, and toward the close of the 18th century, Adm. Richard Kempenfelt developed a plan of flag signaling similar to that now in use. Later Sir Home Popham increased the effectiveness of ship-to-ship communication by improved methods of flag signaling.

Advent of Electrical Signaling.—Despite the early pioneering efforts on land and sea the real development of signal communication in war did not come until after invention of the electric telegraph by Samuel F. B. Morse. In his successful demonstration of electric communication between Washington, D.C., and Baltimore, Md., in 1844, he provided a completely new means of rapid signal communication. The development of the Morse code of dots and dashes used with key and sounder was soon used to augment the various means of visual signaling. Vice-Adm. Philip Colomb's flash signaling, adopted in the British Navy in 1867, was an adaptation of the Morse code to lights. The first application of the telegraph in time of war was made by the British in the Crimea in 1854, but its capabilities were not well understood and it was not widely used. Three years later, in the Indian Mutiny, the newly established telegraph, which was controlled by the British, was a deciding factor.

In the U.S. Civil War (1861–65) wide use was made of the electric telegraph. In addition to its employment in spanning long distances under the civilian-manned military telegraph organization, mobile field service was provided in the Union Army by wagon trains equipped with insulated wire and lightweight poles for the rapid laying of telegraph lines. Immediately before and during the Civil War visual signaling also received added impetus through the efforts of two British officers, Capt. Frank Bolton of the Army and Capt. Colomb of the Royal Navy, and Maj. Albert Myer, signal officer of the U.S. Army (*see* SIGNAL CORPS). The two British officers, working together, and Myer, working independently, arrived at the same end. They developed a system, applying the Morse code of dots and dashes, for spelling out messages by flags by day and lights or torches by night. Another development for light signaling placed a movable shutter, controlled by a key, in front of a strong light. An operator, opening and closing the shutter, could produce short and long flashes in accordance with the Morse code and this could spell out messages.

Simultaneously with U.S. and British developments in military telegraph, the Prussian and French armies also organized mobile telegraph trains. During the short, decisive Prussian campaign against Austria in 1866, field telegraph enabled Count Helmuth von Moltke, the Prussian commander, to exercise command over his distant armies. Soon afterward the British organized their first field telegraph trains in the Royal Engineers. In the British Abyssinian campaign, 1867–68, Sir Robert Napier's forces made extensive use of Bolton and Colomb's new method of visual signaling and of the field telegraph. Success was immediate and remarkable.

Another instrument was added to the techniques for visual signaling through the development of the heliograph. It employed two adjustable mirrors so arranged that a beam of light from the sun could be reflected in any direction. The beam was interrupted by a key-operated shutter that permitted the formation of the dots and dashes of the Morse code. Where climatic conditions were favourable this instrument found much use, notably by the British Army in India and the United States Army in the southwestern U.S. Because consistency and regularity of sunshine were important, the heliograph was never widely adopted throughout the armies of continental Europe.

The invention of the telephone in 1876 was not followed immediately by its adoption and adaptation for military use. This was probably due to the fact that the compelling stimulation of war was not present and to the fact that the development of long-distance telephone communication was not achieved for many years. The telephone was used by the United States Army in the Spanish-American War, by the British in the South African War and by the Japanese in the Russo-Japanese War. This military use was not extensive and it made little material contribution to the development of voice telephony. Between the start of the 20th century and the outbreak of World War I, military adaptation of the telephone did take place, but its period of major growth had not yet arrived.

Near the close of the 19th century, a new means of military signal communication made its appearance—the wireless telegraph, or, as named in the United States and Canada—the radio. In 1894 Sir Oliver Lodge successfully demonstrated that the electromagnetic waves first discovered by Heinrich Hertz, and later studied by James C. Maxwell, could be guided and used for signaling. He was followed by Marconi, who developed but did not discover the use of these waves for signaling. The major powers throughout the world were quick to see the wonderful possibilities of this new agency for military and naval signaling. Its development was rapid and continuous and, by 1914, it was adopted and in extensive use by all the armies and navies of the world. It soon became apparent that wireless telegraphy was not an unmixed blessing to armies and navies, because it lacked secrecy and messages could be heard by the enemy as well as by friendly forces. This led to the development of extensive and complicated codes and ciphers as necessary adjuncts to military signaling. The struggle between the cryptographer and the cryptanalyst expanded greatly with the adoption of radio and continued to be a major factor affecting its military use. (*See* CRYPTOLOGY.)

From World War I to 1940.—The onset of World War I found the opposing armies equipped to a varying degree with modern means of signal communication but with little appreciation of the enormous load that signal systems must carry to maintain control of the huge forces that were set in motion. The organization and efficiency of the armies varied greatly. At one end of the scale was Great Britain, with a small but highly developed signal service, and at the other end stood Russia, with a signal service inferior to that of the American Union Army at the close of the Civil War. The fact that commanders could not control, coordinate, and direct huge modern armies without efficient signal communication quickly became apparent to both the Allies and the Central Powers. The Germans, despite years of

concentration on the Schlieffen plan, failed to provide adequately for communication between higher headquarters and the rapidly marching armies of the right wing driving through Belgium and northern France. This resulted in a lack of coordination between these armies which caused a miscarriage of the plan, a forced halt in the German advance, and the subsequent withdrawal north of the Marne. On the Allied side, the debacle of the Russian forces in East Prussia—a crushing defeat at the hands of Gen. Paul von Hindenburg in the Battle of Tannenberg—was largely due to an almost total lack of signal communication.

As the war progressed there was a growing appreciation of the need for improved electrical communications of much greater capacity for the larger units and of the need within regiments for electrical communications, which had heretofore been regarded as unessential and impractical. Field telephones and switchboards were soon developed and those already in existence were improved. An intricate system of telephone lines involving thousands of miles of wire soon appeared on each side. Pole lines with many crossarms and circuits came into being in the rear of the opposing armies and buried cables and wires laid in trenches were installed in the elaborate trench systems leading to the forwardmost outposts. The main arteries running from the rear to the forward trenches were crossed by lateral cable routes roughly parallel to the front. Thus there grew an immense gridwork of deep buried cables, particularly on the German side and in the British sectors of the Allied side with underground junction boxes and test points every few hundred yards. The French used deep buried cable to some extent but generally preferred to string their telephone lines on wooden supports set against the walls of deep open trenches. Thus electrical communication in the form of the telephone and direct-current telegraph gradually extended to the smaller units until front-line platoons were frequently kept in touch with their company headquarters through these mediums.

At the beginning of the war most of the armies were using military telegraph instruments employing an alternating current at frequencies from 500 to 700 cycles per second. These instruments could transmit well through the long and generally defective wire lines used in open warfare. However, when used in the trench systems in close proximity to the enemy it was found that their signals could be readily intercepted by using amplifiers associated with earth induction pickup devices. A new type of telegraph instrument was soon developed which transmitted an interrupted direct current that could not be picked up by the listening devices then in use.

Despite efforts to protect the wire lines, they were frequently cut at critical times as the result of the intense artillery fires. This led all the belligerents to develop and use radio (wireless) as an alternate means of communication. Prewar radio sets were too heavy and bulky to be taken into the trenches and they also required large and highly visible aerials. Radio engineers of the belligerent nations soon developed smaller and more portable sets powered by storage batteries and using low, inconspicuous aerials. Although radio equipment came to be issued to the headquarters of all units, including battalions, the ease of enemy interception, the requirements for cryptographing or encoding messages, and the inherent unreliability of these early systems caused them to be regarded as strictly auxiliary to the wire system and reserved for emergency use when the wire lines were cut. Visual signaling returned to the battlefield in World War I with the use of electric signal lamps. Pyrotechnics, rockets, Very pistols, and flares had a wide use for transmitting prearranged signals. Messenger service came to be highly developed and motorcycle, bicycle, and automotive messenger service was employed. Homing pigeons were extensively used as one-way messengers from front to rear and acquitted themselves extremely well. Dogs also were used as messengers and, in the German Army, reached a high degree of efficiency.

A new element in warfare, the airplane, introduced in World War I, immediately posed a problem in communication. During most of the war, communication between ground and air was difficult and elementary. To make his reports the pilot had to land or drop messages, and he received instructions while in the air from strips of white and black cloth called "panels" laid out in an open field according to prearranged designs. Extensive efforts were made to use radiotelegraph and radiotelephone between the airplanes and ground headquarters. The closing stages of the war saw many planes equipped with radio but the service was never satisfactory or reliable and had little influence on military operations.

During World War I, wireless telegraph communication was extensively employed by the navies of the world and had a major influence on the character of naval warfare. High-powered shore and ship stations made possible wireless communication over long distances.

World War I left a host of lessons to be studied by the army, naval, and air force personnel of all nations. Important among these lessons was the need to improve mobility, firepower, communication, and the effectiveness of air power. Advances in military communications after the war were greatly aided by the large increase in electronic and communication development for civilian purposes.

The growth of radiobroadcasting following World War I brought into existence in most nations a greatly increased interest in communication engineering and the expansion of manufacturing facilities to exploit the new art. Carrier telephony on wire systems also made great advances in providing for several unconflicting conversations over the same wires. There was a rapid growth in long-distance telephone techniques and plant. The design of amplifiers for telephone repeaters made rapid progress.

One of the war lessons learned in most of the major nations was the compelling need for scientific research and development of equipment and techniques for military purposes. Although the amount of funds devoted to military development during the period from World War I to World War II was relatively small, the modest expenditures served to establish a bond between industry, science, and the armed forces of the major nations.

Of great importance in radio communication was the pioneering by the amateurs and by industry and science in the use of very high frequencies. These developments opened up to the armed services the possibilities of portable short-range equipment for mobile and portable tactical use by armies, navies, and air forces. Military work in these fields was carried out actively in Germany, Great Britain, and the United States. As early as 1938 Germany had completed the design and manufacture of a complete line of portable and mobile radio equipment for its Army and Air Force.

The increased interest in scientific research and development on the part of the armed services brought about the birth of radar (*q.v.*), which was destined to become one of the major technological advances of World War II. Signifying radio detecting and ranging, radar was developed for long-range location and tracking of enemy aircraft and for the direction of antiaircraft fire. It used sharply beamed short pulses of radio energy that were reflected back from the surfaces of aircraft in flight to give a visual signal indication on the face of a receiver oscilloscope. Using radar, it became possible to detect and locate enemy aircraft at distances of 100 to 150 mi., which enabled the defending air force then to take off and intercept enemy bombers. In Britain, radar became one of the major factors that enabled the British to meet and neutralize mass German bombing attacks during the Battle of Britain. Although, strictly speaking, radar is not used for communication, it formed part of the complex communication systems required for antiaircraft warning and fire-control nets. The employment of radar in IFF systems (identification, friend or foe) to distinguish friendly aircraft from hostile on the oscilloscopes of search sets did in fact serve a communication function.

Between World Wars I and II the printing telegraph, commonly known as the teleprinter or teletypewriter machine, came into civilian use and was incorporated in military wire-communication systems but military networks were not extensive. Before World War II military radioteleprinter circuits were nonexistent.

Another major communication advance that had its origin and early growth during the period between World Wars I and II was frequency-modulated (FM) radio. Developed during the late 1920s and early 1930s by Edwin H. Armstrong, inventor and a major in the United States Army Signal Corps during World War I,

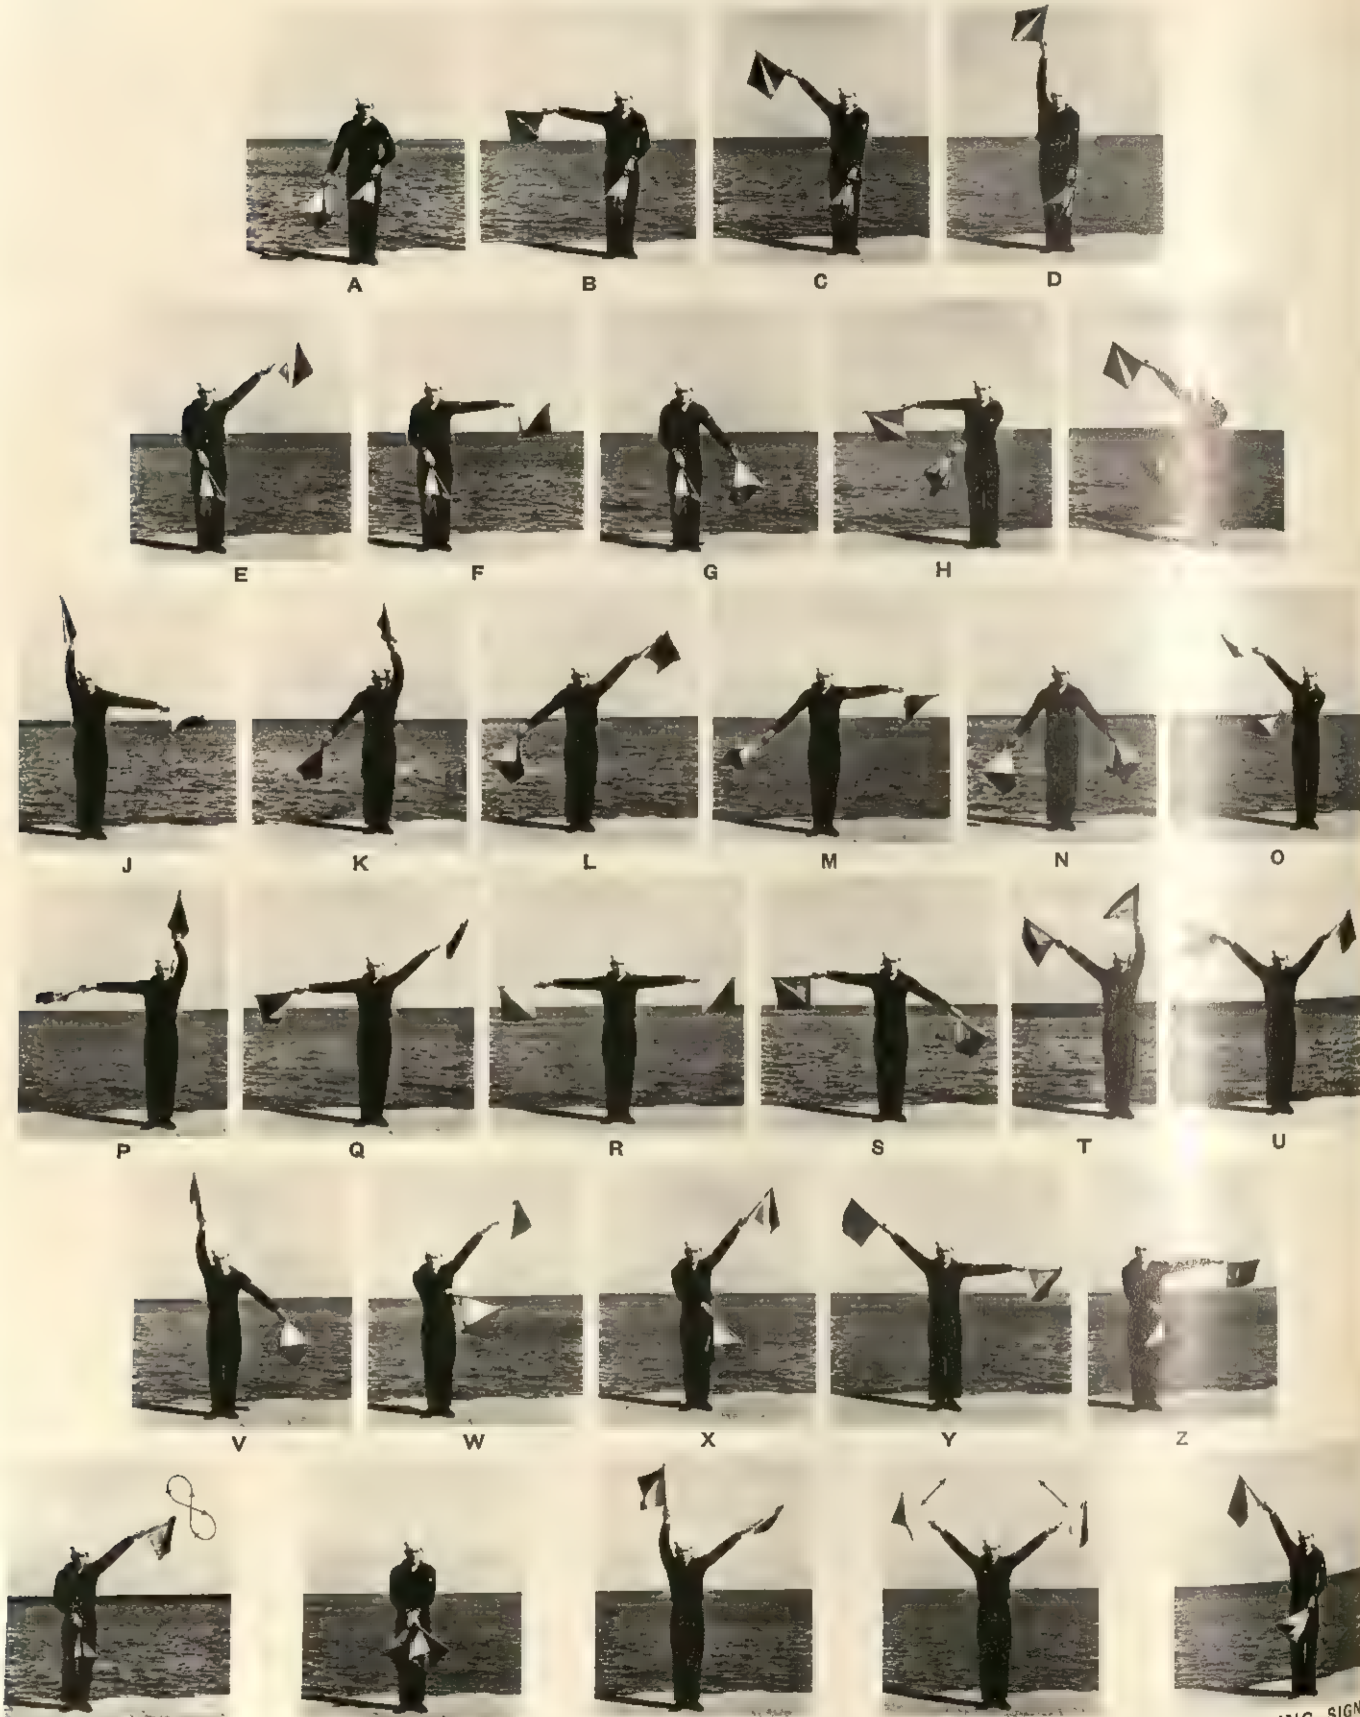
INTERNATIONAL CODE FLAGS AND PENNANTS

The two-letter signal R Y flying from the masthead signifies "Crew have mutinied." The other two-letter groups on the halyards hoisted to the yardarm have the following meanings: N C—"I am in distress and require immediate assistance"; K A—"My vessel is very seriously damaged"; K T—"Have you a line-throwing apparatus?"; I X—"I have received serious damage in collision"; C G—"You should alight as near to me as possible"; A D—"I must abandon my vessel."

SIGNAL COMMUNICATION, MILITARY



SEMAPHORE FLAG SIGNALS

Numerals from 1–9 are the same as the first nine letters of the alphabet, sent after the "numeral" signal; zero is the same as the letter J

this new method of modulation offered heretofore unattainable reduction of the effect of ignition and other noises encountered in vehicular radio applications. It was first adapted for military use by the United States Army, which, prior to World War II, had under development tank, vehicular, and man-pack frequency-modulated radio transmitters and receivers.

On the eve of World War II, all nations employed generally similar methods for military signaling. The messenger systems included foot, mounted, motorcycle, automobile, airplane, homing pigeon, and the messenger dog. Visual agencies included flags, lights, panels for signaling airplanes, and pyrotechnics. The electrical agencies embraced wire systems providing telephone and telegraph service, including the printing telegraph. Both radiotelephony and radiotelegraphy were in wide use, but radiotelephony had not as yet proved reliable and satisfactory for tactical military communication. The navies of the world entered World War II with highly developed radio-communication systems, both telegraph and telephone, and with development under way of radar and sonar (sound navigation and ranging) and many other electronic navigational aids. Blinker-light signaling was still employed. The use of telephone systems and loud-speaking voice amplifiers on naval vessels had also come into common use. Air forces employed wire and radio communication to link up their bases and landing fields and had developed airborne long-range, medium-range, and short-range radio equipment for air-to-ground and air-to-air communication.

World War II and After.—In the communication and electronics field, World War II was in one sense similar to World War I—the most extravagant prewar estimates of military, naval, and air communication requirements soon proved to represent only a fraction of the actual demand. Requirements for all kinds of communication equipment and for improved quality and quantity of communications pyramided beyond the immediate capabilities of industry. Expansion of manufacturing facilities became vital, and the expansion of research and development activities in the communications-electronics field was unprecedented. The early German blitzkrieg, with tank and armoured formations, placed a new order of importance on reliable radio communication. The development of the air, infantry, artillery, and armoured team created new requirements for split-second communication by radio between all members. Portable radio sets were provided as far down in the military echelons as the platoon. In every tank there was installed at least one radio and in some command tanks as many as three. In the field of wire communications multiconductor cables were provided; they could be rapidly reeled out and on them as many as four conversations could take place simultaneously through the use of carrier telephony. The Germans were the first to bring forth this type of military long-range cable and their example was promptly followed by both the British and the U.S. forces. High-powered mobile radio sets became common at division and regimental level. With these sets telegraph communication could be conducted at distances of more than 100 mi. with vehicles in normal motion on the road. Major telephone switchboards of much greater capacity were needed. These were developed, manufactured, and issued for use at all tactical headquarters to satisfy the need for the greatly increased number of telephone channels required to coordinate the movements of field units whose mobility had been expanded many times.

Radio relay, born of the necessity for mobility, became the outstanding communication development of World War II. Sets employing frequency modulation and carrier techniques were developed and used, as were also radio relay sets that used radar pulse transmission and reception techniques and multiplex time-division methods for obtaining many voice-channels from one radio carrier. Radio relay telephone and teletypewriter circuits spanned the English Channel for the Normandy landing and later furnished important communication service for Gen. George S. Patton, after his breakout from the Normandy beachhead.

The need for communication between the homelands and many far-flung theatres of war gave rise to the need for improved long-range overseas communication systems. A system of radioteletypewriter relaying was devised, by which a radioteletypewriter operator in Washington, London, or other capitals could transmit directly by teleprinter to the commander in any theatre of war. In addition, a system of torn-tape relay centres was established so that tributaries could forward messages through the major centres and retransmission could be effected in a minimum of time by transferring the perforated tape message from the receiving to the transmitting positions. In addition a system of holding teletypewriter conferences was developed. These conferences were called "telecon" and enabled a commander or his staff at each end to view on a screen the incoming teletypewriter messages as fast as the characters were received. Questions and answers could thus be passed rapidly back and forth over the thousands of miles separating the Pentagon in Washington, D.C., for example, from SHAEF headquarters in Europe or Gen. Douglas MacArthur's headquarters in the Far East.

During the latter years of the war, new and improved communication and electronic devices came forth from research and development in ever-increasing numbers. A new long-range electronic navigation device, known as loran, used for both naval vessels and aircraft, appeared, as did short-range navigational systems, called shoran. Combinations of radar and communications for the landing of aircraft in zero visibility were perfected. One such system was the GCA or ground-controlled approach system. Combinations of radio direction-finding, radar, and communications systems were developed and used for ground control of intercept aircraft—the system called GCI (ground-controlled intercept). Radio-controlled guidance of falling bombs was brought forth to enable the operator in the bomber to direct the bomb to the target. Electronic countermeasures made their appearance in the form of jamming transmitters to jam radio-communication channels and radar, navigation, and other radio aids to military operation.

At the end of World War II the military forces of the Allied nations were called upon to occupy the territories of their former enemies. The Allied signal communications staffs were usually charged with responsibility for the supervision of military and civilian communication within the occupied areas.

The military services learned well from their wartime experiences the importance of scientific research and development in all fields, including communications electronics. Advances were made toward increasing the communication capacity of wire and radio relay systems and toward improving electronic aids for navigation and for the detection of enemy forces. Measures to provide more comprehensive and more reliable communication and electronic equipment continued to be stressed in the armies, navies, and air forces of the major powers. Further impetus to these developments came from the conflict in Korea, which reaffirmed the vital importance of signal communication in the coordinated and combined operations of air, ground, and naval forces.

After mid-century, accordingly, military efforts in all the many facets of signal communication continued to intensify almost as extravagantly as during World War II. Two major additions in the U.S. Army were television and "electronic brain" equipment. The latter, in many forms of digital and analogue computers and of such data-processing devices as punch-card machines, were applied increasingly to personnel record handling and to depot and supply operations interconnected over wide areas by signal-communication networks.

Television systems proved valuable as training aids in military schools where mass instruction, especially in manual functions, was needed and where instructors were few. Such systems enabled a single instructor to teach many small classes simultaneously, each grouped before a receiver where they could watch demonstrations closely. Two-way communication systems permitted the instructor to call and question any student in any classroom and, inversely, enabled any student to put questions to the instructor. Portable television equipment in the field proved valuable for sending back to headquarters, by antenna radiation or coaxial cable, a picture of any scene of operations such as a river crossing. Equally valuable was a television camera in the hands of a forward scout or in a reconnaissance aircraft, whether piloted or remotely controlled, to scan enemy territory.

Thus signal communication, combining in itself the powers of photography, television, radar, and other instruments using the electromagnetic radiation spectrum, moved into such new areas of military communications electronics as battle area surveillance and electronic warfare devices to interfere with, or jam, enemy transmitters. In the U.S. Army, battle area surveillance activity radically augmented conventional reconnaissance methods. An electronically controlled target acquisition system, to discover enemy troops or transport on the ground or in the air, was being developed by the Signal Corps using optical, sonic, photographic, infrared, and radar equipment. The aggregate of information gathered by these devices over a wide enemy front can be electronically assembled and displayed in the headquarters where the combat commander can quickly estimate the situation and make tactical decisions.

Military signal communications in the 1960s began to employ a new technology that enabled it to attain very great ranges, coupled with high-quality service. This was communications by satellite relay. The military application by the U.S. Department of Defense followed initial experiments by the U.S. Army Signal Corps, which produced Score and Courier in 1958 and 1960 (both launched into orbit by the Air Force). An approach to an effective system supplementing the global U.S. military networks was accomplished by the two Syncom satellites developed and launched by the National Aeronautics and Space Administration in 1963 and 1964. The U.S. Department of Defense took control of the Syncom system in 1965 for communications relay through Army ground stations and Navy shipboard terminals.

SIGNAL CORPS. Organizations of this or an equivalent title have existed in the armies of many nations since the creation of the first signal corps in the Union and Confederate armies of the American Civil War.

United States.—The Signal Corps, U.S. Army, dates from June 21, 1860, when Congress authorized the post of signal officer, filled on June 27 by Maj. Albert J. Myer, assistant surgeon, who had won War Department acceptance of a simple but effective method of flag signaling (wigwag). Obtaining officers on detail, he trained a number, some of whom later served with the Confederate Army and helped establish the Confederate Signal Corps in 1862.

The provision of signal communication and related tasks of observation brought the Corps a variety of responsibilities, including weather reporting over Army wire lines from 1870 until that responsibility was transferred to the Weather Bureau in 1891, observation balloons, early Army aircraft, and Army photography. The Signal Corps made still pictures and, later, motion pictures, for many purposes, including military analysis and tactical reconnaissance; it produced and distributed all Army training films. Responsibility for electrical communications (lost during the Civil War to the civilian military telegraph organization but recovered soon after) led to wire-line construction and operations to serve Army posts and camps throughout the U.S. territorial west, and later to the provision of all communications in Alaska. The Alaska communication system, assigned to the Signal Corps in 1900, became the principal means by which civilians and government agencies in Alaska maintained rapid communication with the United States. Installed and operated by the Signal Corps, the system utilized submarine cable, overland pole lines, and radio.

Because the Signal Corps had responsibility for Army communications it was also made responsible for the use of radar and television. Army radar equipment was developed by the Signal Corps prior to World War II. Many types were used during the war, especially in aircraft detection and in gun laying. In 1946, using high-power radar designed at its laboratories at Fort Monmouth, N.J., the Signal Corps succeeded in receiving radar reflections from the moon. Television closed-circuit systems for use in Army schools and field television for use in battle area surveillance were developed (*see* Signal Communication, Military).

Signal Corps research and development laboratories worked upon a wide array of electronic aids, such as individual helmet radios for use in short-range communication with each soldier in combat, and theatre-wide area communication systems for the interconnection of headquarters by multiple routes. Such developments as these were necessary to provide the flexibility and universality needed for the command control of widely dispersed mobile forces.

To meet its responsibility for the Army strategic communications network, the Signal Corps installed and operated automatically relayed high-capacity radio and wire circuits the world over. Experimental work was done toward global communications by satellite relay, leading to the first successful satellite for communication purposes, the relatively simple Score, in December 1958, and a more sophisticated type, Courier, in October 1960.

The combat support mission of the Signal Corps included the installation, operation, and maintenance of communications within all commands down to and including the brigade. Communications within regiments and smaller units were handled by the personnel of the several arms. Field units of the Signal Corps were organized in signal operations, construction, and service battalions and in operations, construction, photographic, repair, depot, and service companies. Service companies and battalions were composed of teams, organized and equipped to perform one of the technical functions of the Signal Corps.

Unlike the signal organizations of the armies of other nations, the U.S. Army Signal Corps exercised for over a century full responsibility for development, production, and distribution of military communications equipment. But following a reorganization of the Army in 1962 these functions were removed to the newly created Army Materiel Command.

Another reorganization of March 1, 1964, eliminated the remaining Signal Corps operating organization when Signal Corps schools were transferred to the Continental Army Command, and the strategic communications function to the newly created U.S. Army Strategic Communications Command. The chief signal officer, redesignated chief of communications–electronics, retained advisory and supervisory functions only in the U.S. Army General Staff.

Other Countries.—In European armies the signal function, dating generally from the first military applications of the electrical telegraph in the mid-19th century, developed under engineer organizations. But the rapid multiplication of the means of signal communication, especially with the advent of radio early in the 20th century, took military signals from the engineers and established the function as a separate and independent organization. The commander usually serves on the general staff while directing also the many-sided operations of the signal communication system of a modern army. In Great Britain the director of signals in the War Office became head of the British Royal Corps of Signals. This Corps, which took form in 1920 from the signal service of the Royal Engineers, provides communication facilities down to brigades and forward to infantry battalions and artillery battery headquarters. In France the signal service of the army was lodged, after World War I, with the engineers until midcentury when it separated as the *Corps des Transmissions*. The commander, directly responsible to the minister of national defense, is charged with the organization and operations of the corps, the training of signal personnel and the provision of technical advice on research and development and on supply requirements. In Germany signal troops served as a separate organization, the *Nachrichtentruppe*, after 1899.

Signal communications in the U.S.S.R. operated as a general staff function directly under the Soviet war minister. Soviet signal troops serve under the ground forces along with the infantry, cavalry, and engineers. In Japan the signal section, one of the technical services of the national safety forces of the country, is represented on the general staff by the chief of the signal section. A signal company serves each army division, performing functions similar to those in the U.S. Army.

Emergency (1956); G. R. Thompson *et al.*, *The Signal Corps: the Test* (1957); G. R. Thompson and D. Harris, *The Signal Corps: the Outcome* (1966). (G. R. T.)

SIGN LANGUAGE, a means of communication through bodily movement. Organized sign language is found in many parts of the world as a kind of lingua franca (*q.v.*). Among the Plains Indians (*q.v.*) of North America, tribes with mutually unintelligible speech communicated through a system of hand movements that was understood throughout the Great Plains. Possibilities for communication were considerable; for example, the Kiowa Apache communicated with the Kiowa mainly by gestures. This sign language was comparable to that of deaf-mutes, but not identical (*see* DEAF AND HARD OF HEARING, TRAINING AND WELFARE OF). Among the Angami Nāga tribe of Assam, a remarkably flexible sign language permits real inventiveness and ingenuity on the part of the communicator, but the meaning of the signs is generally clear. Gestures formed the basis for an extended system of signs among such Australian aborigines as the Arunta.

Gestures, facial expressions, and other bodily movements facilitate communication among all peoples, kinesically supplementing and emphasizing verbal behaviour (*see* LANGUAGE: *Language in Culture: Communication*), providing traditional forms of greeting (*see* SALUTATIONS; SALUTE), and allowing for emotional expression and release of tension (*see* EMOTION). For ritualistic and theatrical aspects of sign language *see* DANCE; DANCE, PRIMITIVE; MIME; PANTOMIME.

SIGNORELLI, LUCA (LUCA DA CORTONA, originally LUCA D'EGIDIO DI VENTURA DE' SIGNORELLI) (*c.* 1445/50–1523), Italian painter, the most powerful exponent of the nude before Michelangelo, was born in Cortona, Umbria, probably between 1445 and 1450. He was first recorded as a painter in 1470, but it is very likely that he was a pupil of Piero della Francesca, along with Perugino, in the 1460s. The first certain surviving work by him is a fragmentary fresco, now in the museum at Città di Castello, which he finished in Nov. 1474. This shows a strong influence from Piero della Francesca, and the style is responsible for the attribution to Signorelli at this date of several other pictures, including the beautiful Madonna in Christ Church library, Oxford. His first signed work was a processional banner with a Madonna on one side and a Flagellation on the other; these are now in the Brera, Milan, as separate pictures. They still show links with the style of Piero, but the dominant influence is that of Florence, and especially that of the Pollaiuoli, which suggests that Signorelli visited Florence in the 1470s. The scientific naturalism represented by the Pollaiuoli now becomes the principal feature of Signorelli's style. In 1479 he was elected to the council of 18 in his native Cortona and for the rest of his life he was active in politics.

About 1483 he went to Rome, for the "Testament of Moses" fresco in the Sistine chapel is unanimously attributed to him; yet his name does not occur in the only two documents—of 1481 and 1482—known to us. It is likely that his friend Perugino got him the commission to help complete the cycle. By this date his style was fixed and his interest in dramatic action and the expression of great muscular effort mark him as an essentially Florentine naturalist working outside Florence. The altarpiece for Perugia cathedral, of 1484, shows the same qualities. Between 1497 and 1498 he was at work on a fresco cycle of scenes from the life of St. Benedict in the monastery at Monteoliveto Maggiore, near Siena, but these are hardly more than a prelude to his masterpiece, the frescoes of the "End of the World" and the "Last Judgment" in the chapel of S. Brizio in Orvieto cathedral. A small part of the ceiling had been painted by Fra Angelico in the 1440s, and he had determined the subject by painting the "Christ in Judgment" over the altar. On April 5, 1499, Signorelli was commissioned to complete the ceiling and it was not until April 27, 1500, that he received the more important commission to paint the walls. At this moment Italy was in turmoil, partly because of the incursions of the French armies and partly because of the preaching and death of Savonarola, who seemed to have predicted the French invasion as a judgment. The French had actually by-passed Orvieto on their way south, and the completion of the frescoes was therefore in the nature of a thanksgiving. It also explains the grim and terrible treatment of a subject well suited to Signorelli's genius. The large scenes on the walls represent the last days of the world, with the portents of doom followed by the appearance of Antichrist and the false miracles worked by him before his final destruction. In the frescoes nearer to the altar we see the next stages, the "General Resurrection" and the "Last Judgment," "Heaven" and "Hell." The "Judgment" itself is represented only by the small figure of Christ over the altar, painted by Angelico. Behind the altar are a Dantesque "Hell" (with the classical figure of Charon and the River Styx) and a part of the "Blessed in Heaven." Signorelli had little sense of colour, but here his greenish and

"THE CONDEMNED IN HELL," A DETAIL FROM ONE OF SIGNORELLI'S FRESCOES IN THE CHAPEL OF S. BRIZIO, ORVIETO, ITALY

purple devils add to the horror induced by the strained poses and the anatomical details in the resurrected and decayed bodies.

The Orvieto frescoes reach a level that he never again achieved, although he lived nearly 20 years after he received the final payment on Dec. 5, 1504. He was in Florence in 1508 on official business as prior of Cortona and he went to Rome at about this time, and again in 1513, but the new generation—Michelangelo and Raphael—had now won all the commissions and Signorelli returned to his less sophisticated Umbrian clientele. Most of his later works betray the hands of his numerous assistants, but among his better works are the altarpiece in the National gallery, London (1515), the "Deposition" (1515/16) in Sta. Croce, Umbertide, and the "Assumption" and "Immaculate Conception" begun in 1519 and 1521 (both in the Museo Diocesano, Cortona). One of his finest works, the "Pan" formerly in Berlin, was destroyed in World War II. He died in Cortona on Oct. 16, 1523.

SIGURD, the name of two kings of Norway.

SIGURD I (*c.* 1090–1130), nicknamed Jorsalafar (Jerusalem-farer), king from 1103 to 1130, an illegitimate son of Magnus II Barfot, succeeded to the throne, together with his elder and younger brothers Eystein and Olaf, on Magnus' death. About 1107 Sigurd sailed for the Holy Land, first visiting England, France, Spain, and Sicily. He bathed in the Jordan and was lavishly entertained by Baldwin I, king of Jerusalem. Leaving his ships at Constantinople, as a gift to the emperor Alexius I, he reached Norway (1110) overland. After the deaths of Olaf (1115), who never ruled in fact, and of Eystein (1122), Sigurd was sole ruler until his own death in 1130. He strengthened Norway's defenses and placed the Church on a secure footing by introducing tithes. In his latter years he became mentally unbalanced.

SIGURD II (1134–1155), nicknamed Munnr (Mouth), was an illegitimate son of Harald IV Gille, on whose death (1136) he and Harald's legitimate son Ingi, both minors, were proclaimed joint kings. Their supporters withstood other pretenders to the throne until, in 1142, they were joined by Eystein, who claimed also to be a son of Harald and was given a third of the kingdom. Sigurd was killed in 1155 by the supporters of Ingi. (G. T.-P.)

SIGURD, a figure in Germanic heroic literature: *see* SIEGFRIED.

SIGURDSSON, JÓN (1811–1879), Icelandic statesman and scholar who, as leader of the Patriotic Party, worked tirelessly to obtain some degree of self-government for his country. He was born in the west of Iceland on June 17, 1811. After studying classical philology and ancient history, and later political theory and economics at the University of Copenhagen (1833–35), he worked (1835–48) on the Arnamagnean collection of Icelandic manuscripts and was thereafter, until his death, secretary of the Arnamagnean Commission. Throughout his life he edited, either alone or in cooperation with others, a series of ancient texts, including a number of sagas (in *Islendinga Sögur*, vol. i and ii, 1843–47), the *Edda Snorra Sturlusonar* (1848–52), *Lovsamling for Island*, 17 vol. (1853–77), *i.e.*, a collection of Icelandic law, and the first volume (1857) of the series *Diplomatarium Islandicum*.

One of the greatest of Icelandic scholars, Sigurdsson achieved equal distinction as a statesman. Working in Copenhagen, he became involved in the discussions which preceded the authorization (1843) by the Danish king Christian VIII of the revival, as an advisory body, of the *Althing*, the ancient legislative assembly of Iceland. Elected a representative for its first meeting (1845), Sigurdsson rapidly became one of the most influential members of the *Althing* and was for many years speaker of the lower house. On the establishment (March 1848) of representative government in Denmark, Sigurdsson immediately demanded virtual self-government for Iceland. But at a national assembly held at Reykjavík (1851) it was made clear that the Danes would grant to Iceland only the limited autonomy allowed to the various districts of Denmark. Acceptance of such terms would have constituted Iceland a mere province of Denmark, and Sigurdsson, supported by the majority of delegates, categorically rejected them.

For the following 20 years Sigurdsson and his party continued to reiterate their demands. He also sought to improve his country's economic situation, and partly as a result of his agitation the Icelandic trade was finally freed from Danish monopoly and opened to all nations in 1854. He also encouraged the development of modern methods of agriculture and fisheries. The crown of Sigurdsson's achievements came in 1874, the one-thousandth anniversary of the settlement of Iceland, when King Christian IX granted Iceland a constitution. The *Althing* was now to control Icelandic finance, and to share legislative power with the crown. Complete home rule was not won until the 20th century, but this preliminary step was described by Sigurdsson as "a good beginning." Sigurdsson died in Copenhagen on Dec. 7, 1879, and was buried at Reykjavík.

See T. Johnson, *Jon Sigurdsson, the Icelandic Patriot* (1887); P. E. Ólason, *Jón Sigurtsson* (1940). (T. J.)

SIIRT, capital town of an *il* (province) of the same name in southeastern Anatolia, Turkey, lies on the Buhtan River in the southeastern foothills of the Taurus Mountains, and 95 mi. (153 km.) E of Diyarbakir. Pop. (1960) 22,944. Before the disintegration of the Ottoman Empire Siirt was an important trade centre of a large region which included northern parts of Syria and Iran. Its economic importance is now local. The chief industrial activity is the manufacture of blankets, which are well known throughout Turkey. The town is linked by road with Diyarbakir, Cizre, and Bitlis.

SIIRT IL extends from the southeastern foothills of the Taurus in the northeast to the Tigris Valley in the southwest. Area 4,447 sq.mi. (11,518 sq.km.). Pop. (1960) 232,243. It is drained by several tributaries of the Tigris, the chief being the Buhtan and the Garzan. The climate is severe with heavy snowfall in winter. The mountains are well forested, whereas the foothills and plains in the south have steppe vegetation. The cultivation of cereals and livestock produce are the chief sources of income. In the southwest is the Raman oil field, and oil is refined at Batman nearby. (N. Tu.; S. Er.; E. Tu.)

SIKANG (HSI-K'ANG SHENG), a former Chinese province made up of parts of western Szechwan and eastern Tibet in 1928 and dissolved in 1955. Area 204,247 sq.mi. (529,000 sq.km.); pop. (1953) 3,381,064. Chinese claims to controlling all Tibet vary both in age and degree of control, but at least as far back as 1751 the Ch'ien-lung emperor established his Chinese commissioners in Lhasa with full political power over the Dalai Lama. In the late 19th century, the British authorities in India contested this greatly weakened control, and in 1913 supported a Tibetan independence movement, urging that China divide the area into an Inner and Outer Tibet with a consequent division between Chinese and British influence. Although China did not accept these changes, in 1928 eastern or Inner Tibet ("Kham" in Tibetan) was split into Ch'ing-hai and Sikang provinces, while Outer Tibet was declared a special territory within China. Under the Chinese People's Republic the eastern half of Sikang, from Ya-an, the former capital, near the Ta-tu River west to Pa-tang on the Chin-sha or upper Yangtze, was incorporated into Szechwan province, July 1955, while the western half (Chamdo) was placed back in Tibet or Hsi-ts'ang province.

Sikang averages 13,000 ft. above sea level, a vast plateau marked by jagged snow-covered ranges, canyons, coniferous forests, streams, and lakes. Through it run the upper courses of the Yangtze with several of its tributaries, and the Mekong, Salween, and Brahmaputra rivers. Its highest known peak, Minya Konka, rises 24,891 ft. above sea level. The dominant economies are subsistence farming of barley, dry rice, potatoes, and a few vegetables on the narrow valley floors and stream terraces, and herding on the plateaus. Horses, wool, furs, musk, medicinal plants, gold, and asbestos have been the main products exchanged for brick tea, salt, tobacco, cloth, and other consumer goods; coal and rich iron ore deposits are found in the eastern parts. The Chinese built two heavy motor roads into the area, largely along ancient caravan trails.

See also CH'ENG-TU. (TE. H.)

SIKAR, a town in Rajasthan, India, and the administrative headquarters of the district of the same name, lies about 65 mi. (105 km.) NW of Jaipur city on the Western Railway. Pop. (1961) 50,636. About seven miles to the southeast of the town is a ruined temple, which is reputed to be many centuries old.

SIKAR DISTRICT has an area of 3,027 sq.mi. (7,840 sq.km.) and a population (1961) of 820,286. The soil is mainly sandy; in the eastern part of the district sandy loam soil is also found. The average annual rainfall is about 15 in. (381 mm.). The chief crops are jowar, bajra, barley, and gram. Other important towns are Fatehpur, Lachmangarh Sikar, Ramgarh, Neem-Ka-Thana and Sri Madhopur.

There is a cotton ginning factory at Neem-Ka-Thana and *khadi* (homespun cotton cloth) is made at Reengus, which is also an important junction on the Western Railway. (S. M. T. R.)

SIKELIANOS, ANGELOS (1884–1951), one of the leading modern Greek lyrical poets, was born on the island of Leukas.

His first important work, the *Alafroiskiotos* was published in 1909, and revealed his lyrical powers. It was followed by a group of outstanding lyrics. His next period was introduced by the philosophic poem *Prologos tes Zoes* ("Prologue to Life"; 1917) and includes the long works *Meter Theou* ("Mother of God") and *Pascha ton Hellenon* ("The Greek Easter"), culminating in the *Delphikos Logos* ("Delphic Utterance"; 1927). The Greek tradition and the national historic and religious symbols are here given a mystic turn and a universal significance. In the 1930s and 1940s there appeared a second group of lyrics, which display the full power of Sikelianos' art. They express in rich and incisive language and with forceful imagery the poet's belief in the beauty and harmony of the world. The tragedies of Sikelianos (*Sibylla, Daedalus in Crete, Christ in Rome, The Death of Digenis* and *Asklepius*, which are introduced by the long dramatic poem *The Dithyramb of the Rose*) are more notable for their lyric than their dramatic qualities.

In his mature works Sikelianos is fulfilling in poetry the aspirations of the "demotic movement" of the 1880s, which sought to combine Greek tradition with western thought, and to introduce as a consciously literary language the idiom of the people. Although occasionally the power of his inspiration drives him to grandiloquence which blunts the poetic effect of his work, some of his finer lyrics are among the best in 20th-century western literature.

Sikelianos died at Athens, June 19, 1951.

See P. S. Sherrard, *The Marble Threshing Floor; a Study in Modern Greek Poetry* (1956). (Ce. A. T.)

SIKHISM, an Indian religion combining Islamic and Hindu beliefs, founded in the late 15th century A.D. by Nanak, the first guru (teacher). The word "Sikh" is derived from the Sanskrit *shishya* ("disciple"). Sikhs are disciples of their ten gurus, some of whose writings are compiled in the Granth Sahib, the Sikh sacred book (*see* GRANTH). An act of the Indian legislature defines a Sikh as one who "believes in the ten gurus and the Granth Sahib." The Sikhs, approximately 8,000,000 in number, are mainly concentrated in East Punjab (*see* PUNJAB) where in the 19th century they created a powerful state under Ranjit Singh before the British took over the country. The majority of them belong to agricultural tribes of Indo-Scythian stock. Small communities of Sikhs live also in the United Kingdom, Canada, the United States, East Africa, Burma, Malaya, and Hong Kong.

The Ten Gurus.—Muslims began invading India in the 8th century A.D. By the 15th century they had conquered the whole of northern India and converted to Islam large numbers of Hindus, particularly in the Punjab and Bengal. This impact of Islam on Hinduism generated movements aiming at a compromise between the two faiths. Nanak (1469–1539), the founder of Sikhism, was the son of a Hindu revenue official of a village called Talwandi now in West Pakistan. From an early age he began to seek the company of wandering hermits. Although he took occasional employment, married and reared a family, he remained preoccupied with spiritual matters. At the age of 30 he gave up other pursuits and became a teacher. The main point of his teaching was to emphasize the need of a rapprochement between Hinduism and Islam. He was influenced by the teachings of the exponents of *bhakti* (the devotional movement), notably Kabir (*q.v.*), and by the Muslim Sufis (*see* SUFISM). He rejected many of the cherished beliefs and practices of Hinduism and accepted instead those of Islam. He was a monotheist, opposed to the worship of idols, and a strong critic of the caste system. He advocated the repetition of *nam* (name of the Lord) as a means to salvation. Nanak traveled extensively all over India and through the Arab countries of the Middle East.

Nanak chose as his successor a disciple named Angad (1504–52), who traditionally invented the Gurmukhi script (*see* PANJABI LANGUAGE) and built *gurdwaras*, as Sikh temples are called, from which the teachings of the founder could be propagated. On his death, Angad chose a disciple, Amardas (1479–1574), to be the third guru. Amardas nominated his son-in-law, Ramdas, to be the fourth, and thereafter the gurus came from one family. Ramdas (1534–1581) had a large tank dug, around which his son Arjan (1563–1606) built the city of Amritsar (*q.v.*), making it a place of pilgrimage for the Sikhs. Arjan compiled the Granth by collecting the writings of his predecessors and of some Hindu and Muslim saints whose teachings agreed with those of the gurus, and adding to them some hymns of his own. He also built many temples, and for the purpose received offerings from his followers. The Mughal emperor Jahangir, perturbed by Arjan's influence, had him arraigned on a charge of nonpayment of taxes and of vilifying Islam. He was tortured and died on May 30, 1606, at Lahore.

After the execution of Arjan the Sikhs began to change from a pacifist to a militant sect. Arjan's son, Hargobind (1595–1644), began to drill his followers and equip them with arms, as a result of which he was arrested and kept in Gwalior fort for some time. On his release he resumed his activities and fought a few minor engagements with the Mughals. Hargobind's grandson Har Rai (1630–1662), followed by his young son Harikrishen (1656–1664), made no significant contribution to the development of the Sikh religion. The ninth guru, Hargobind's son Teg Bahadur (1621–1675), who organized Hindu resistance against the bigotry of the Mughal emperor Aurangzeb, was executed in Delhi on Nov. 11, 1675.

Teg Bahadur's son, Gobind Rai (1666–1708), took the final steps in militarizing the Sikhs. On the Hindu New Year in 1699 he assembled his followers at Anandpur, founded by his father, in the foothills of the Himalayas, and initiated five of them as members of a fraternity which he named the Khalsa ("pure"): they drank *amrit* (nectar) out of the same bowl (though they all came from different castes), received new names with the suffix Singh ("lion"), and swore to keep the five K's: to wear long hair (*kesh*), a comb (*kangha*) in the hair, soldier's shorts (*kachkha*), a steel bangle (*kara*) on the right wrist, and a sabre (*kirpan*). After initiating the five, the guru was in his turn initiated by them and renamed Gobind Singh. At the end of the initiation the guru hailed his new converts with the words *Wah Guru ji ka Khalsa, Wah Guru ji ki Fateh*—"The Khalsa are the chosen of God, victory be to God."

In the days following, some 80,000 persons were initiated into the Khalsa fraternity. Many Sikhs, however, known as Sahajdharis (those who take time to adopt the new faith), preferred to remain clean-shaven. The division between the Khalsa and the Sahajdhari continues to this day.

Gobind Singh lost all his four sons in his lifetime and declared the succession of gurus at an end, investing the Granth, of which he produced the final edition, as the immortal guru of the Sikhs. His own hymns were compiled separately in a volume called the *Dasam Granth*, which is not given the sanctity accorded to the Granth Sahib. Gobind Singh was assassinated on Oct. 7, 1708, while he was in Nanded in Hyderabad state.

Sikh Rise to Power.—Before his death Gobind Singh charged a Hindu ascetic, Lachhman Das (1630–1716), to avenge the tyranny perpetrated by the Mughals on the Sikhs. Lachhman Das, who took the name Banda Singh Bahadur at his initiation, roused the non-Muslim peasantry and in a series of whirlwind campaigns destroyed the Muslim landed class in southern Punjab. After eight years of defiance Banda was starved to surrender, and along with 700 of his followers he was executed in Delhi on June 19, 1716.

For many years following Banda's execution the Sikhs were savagely persecuted by the Muslim governors of the Punjab. But the situation eased with the invasion of the Persians under Nadir Shah in 1738–39, followed by the series of incursions of the Afghans led by Ahmad Shah Durrani, who in 1761 defeated the Marathas at Panipat. The Sikhs, who had kept out of the way of the invader, filled the vacuum he left under their remarkable leaders, chiefly Kapur Singh and Jassa Singh Ahluwalia. They divided the Sikh forces into 12 *misls* or militias with their own spheres of operations. The strength of the *misls* varied from 20,000 horsemen of the most powerful, the Bhangis of Gujrat, to a few hundred of the smaller ones. The *misls* built chains of forts and levied *rakhi* (protection money) from towns and villages. In 1761 Jassa Singh Ahluwalia occupied Lahore for a short while and struck coins in the name of the *misl* confederacy. In 1765, when the

Bhangis took Lahore, the power of the Sikh *misls* extended from the Indus in the west to the Ganges in the east, and from the Himalayas in the north to the desert wastes of Sindh in the south.

The *misls* did not retain their cooperative character for long. As soon as they had dispossessed the Mughals, they began to fight among themselves, until Ranjit Singh of the Sukarchakia *misl* absorbed the others and created a unified Sikh State.

The Sikh Empire.—Ranjit Singh (*q.v.*) became chief of the Sukarchakias at the age of 12. With the help of his mother-in-law, Sada Kaur, widow of a chieftain of the Kanahya *misl*, he captured Lahore in the summer of 1799 and proclaimed himself maharaja of Punjab. Sada Kaur also helped him to take Amritsar and destroy the *misls* north of the Sutlej as well as the petty Muslim and Hindu kingdoms of the Punjab plains and hills. Ranjit Singh's ambition to extend his power over the rest of the Punjab was curbed by the English, who in 1809 forced him to sign the Treaty of Amritsar and to accept the Sutlej River as his eastern boundary. He captured Multan in 1818 and Kashmir in 1819. In 1822 he began to modernize his army by employing officers of Napoleon's disbanded army to train his troops. In 1823 he defeated the Afghans and planted his flag on the ramparts of Peshawar; Sikh rule was firmly established there in 1834. His Dogra underlord, Gulab Singh, extended the Punjab's frontiers beyond Ladakh into little Tibet (Baltistan). In 1638 Ranjit Singh signed a tripartite treaty with the British and the exiled Afghan Shah Shuja for a joint invasion of Afghanistan.

Dissolution of the Sikh Empire and the Anglo-Sikh Wars.—After the death of Ranjit Singh, the Sikh kingdom rapidly disintegrated into anarchy. His eldest son and successor, Kharak Singh, died of drink, and Kharak Singh's son, Naonihal Singh, was killed in an accident on the same day (Nov. 5, 1840). Naonihal Singh's wife, Maharani Chand Kaur, ruled for a few months till she was ousted (and later murdered) by Ranjit Singh's second son, Sher Singh. Sher Singh ruled for two years till his assassination on Sept. 15, 1843. Ranjit Singh's youngest son, Dalip Singh, was proclaimed maharaja with his mother, Maharani Jindan, as queen regent, but power in fact passed into the hands of the army, which began to dictate to the maharaja and his ministers.

The English, apprehending hostilities, began to move their forces to the Punjab frontier, and there followed what are known in English history as the Sikh Wars of 1845–46 and 1848–49. For these, *see* SIKH WARS. After the Sikh defeat, the Punjab was annexed to British India. Maharaja Dalip Singh, granted a pension, left India to reside in England, and died on Oct. 22, 1893.

Sikhs Under British Rule.—After three years, the three-man Board of Administration set up to rule the Punjab was abolished and Sir John Lawrence became chief commissioner. Having seen the fighting quality of the Sikhs, he threw open recruitment to them, a policy which paid dividends as the Sikhs helped the British to quell the Indian Mutiny of 1857. After the Mutiny, the proportion of Sikhs in the British Army in India was increased. New regulations requiring Sikh soldiers to observe the outward symbols of the Khalsa faith (*i.e.*, keeping their hair and beards unshorn) were largely responsible for retaining the separate identity of the Sikhs.

After the British annexation several movements, religious, social, and political, occurred among the Sikhs. The Nirankaris aimed at reforming religious ritual. The Namdharis or Kukas under Ram Singh sought to reestablish Spartan traditions of the early Khalsa and restore Sikh rule. In January 1872 the Namdharis clashed with the police and 66 of them were apprehended and blown off from cannons at Maler Kotla; Ram Singh was exiled to Rangoon where he died in 1885. The Singh Sabha movement which came into prominence at the turn of the century was essentially educational and literary. It enjoyed the patronage of English administrators, with whose collaboration Sikh schools and colleges were founded in different parts of the Punjab. The movement stimulated interest of European scholars in Sikhism, the most notable of them being M. A. Macauliffe who produced a six-volume study of Sikh religion (1909). Among the Sikh scholars associated with the movement was the poet-philosopher Vir Singh (1872–1957).

Anglo-Sikh collaboration was closest during World War I. Recruitment for active service was considerably higher among the Sikhs than among any other Indian community, and Sikhs fought with distinction in France, Africa, and the Middle East. Differences arose during the war, however, between the Sikhs and the British government. Sikh settlers in British Columbia and California who were subjected to discrimination formed a revolutionary organization known as the Ghadr ("Mutiny"). Many returned to India and for several months of 1915 carried on terrorist activities in central Punjab. The Ghadrites were crushed. Immediately after the war Sikhs clashed with the government over the control of their *gurdwaras*. The government supported the hereditary Mahants who were in possession. A group of radicals formed the party known as Akali ("immortals") to take over the *gurdwaras*. More than 30,000 men were imprisoned in the Akali movement, which lasted from 1922 to 1925. In that year the Sikhs Gurdwaras Act was passed, handing over all historic shrines to a 160-man elected body known as the Shiromani Gurdwara Prabandhak Committee. During World War II the Sikhs again cooperated with the British, but with considerably less zeal than they had done before. An influential group belonged to the Indian National Congress and a substantial proportion of the Japanese-sponsored Indian National Army was composed of Sikhs.

Sikhs in Independent India.—The relinquishment of power by Britain was accompanied by the partition of the country. The western part of Punjab became Pakistani territory, the eastern part Indian. The Sikhs left in Pakistan (about 2,500,000) moved to India and in turn ejected Muslims living in East Punjab. This mass exchange of populations was accompanied by extreme violence resulting in heavy loss of life. Most of the refugee Sikhs were rehabilitated in East Punjab. In many districts bordering on West Pakistan the Sikhs came to form a majority of the population. They also spread into the Terai region of Uttar Pradesh, Rajasthan, and Madhya Pradesh. The scale of compensation for refugees was so low as to cause severe hardship. A sense of grievance against the administration was generated, and the demand for an autonomous Sikh state gathered momentum. In March 1966 the Congress Party agreed to create in Punjab a separate Punjabi-speaking state in which Sikhs would constitute about 55% of the population. (*See* PUNJAB [INDIA].)

Religion and Way of Life.—The Sikh religion is an amalgam of the Muslim faith and Hinduism, simply and clearly expressed in the Panjabi language. There is one God, who is not represented by idols or images. Man should serve him by leading a good life in obedience to his commands, and by prayer, in particular by repeating the name of God, until, after his soul has passed through various existences by transmigration, he ultimately becomes one with God. Religious rites and customs which are meaningless formalities, such as bathing in "holy" rivers and making offerings to the dead, are to be rejected. Practices which injure health, such as drinking and smoking, are forbidden. There is no professional priesthood, all adults of either sex being eligible to carry out religious ceremonial, although in big Sikh communities there are professional singers and readers of the Granth. The Sikh religion is not ascetic, and the ideal is married life within normal human society. Although Sikhism officially deprecates the caste system and pronounces the equality of all men before God, it has been difficult in practice to escape from caste divisions, especially where marriage is concerned. The relationship between Sikhs and Hindus is in fact close, and Hindus in the Punjab honour the gurus.

The Sikh place of worship is the *gurdwara*, in which, in the most prominent position, is a copy of the Granth that is treated with great honour. The chief *gurdwara* is the Havimandir (known as the Golden Temple) at Amritsar, founded by Guru Arjan, several times destroyed, and finally rebuilt by Ranjit Singh. Sikh worship consists largely of reading from the Granth. Sikhs keep the Hindu festivals by performing ceremonies in their *gurdwaras*, and they also celebrate festivals on their own holy days, such as the birthdays of some of the gurus, by taking the Granth in procession through the streets. Sikh boys and girls undergo the initiation ceremony of the five K's at the age of puberty and boys take the additional name of Singh (though not all persons named Singh are Sikhs). The corresponding name for Sikh women is Kaur.

Sikhs make excellent farmers, soldiers, and mechanics. The proportion of literacy is higher among them than among any of the other major communities of India. Apart from the Khalsa College at Amritsar there are a number of medical, engineering, and technical institutes affiliated to the universities of the Punjab, Delhi, and Bombay.

SIKHOTE-ALIN, a mountain complex of the U.S.S.R., is located in the Soviet Far East, along the coasts of the Sea of Japan and the Tatar Strait. The chain lies in the Primorskiy (Primorski; Maritime) Kray and Khabarovskiy (Khabarovsk) Kray of the Russian Soviet Federated Socialist Republic. It is orientated northeast–southwest for about 800 mi. (1,300 km.) from the lower Amur to Vladivostok. It is bounded by the sea to the southeast and the tectonic trench of the Ussuri Valley to the northwest. The Sikhote-Alin was formed in the Mesozoic folding period, but was much affected and uplifted in the Alpine period. The area is bounded by major fault lines and there is a general tilt to the west. The relief is complex, with eight main ranges rising to a maximum height of 6,818 ft. (2,078 m.) in Mt. Tardoki-Yani. The general westerly tilt means that the watershed lies fairly close to the coast and the main rivers, Khungari, Anyuy, Khor, Bikin, and Iman drain to the Ussuri-Amur. Although the highest, rounded summits are bare, most of the mountains are forested with pine, larch, fir, and birch. The lower slopes toward the Ussuri are densely covered with "jungle" of eastern deciduous species. Although a wide range of minerals has been found in the Sikhote-Alin, few are exploited, except coal in the south. The whole area is thinly populated. (R. A. F.)

SIKH WARS, two campaigns fought between the Sikhs and the British, which resulted in the conquest and annexation by the British of the Punjab in northwestern India.

The Sikh state in the Punjab (*q.v.*) was built up into a formidable power by Maharaja Ranjit Singh (*q.v.*; ruled 1792–1839). It extended from the Sutlej River to the Afghan hills and from Multan to the Kashmir mountains and Tibet. Its strength rested on its Western-trained army with a formidable train of artillery. Within six years of Ranjit's death, however, the state government broke down in a series of palace revolutions and assassinations. There were four rulers, the last a boy. (*See* SIKHISM.) The army got out of hand and organized itself in *punches* (committees). Finally the regent, Maharani Jindan, and her minister, Lal Singh, determined to invade British India under the pretext of forestalling a British attack.

The First Sikh War (1845–46).—Such were the conditions in the Punjab when the first Sikh War broke out in 1845. Relations with the British had already been strained by the refusal of the Sikhs to allow the passage of British troops through their territory during the first Afghan War (1838–42), and Sikh suspicions were heightened by Lord Ellenborough's defeat of the Gwalior Army in 1843. British troops were concentrated at Ferozepur, Ludhiana, and Ambala, so that neither side was taken by surprise. British forces amounted to 40,000 men with 94 guns as compared with the Sikh regular army of about 60,000 men with several hundred guns (some estimates are higher). With due allowances, the two forces were not unequally matched. The British had far greater reserves, but an early Sikh success might have roused all north and central India. The British Army possessed the advantage of unified leadership and confident belief in itself, whereas the Sikhs were divided, hesitant, and depressed.

The Sikh Army crossed the Sutlej on Dec. 11, 1845, and threatened Ferozepur. British preparations, however, were complete, and their main army marched 16 mi. from Ambala on the 12th and reached the neighbourhood of Ferozepur by the 18th. In the two battles at Mudki and Ferozeshah, the Sikhs under Lal Singh were thrown back across the Sutlej. A second Sikh army under Tej Singh failed to seize the opportunity of falling on the British when the troops were exhausted on the morning after the Ferozeshah battle. The losses were heavy on both sides, but the result was not decisive. In January 1846 the Sikhs made a dash for Ludhiana but were repulsed at Aliwal on Jan. 28. On Feb. 10 Sir Hugh (later Field Marshal Viscount) Gough, his heavy artillery having arrived, attacked and routed the Sikhs at Sobraon. The collapse of a bridge of boats caused the breakup of the Sikh Army and the Treaty of Lahore was concluded March 9.

By the treaty the Jullundur region and Jammu and Kashmir were ceded to the British and an indemnity of £500,000 was exacted. The Sikh Army was reduced to 20,000 infantry and 12,000 cavalry, and a British resident was installed at Lahore. Annexation was rejected on account of the martial nature of the people. For nearly two years the resident, Sir Henry Lawrence, successfully controlled the government, with his powers enhanced by another treaty signed at Bhairowal in December 1846. But the Sikhs remained restless and unconvinced that they had been finally defeated.

The Second Sikh War (1848–49).—Within months of Lawrence's departure on leave, Dewan Mulraj, the Sikh governor of Multan, rose against the Lahore government (April 1848). The governor general, Lord Dalhousie, was advised to wait until the cold weather before suppressing him; as a result the Sikh Army joined the insurgents, thus turning a local rising into a national war. Gough, again in command, crossed the Ravi on Nov. 16. The Sikhs were led by Sardar Sher Singh Attariwala. Two bloody but inconclusive battles at Ramnagar and Chillianwalla led to the decisive Battle of Gujrat on Feb. 21, 1849, when Gough, who had been much criticized for his preference for frontal attack to cannon fire, at last gave his artillery full scope. The Sikh leaders surrendered on March 12 and the Punjab was then annexed. The losses at Chillianwalla were so great (2,446 casualties, 4 guns, 3 colours) that Sir Charles Napier was appointed to supersede Gough, but Gujrat was won before Napier could arrive.

See J. D. Cunningham, *History of the Sikhs*, 2nd ed. (1853; rev. ed. by H. L. O. Garrett, 1919); Sir C. Gough and A. D. Innes, *The Sikhs and the Sikh Wars* (1897). (T. G. P. S.)

SI KIANG: *see* HSI CHIANG.

SIKKIM, a country in the eastern Himalayas and a protectorate of the government of India, is bounded on the west by Nepal, on the north by Tibet, on the east by Bhutan, and on the south by India. It has an area of 2,828 sq.mi. (7,325 sq.km.). The capital is Gangtok.

Physical Geography.—Sikkim is a mountainous country consisting of part of the main chain of the Himalayas and of ranges projecting southward and gradually lessening in height. Kangchenjunga (*q.v.*) in the north rises to more than 28,000 ft. (8,500 m.), and in the south the outer hills are about 700 ft. (215 m.) in height. Between these ranges the country is split up into mountain ridges and deep valleys where every type of climate from arctic to subtropical can be found. Accordingly the vegetation is very diverse. Below the line of eternal snows (17,000 ft. [5,100 m.]) to 12,000 ft. (3,600 m.) is grassland for cattle; down to 9,000 ft. (2,700 m.) are forests. On the slopes between 4,000 and 7,000 ft. crops are grown. In the valley bottoms there is luxuriant tropical growth. The chief river is the Tista, which is formed by the confluence of the Lachen and the Lachung in the north of Sikkim. Rainfall is heavy, the annual average varying from about 130 in. (3,300 mm.) at Gangtok to about 30 in. (760 mm.) in the more sheltered areas in the north. The abundant vegetation includes many types of flowering plants, orchids, and rhododendron. There are also a large number of species of moths and butterflies.

History.—The Lepchas are thought to be the earliest inhabitants of Sikkim. Their numbers began to diminish after the Tibetans started to colonize Sikkim at the end of the 16th century. Definite control by the Tibetans was acquired during the first half of the 17th century when several lamas fled from the Chinese in Tibet. They made Buddhist lamaism the state religion of Sikkim and established a government under a Tibetan king (1642), from whom the succeeding line of maharajas claimed descent.

Sikkim remained a Tibetan dependency until the end of the 18th

century, when British expansion in India changed the situation. Under a British-Nepalese treaty (1816) Nepal was obliged to return the Terai or submontane portion of Sikkim to the Sikkimese. During the war between Nepal and Sikkim (1834–35) Britain intervened again and in 1839 obtained the site of Darjeeling from Sikkim. Ten years later, after much friction between the British and the Sikkimese, Britain seized the Terai and some of the outer hills. The trouble resulting from this measure was settled by a treaty which Britain forced upon Sikkim in 1861. This treaty established British suzerainty over Sikkim, at least in the British view, though this was not shared by the Tibetans, who proceeded to engage in official activities in Sikkim. In 1888 a British military expedition drove the Tibetan army out of Sikkim and pursued it into the Chumbi Valley in Tibet. The Chinese—suzerains of Tibet—ordered their resident in Lhasa to make peace, but disagreement regarding suzerainty over Sikkim delayed a treaty until 1890, when Sikkim's borders were finally defined and China recognized British control over Sikkim's internal administration and foreign relations. For this purpose, a British political officer was appointed to assist the maharaja. In 1893 a supplementary treaty between China and Britain, relating to trade, communications, and pasturage, gave the British special rights in Sikkim and in Tibet but was not recognized by the Tibetans.

When India obtained independence in 1947, it succeeded to British rights in Sikkim under a temporary standstill agreement. By this time the maharaja had introduced minor social reforms and political liberties. Essentially, however, his rule and that of the big landowners in their areas were autocratic. The peasants were helpless and exploited. Dissatisfaction with the system caused such civil disorders between 1947 and 1949 that the maharaja had to call for Indian assistance, and in June 1949 Sikkim had again become a protectorate, this time of India. An agreement of 1950 entitled India to handle Sikkim's defense, communications, and foreign affairs. With the approval of the Indian government several political parties continued to agitate for reforms, which were gradually being granted. In the meantime, the government was proceeding with the modernization of the cultural and economic life of the people, in particular the construction of motorable roads and hydroelectric power plants.

Population.—At the 1961 census the population of Sikkim was 161,080, compared with 137,725 at the 1951 census. Most of the increase was accounted for by the Nepalese, who form about three-quarters of the population, the minority groups—Bhotias and Lepchas—showing virtually no increase at all. The communities do not intermarry since the Nepalese are mostly Hindus and the Bhotias and Lepchas Buddhist. The Nepalese live as cultivators in the middle altitudes; the Bhotias are mainly graziers in the high altitudes; the Lepchas usually live in the remotest valleys. There are no towns and the villages are widely scattered. In 1961 Gangtok, which lies on the main trade route between India and Tibet, had a population of 6,848.

Government and Social Conditions.—An Indian-appointed dewan (quasi prime minister) shares power with the maharaja who remains supreme ruler. The maharaja is assisted by an executive council and by a state council whose 20 members are partly elected and partly appointed by the maharaja. The subjects which the members of the state council are permitted to discuss are restricted, and the maharaja retains a veto over all their decisions. In the general elections held in 1960 the National Party (which has the maharaja's support) won seven of the 14 elective seats, the Nepalese-supported National Congress four seats, and the State Congress three seats. An election scheduled for the end of 1962 was postponed as a result of the emergency caused by China's invasion of India. Instead a People's Consultative Committee was formed, in which all population groups and political parties were represented.

In Sikkim there were in the early 1960s almost 100 government schools and about 50 government-aided schools, with approximately 10,000 pupils. Medical services included 4 hospitals and 20 dispensaries.

The Economy.—The economy of Sikkim is based on its agriculture, and the chief crops are rice, maize (corn), millets, barley, oranges, apples, pineapples, cardamom, and potatoes. Woolen cloth is also produced and handloom cotton weaving is an important domestic industry. The main exports are cardamom, oranges, apples, and potatoes. Most trade is with India, which supplies Sikkim's essential imports, including textiles and foodstuffs. Sikkim has no railways or air communications but, with Indian help, motor roads of strategic importance are being built, and by the early 1960s about 300 mi. of such roads had been constructed. In the mid-1960s Sikkim was engaged in an intensive development program, financed entirely by India. Emphasis in the second Five-Year Plan was on the improvement of agricultural products and methods, communications, and on the training of Sikkimese youth. (Wr. L.)

SIKORSKI, WLADYSLAW (1881–1943), Polish military commander and prime minister of the Polish government-in-exile during World War II. He was born on May 20, 1881, at Tuszów Narodowy in Galicia. The son of a teacher, he graduated in engineering at Lwow (Lvov). A reserve officer of the Austrian Army, he was, with Jozef Pilsudski (*q.v.*), one of the founders, in 1908, of the Polish secret military organization, and from August 1914 to September 1916, during World War I, he headed the military department of the Supreme National Committee, organizing the Polish Legions to fight on the Austrian side against Russia (Pilsudski objected to his pro-Austrian policy as shortsighted). Having distinguished himself in the Russo-Polish War (*q.v.*) in command of an army operating in Polesie and then, from August 1920, of one fighting north of Warsaw, Sikorski was appointed chief of the Polish general staff on April 1, 1921.

After the assassination of Pres. G. Narutowicz, Sikorski became prime minister in December 1922 but resigned in May 1923. As minister of military affairs from February 1924 to May 1925, he contributed to the modernization of the armed forces. Commander of the Lwow army corps from December 1925, he remained neutral during Pilsudski's *coup d'état* of May 1926. Even so, he was dismissed from his post in March 1928. He then began to write on military and political matters and joined the anti-Pilsudski group headed by I. J. Paderewski, Wincenty Witos, and Wojciech Korfanty.

On the outbreak of World War II, Sikorski went to Paris to become prime minister of the Polish government-in-exile and commander in chief of the Polish forces. After the collapse of France in 1940 he moved his government to London. He won the esteem of Winston Churchill and on three visits to the U.S. (1941–42) discussed problems of grand strategy, as well as revision of Poland's western frontier, with Pres. Franklin D. Roosevelt.

Sikorski concluded an agreement on political and military cooperation with the U.S.S.R. (July 30, 1941) and visited Stalin in Moscow, where a joint declaration of mutual assistance was signed (Dec. 4, 1941). In April 1943, however, his government asked the International Red Cross to investigate the murder, at Katyn, of thousands of Polish officers who had been prisoners of war in Soviet hands. Stalin thereupon severed Soviet-Polish diplomatic relations. On July 4, 1943, on a return flight from the Middle East to London, Sikorski perished in an air crash at Gibraltar.

See Gen. M. Kukiel *et al.*, *General Sikorski* (1954). (K. Sm.)

SIKORSKY, IGOR IVAN (1889–), pioneer airplane designer and manufacturer. He was born in Kiev, Russia, May 25, 1889, and educated in Kiev, Petrograd and Paris. At an early age he turned his attention to aeronautics and in France and Germany studied the work of Blériot (*q.v.*) and Zeppelin. In 1909 he designed and built his first flying machine, a helicopter but it was not successful and he turned to conventional fixed-wing airplanes. By 1911 he had produced five successful machines and become an accomplished pilot.

During the period 1913–17 Sikorsky designed, built and flew planes that were remarkable for their size and flying range. They were powered by four engines and were the precursors of the modern airliners and large bombers.

In 1919 Sikorsky moved to the United States and became a citizen in 1928. He established an aircraft firm on Long Island that later became a division of United Aircraft corporation. His organization turned out a long series of land planes, seaplanes and amphibians that were used by the military services and commercial airlines.

In 1939, Sikorsky returned to his original interest in the helicopter, and produced the first successful direct-lift machine in the United States. He continued active development of this type until his retirement from United Aircraft corporation in May 1957. (S. P. J.)

SILAGE: *see* ENSILAGE.

SILAS, SAINT (fl. A.D. 50), early Christian prophet and missionary, was the companion of St. Paul (*q.v.*) on the second journey, when he took the place formerly held by Barnabas. The tour included southern Galatia, Troas, Philippi (where he was imprisoned), Thessalonike (Salonika), and Beroea, where Silas was left with Timothy, though he afterward rejoined Paul at Corinth.

He is in all probability the Silvanus (the abbreviation is similar to that of Prisca for Priscilla and Sopater for Sosipater) who is associated with Paul in the letters to the Thessalonians, mentioned again in II Cor. 1:19, and the bearer and amanuensis of I Pet. (5:12). It is possible, indeed, that he has an even closer connection with this letter (*see* PETER, EPISTLES OF SAINT: *I Peter: Authorship and Date*), and some scholars are inclined to give him a prominent place among the writers of the New Testament. He was of Jewish birth and probably also a Roman citizen. St. Silas' feast day is July 13 in the West, July 30 in the East.

SILCHESTER, a parish and village in Hampshire, England, 10 mi. SW of Reading. The parish contains the site of the Romano-British town of Calleva Atrebatum, excavated in 1864–78, 1890–1909, and 1938–39 (results published in *Archaeologia*). Soon after the Roman conquest Calleva became the cantonal capital of the Atrebates and the centre of a road system. The outer earthworks enclosed 230 ac., the inner (about A.D. 160–170) 100 ac. The street plan divided Calleva into 37 *insulae* and there were a forum, basilica, public baths, several temples, a Christian church, and an amphitheatre. (*See* BRITAIN: *Roman Britain*.) The main collection of antiquities from the site is in the Reading Museum; the Calleva Museum (opened 1951) illustrates the town's life. Pop. (1961) 511.

See G. C. Boon, *A New Guide to the Roman City Calleva Atrebatum at Silchester, Hampshire* (1952).

SILENUS: *see* SATYRS AND SILENI.

SILESIA (Polish SLASK, Czech SLEZSKO, German SCHLESIEN), an old Polish province which became a possession of the Bohemian crown in 1335, passed with that crown to the Austrian Habsburgs in 1526, was taken by Prussia in 1742, and returned to Poland in 1945. Bounded by the Sudeten Mountains to the southwest, by the Beskid Range to the south, and by the Cracow-Wielun plateau to the northeast, it covers the basin of the upper and middle Oder (Odra) River.

The Name.—The German historian Ignaz Imsieg, writing in 1830, derived the name Silesia from that of the Silingi, a Vandal tribe, but that tribe stayed in Silesia only for a relatively short period and migrated southward about the end of the 3rd century. Polish historians maintain that the name derived from the Sleza River (German Lohe), a left-bank, northward-flowing tributary of the Oder, to the east of the mountain of the same name. Frantisek Palacky, the Czech historian, believed that *Slezane* (the Czech name for the Silesians) was a Slavonic transcription of Silingi. Wladyslaw Semkowicz, a Polish historian, demonstrated in 1933 that the name *Silingi* itself described the people living along the Sleza. By the 9th century the population of Silesia was exclusively Slavonic: the Dziadoszanie and the Bobrzanie occupied the north of the country, the Slezanie the

THE REGION OF SILESIA

middle, and the Opolanie and the Golensicowie the south. Because of their central position, the Slezanie gave their name to the province, which the old Latin chronicles of the Poles called *Slansco* (1132) or *Zlesia* (1163).

The First Polish Period.—By the 10th century Silesia was a disputed territory between the Czech dynasty of the Premyslids and the Polish dynasty of the Piasts, but between 989 and 992 Mieszko I, prince of Poland, acquired Silesia from Boleslav II, prince of Bohemia. Boleslaw I the Brave, king of Poland, consolidated this possession by founding a bishopric in 1000, with its seat first at Smogorzow (German Schmograu), when it was later transferred to Wroclaw (Breslau). This diocese, covering the territory of historic Silesia, was subject to the archbishop of Gniezno, whose seat was at that time the capital of Poland.

When Boleslaw III the Wry-Mouthed, prince of Poland, died in 1138, he left a statute dividing his lands between his four sons. Wladyslaw, the eldest, received Silesia, with overlordship over all the other Polish territories; in 1146 he was evicted by his brothers, against whom he had allied himself with the German king Conrad III. In 1163, however, under pressure from Conrad's successor, the Holy Roman emperor Frederick I Barbarossa, Silesia was restored to Wladyslaw's two elder sons, Boleslaw I the Tall (d. 1201) and Mieszko the Knock-Kneed (d. 1211): Boleslaw became prince of Lower Silesia, with Wroclaw as his capital, Mieszko of Upper Silesia, with Opole (Oppeln). In 1203 a third principality, with Glogow (Glogau) as capital, was created for Konrad, Wladyslaw's third son.

The princes of Wroclaw constituted the senior branch of the Silesian Piasts. Henry I the Bearded, Boleslaw's son, who reigned from 1201 to 1238, tried to reunite the Polish kingdom. His son, Henry II the Pious, pursued the same policy, but was killed in the great Battle of Legnica (Liegnitz) on April 9, 1241, where at the head of an army of Polish and German knights he checked the Tatar invasion which had devastated the country. All the Silesian Piasts encouraged the immigration of German peasants, artisans, and merchants to promote economic growth; forests were cleared, swamps drained, new towns founded, and the mining and textile industries developed—at the cost, inevitably, of a progressive germanization of the country.

As the Silesian Piasts were prolific, the three existing principalities were subdivided again, and by the end of the 15th century there were no less than 16 Silesian principalities. They were (from

the northwest to the southeast): Glogow, Zagan (Sagan), Wolow (Wohlau), Legnica, Jawor (Jauer), Olesnica (Oels), Wroclaw, Swidnica (Schweidnitz), Brzeg (Brieg), Grodkow-Nysa (Grottkau-Neisse), Ziebice (Münsterberg), Opole, Raciborz (Ratibor), Krnov (Jägerndorf), Opava (Troppau), and Cieszyn (Teschen, or Tesin). All of these acknowledged a certain unity, which was expressed in periodical meetings of the ruling princes, under the presidency of the senior of Piast of the Silesian line.

The Bohemian Period.—The petty Silesian princes often sought the help of the powerful kings of Bohemia against their own brothers and cousins, thus enabling those monarchs to revive their old claims to overlordship. In 1335, at Visegrád, an arbitral award rendered by Charles I of Hungary (Charles Robert of Anjou-Naples) assigned all Silesia to the Bohemian crown in return for the renunciation by the Bohemian king of his further claims to the Polish crown; this settlement was accepted by the Polish king Casimir III the Great. The change was, however, only one of overlordship: the Piast princes remained hereditary rulers of their own principalities so long as their lines survived; and only on the extinction of any line could the king of Bohemia take possession of the principality and assign it to a new prince. Though Bohemia was part of the Holy Roman Empire, the Piasts of Silesia were allowed to retain their status as Polish princes.

Silesia belonged to the lands of the Bohemian crown, but not to Bohemia. On various occasions on which the will of its Estates had to be consulted (chiefly on questions of succession) Silesia took a line different from Bohemia, though in practice usually identical with that of Moravia. In the 15th century Silesia took the side of the emperor Sigismund against the Bohemian Hussites (*q.v.*) and was in consequence heavily ravaged in the Hussite Wars of 1425–35, the German element suffering severely. Feeling in the country itself was divided, and when George of Podebrady ascended the throne of Bohemia in 1457, most of the Silesian princes recognized his suzerainty. The towns, however, led by Wroclaw, resisted, and, because of this, the Hungarian king Matthias I (*q.v.*) Corvinus was able to rule Silesia (with Moravia) from 1469 to 1490. On his death, Silesia reverted to the Bohemian crown, from whose weak holder, Vladislav II, the Estates exacted concessions which made them virtually independent.

The Habsburg Period.—On Dec. 5, 1526, the Silesian Estates accepted without demur the succession of the Austrian archduke Ferdinand, of the Habsburg dynasty (*see* FERDINAND I, Holy Roman emperor) to the Bohemian crown, though the surviving Piast princes claimed that this could not affect their own rights, and one of them, Prince Ferdinand II of Legnica, concluded a *pactum mutuae successionis*, or reciprocal treaty of inheritance, of his own with the elector Joachim II of Brandenburg (1537). This had no immediate effect, and Silesia remained entirely under the Habsburgs, who reduced its internal liberties, while tending to emphasize its independence of Bohemia. When the archduke Rudolf (the future emperor Rudolf II) was elected king of Bohemia in 1575, the Silesian princes became princes of the Empire.

The Reformation turned Silesia almost entirely Protestant. Consequently, on the outbreak of the Thirty Years' War, the Silesians joined the Bohemians in their struggle against the Habsburgs. Though intervention by Lutheran Saxony, from 1621, obliged the Habsburgs to acknowledge some formal measure of religious tolerance in Silesia, so that the Counter-Reformation could not be fully enforced there, the country was repeatedly overrun by contending armies and pillaged by mercenary bands. Under the Peace of Westphalia (1648), thanks largely to pressure from Sweden, a few towns were allowed to have Protestant churches, besides the freedom of worship which the princes enjoyed; and relations with Protestant communities abroad were permitted. In 1707, during the great Northern War (*q.v.*), Charles XII of Sweden obtained the Convention of Altranstädt from the emperor Joseph I, whereby the latter undertook to restore 128 churches to the Protestants, with permission to build more. Silesia was again the most Protestant part of the Austrian Habsburgs' dominions. Meanwhile it had been making an economic recovery: the Austrian mercantilist reformers of the late 17th and early 18th centuries made the development of its mining and textile industries the cornerstone of their plans, and before long Silesia counted as the richest of all the Austrian provinces, while Wroclaw was now one of the largest and richest cities of the empire.

The Prussian Period.—It was chiefly its wealth that tempted Frederick II of Prussia to wrest Silesia from the Habsburg heiress Maria Theresa in the War of the Austrian Succession (*q.v.*), which he began in 1740. His excuse was the old treaty of 1537, although his own great-grandfather had in 1686 renounced his claims under that treaty in return for the cession of the district of Swiebodzin (Schwiebus). Under the Treaty of Berlin of July 28, 1742, Maria Theresa was obliged to cede to Frederick all of Lower Silesia and Upper Silesia except the districts of Krnov, Opava, and Cieszyn. The Austrian attempt to recover all Silesia in the Seven Years' War (*q.v.;* 1756–63) came to nothing. What was left of Austrian Silesia was united to Moravia till 1849, when it was made a separate crownland.

Frederick's action in seizing Silesia had not been at all unwelcome to the German and Protestant Silesians, and it brought them many benefits. Frederick devoted much attention to his new acquisition, which was at first placed under a special *Landesminister*. The old Estates were abolished, and a more efficient administration was introduced. Great attention was paid to economic development. In 1815 Prussian Silesia was enlarged by the incorporation of Saxon Lusatia. In 1818 the diocese of Wroclaw ceased to be subject to the Polish metropolitan of Gniezno and passed under direct administration of the Holy See.

With the increasing importance of coal, in which Upper Silesia proved very rich, economic development proceeded even more rapidly than before, until it became an industrial district second in Germany only to the Ruhr area. Lead and zinc, as well as coal and iron, were mined and utilized in factories on the spot.

Lower Silesia was by this time purely German. In Upper Silesia, except for its western portions, the population was mixed. Most of the towns were almost entirely German, but many of the agricultural districts were Polish, and a fair proportion of the miners and unskilled industrial workers were Poles.

The Settlement of 1919–21.—In 1919, after World War I, both Poles and Czechs laid claim to parts of Prussian Silesia, while conversely the Germans of Austrian Silesia asked to be incorporated in Germany. Further, while the Czechs claimed the whole of Austrian Silesia, partly on grounds of historic right, Poland claimed Upper Silesia and part of Cieszyn Silesia as Polish by majority. On July 28, 1920, the principal Allied powers laid down a frontier which divided the Cieszyn area and the town itself between Poland and Czechoslovakia. (*See* TESCHEN.)

There remained the largest question of all: that between Germany and Poland. When the draft of the Treaty of Versailles (*q.v.*) was handed to the German delegation on May 7, 1919, it comprised the transfer to Poland of the greater part of Upper Silesia according to the ethnic boundary between the two nationalities, easy to establish on the basis of the Prussian census of 1910. However, in response to Germany's vigorous protests, contained in the *Remarques de la délégation allemande sur les conditions de la paix* (May 29), this decision was modified under the pressure of David Lloyd George, the British prime minister. The final treaty provided that the population should declare by plebiscite, by communes, whether it wished to belong to Germany or Poland.

In the poll (March 20, 1921), 706,820 votes were cast for Germany (including 182,288 emigrant votes brought from Germany to the plebiscite area) and 479,414 for Poland. In all, 682 communes voted for Poland and 792 for Germany, but the Poles secured preponderance in the southeastern plebiscite area, which economically was the most important; and in May 1921, the Polish plebiscite commissioner, Wojciech Korfanty (*q.v.*), ordered an armed rising. The dramatic struggle for Upper Silesia ended seven months later when, on Oct. 20, 1921, the principal Allied powers endorsed the award of the Council of the League of Nations of Oct. 12, whereby three-quarters of the coal-producing area and nearly two-thirds of the steelworks went to Poland. Lower Silesia, meanwhile, was left to Germany. (*See* POLAND: *The*

Treaty of Versailles and Frontier Problems.)

The Settlement of 1945.—Germany overthrew the settlement of 1921 by attacking Poland on Sept. 1, 1939, thus starting World War II. Polish Upper Silesia was annexed to Germany, which on Dec. 12, 1940, divided its newly reunited Silesian province in two *Gaue:* Lower Silesia, with Breslau (Wroclaw) as its capital; and Upper Silesia, with Kattowitz (Katowice). Polish patriots, especially those who took part in the Upper Silesian rising of 1921, were arrested and shot without trial, and educated Poles were deported from Silesia to the German-administered *General-Gouvernement* of Poland. Silesia was subjected to a policy of forcible germanization and settled by Germans evacuated from the territories which, according to the Ribbentrop-Molotov agreement of Sept. 28, 1939, were temporarily described as the Soviet sphere of interest. (*See* POLAND: *Poland During World War II.*)

In 1942 the Polish government-in-exile in London, supported by the resistance leaders in Poland itself, claimed a radical revision of Poland's western frontier, arguing that this was necessary for political, economic, and moral reasons. Politically, it was important to ensure Poland's security by giving it the shortest possible frontier with Germany, namely the Oder-Lusatian Neisse line; economically, it was imperative to compensate Poland for the loss of eastern provinces (to the U.S.S.R.) so that it could transfer westward its refugees from the east as well as the surplus of its population in central provinces; and morally, the new territorial settlement should show to the German people that Nazi war crimes could not go unpunished. It was in this spirit that the representatives of the United Kingdom, the United States, and the U.S.S.R. decided at Potsdam, on Aug. 2, 1945, to assign nearly all German Silesia to Poland and to transfer its German population to the Allied-administered Germany.

Silesia as a German *Provinz* covered until 1939 an area of 36,696 sq.km. (14,168 sq.mi.) with a population of 4,815,800 (census of May 17, 1939), including more than 500,000 Poles. It had a density of population of 131 inhabitants per sq.km. (340 per sq.mi.).

The pre-1939 Polish province (*województwo*) of Silesia composed the part of Upper Silesia attributed to Poland in 1921 (3,205 sq.km.) and the Cieszyn area (1,011 sq.km.). The total area of Polish Silesia was 4,216 sq.km. (1,628 sq.mi.) with a population of 1,312,000 (estimate of Sept. 1, 1939).

After World War II the major part of German Silesia became Polish, with the exception of the districts west of the Lusatian Neisse (Hoyerswerda, Rothenburg, and the western half of Görlitz) attributed to the German Democratic Republic. Five of the northern districts of formerly German Silesia (Zielona Gora [Grünberg], Kozuchow [Freystadt], Glogow, Wschowa [Fraustadt], and Szprotawa [Sprottau]) became parts of the new Polish province of Zielona Gora. The remainder was united with Polish Silesia, to which had been added five districts of the former province of Kielce (Bedzin, Zawiercie, Myszkow, Czestochowa, and Klobuck). In 1950 Polish Silesia was divided into three provinces with capitals in Wroclaw, Opole, and Katowice. Their total area was 38,076 sq.km. (14,701 sq.mi.), with an almost entirely Polish population of 6,440,377 (1960). The density of population was 182 inhabitants per sq.km. (471 per sq.mi.).

SILHOUETTE. The word silhouette especially means a profile portrait cut out of black paper; but it is also used for any outline or sharp shadow of an object.

The term was taken from the name of Étienne de Silhouette, the parsimonious finance minister of France in the middle of the 18th century whose hobby was the cutting out of paper portraits (the phrase "*à la Silhouette*" originally meant "on the cheap"). Silhouette's hobby was also that of later famous persons, including Johann von Goethe. Collectors today look for both the painted and the cut silhouettes of the 18th and early 19th centuries, notably items by such artists as Francis Torond, A. Charles, John Miers, C. Rosenburg, Mrs. Brown, Auguste Edouart, T. Hamlet and Mrs. Beetham (nee Isabella Robinson).

The art of the paleolithic peoples, of several different eras, that made mural paintings and drawings in the limestone caves of France and Spain, is distinguished by a brilliantly realistic representation that appears to have been first achieved by drawing the outline of the object's shadow, which was generally filled in with a flat colour. Representation by profile-drawing persisted long after pictures and sculptures became conceptual rather than realistic (*e.g.*, the tomb paintings and relief sculpture of Egypt and the finely executed decorations on Greek and Etruscan pottery). The ancient Greeks knew how to draw the outline of a person's shadow cast by sunlight. Profile portraiture executed by using a candle or a lamp to throw the shadow on a wall or screen had become fairly common in Europe by the 17th century. Professional practitioners began to paint shadow portraits on any suitable material—plaster, wax, glass, vellum, paper—and to mount them, sometimes quite elaborately; and various mechanical devices were adopted to facilitate correct drawing. When paper became generally available the outline of the shadow was often cut out, and the cleverer practitioners learned to cut the portraits directly from life and to make more elaborately composed pictures. In the 18th century the painted "shade" and the paper-cut both became fashionable. After the coming of the daguerreotype and photography a few genuine artists, such as Phil May, sometimes made use of the painted shadow style in caricature; otherwise it can be said to have died out, except that the cut silhouette persisted.

By the second half of the 20th century there were still a few good silhouette-cutters (for example the Englishmen Hubert Leslie and H. L. Oakley), but the underlying principles of the art lived most vigorously in the cartoon film, in the work, for instance, of Walt Disney and of Lotte Reiniger. (R. L. M.)

SILICA is a compound of the two most abundant elements of the earth's crust, oxygen and silicon (*q.v.*). It is the main constituent of more than 95% of the earth's rocks. Its resistance to change gives it special significance in geology and important applications in many chemical processes requiring a refractory (heat-resistant) substance. It occurs in a great variety of forms; the principal industrial sources are sand (quartzose types), quartzite and sandstone (*qq.v.*).

Silica is silicon dioxide, SiO_2. By weight, it contains 46.75% silicon and 53.25% oxygen. It constitutes 59% of the mass of the solid crust of the earth, occurring both as free silica and in combination in the silicate minerals (*see* SILICON: *The Silicates*). The free silica found in rocks is almost universally crystalline quartz. Sea sand is quartz in the almost pure state.

Uses.—Buildings and roads consume the largest tonnage of silica, for sand is the ever-present constituent of portland cement concrete and lime mortar in construction work, and sandstone is one of the most permanent of building stones. The hardness of quartz becomes useful in the application of sand to the cutting, grinding and polishing of glass and stone, and in the consumption of a large tonnage of engine sand to prevent the slipping of driving wheels of a locomotive on a steel rail. The high melting point and low expansion coefficient of cristobalite make silica brick, usually manufactured from quartzite, one of the most useful of refractories, particularly in the steel industry. Another refractory use, consuming a large tonnage of sand, is in foundry molds. Low thermal conductivity adds to high melting point in making diatomaceous silica a popular refractory insulator for furnaces. Unusual insolubility in water and acids, together with negligible thermal expansion, gives vitreous silica a preferred place in chemical apparatus, both in the laboratory and in the plant.

As a chemical raw material, silica sand and rock enter into the manufacture of various products in which the silica, as such, largely disappears, to reappear in other combinations; these include glass, soluble silicates (water glass), ceramic products of various kinds, silicon carbide, ferrosilicon and silicones.

Pure silica is a chemical product as well as a raw material.

When fused with an alkali, dissolved, precipitated, washed and partially dried, it is obtained in an amorphous, very finely divided form which has unusual absorptive properties for water vapour, gases and the minute impurities in certain liquids.

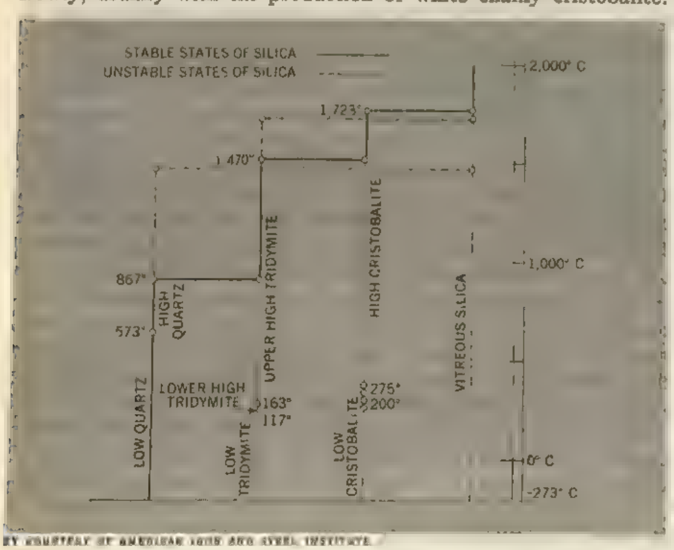
Principal Crystalline Forms.—Of the many forms of silica, the three principal crystalline forms are: quartz, tridymite and cristobalite. Quartz is the form that is stable, under atmospheric pressure, at all temperatures up to 867° C. Tridymite is the stable form from 867° C. to 1,470° C. Cristobalite is stable from 1,470° C. to its melting point at 1,723° C. (International Temperature Scale of 1948). The transformation of silica from one of these forms to another is sluggish, hence the two high-temperature forms can easily be preserved indefinitely at ordinary temperatures, while, conversely, quartz can be heated above 867° C. for hours or even for days and still remain either unchanged or only incompletely transformed into tridymite or cristobalite.

Three new crystalline forms of silica have been discovered since 1953: (1) coesite, which is stable only under high pressure and is the densest form of silica; (2) keatite, which is formed hydrothermally under high pressure and is possibly related to cristobalite in structure; and (3) a fibrous form discovered by A. and A. Weiss and sometimes designated silica W, which is produced by the oxidation of silicon monoxide, SiO.

Each of the three principal forms exists in more than one polymorphous modification, depending upon the temperature. In contrast with the sluggish inversions mentioned above, these high- and low-temperature modifications are produced almost instantaneously when the inversion point is attained; only under very unusual circumstances is it possible to hold the high-temperature modification at a lower temperature than its normal range. These quick-changing modifications were formerly designated by Greek letters, such as alpha and beta, but because of confusion arising from differences in the convention as to which modification should be called alpha, it is clearer to refer to them by the words high and low, or upper and lower. They are so designated in the figure.

The high-low inversion of quartz is at 573° C. Tridymite has two such inversions, at 117° and 163° C. Cristobalite is peculiar among polymorphous substances in that its high-low inversion point changes through a range of temperature (200°–275° C.) according to the previous history of the cristobalite.

Imitating the sluggishness of the inversion between the principal crystalline forms, molten liquid silica when cooled below 1,723° C., crystallizes sluggishly and can therefore be easily cooled to an amorphous glass, called vitreous silica, fused quartz, or silica glass. (This property persists in the silicate glasses.) Vitreous silica is often incorrectly called quartz, but quartz is a crystalline substance of completely different properties. Upon long-continued heating at temperatures above 1,100° C. vitreous silica devitrifies slowly, usually with the production of white chalky cristobalite.



BY COURTESY OF AMERICAN IRON AND STEEL INSTITUTE

STABLE AND UNSTABLE STATES OF SILICA

As the figure indicates, both quartz and tridymite can be melted at temperatures lower than the stable melting point of 1,723° C., but unless further heated to a temperature above 1,723° the fused silica so produced would gradually change over into cristobalite.

Silica is measurably volatile at temperatures above 1,600° C., but its vapour pressure is extremely small. The fluffy porous white deposits of silica often seen around electric furnaces usually are not due to direct distillation, but to reduction of SiO_2 by carbon monoxide and hydrogen to form volatile Si or SiO and gaseous SiH_4, which are subsequently reoxidized.

The Silica Minerals.—All of the three polymorphous crystalline forms mentioned above occur as natural minerals, and even the vitreous (glassy) form, though rare, has been found as a natural product. In combination with water in varying amounts up to about 12%, furthermore, silica occurs as the amorphous mineral opal. Finally, mixtures of hydrated and microcrystalline silica, over the whole range of possible proportions, occur in nature and can be grouped together as chalcedonic silica.

Cristobalite, the crystalline form stable at the highest temperature, always occurs as the low-temperature modification (*see* figure) but its external crystal form shows it to have grown at a temperature above the inversion range of 200°–275° C. Tridymite, likewise, occurs as the low modification, but its habit of growth in twinned hexagonal plates shows that it formed above 163° C. Both of these minerals are instances of Ostwald's rule, which states that a form of low or intermediate stability has a better chance of growing than the form that is most stable under the prevailing conditions.

Natural vitreous silica is called lechatelierite. It is the material constituting the peculiar tubes often found in sand, known as fulgurites, and produced by the intense local heating due to a stroke of lightning. It occurs in the meteor crater of Arizona, again a product of sudden and intense heating. An unexplained occurrence of lechatelierite is the scattered fragments found over a considerable area in the Libyan desert.

The foregoing (cristobalite, tridymite, lechatelierite) are relatively rare minerals. In extreme contrast is quartz, the world's second most abundant mineral (feldspar being first). It has received many names, differentiated according to external form, colour and visual effects caused by inclusions. Clear, colourless, well-crystallized quartz is often called rock crystal, and it received local names like "Herkimer diamond." It exhibits several types of twinning (*see* QUARTZ) and is frequently found as a pseudomorph of other minerals. The clear varieties which are coloured uniformly by various impurities include amethyst (purple, violet); sapphire quartz (indigo, blue); blue quartz; citrine and false topaz (yellow); rose quartz (pink and rose-red); smoky quartz and cairngorm stone (yellow to brown); and morion (deep brown). Inclusions of gas bubbles give rise to milky quartz; of red hematite, to ferruginous quartz; of needles of rutile (TiO_2) or tourmaline, to sagenitic quartz; of fine fibres and streaks of various composition, to cat's-eye and tigereye.

Like euhedral and massive quartz, the chalcedonic silica minerals have received a variety of names based upon visual characteristics. Because of their microfibrous structure, they all show a waxy lustre on a natural or a fractured surface. If visually homogeneous, nearly colourless and translucent, the mineral is chalcedony. Translucent green makes it chrysoprase, or prase if leek-green. Bright green due to chlorite inclusions produces plasma.

Other translucent varieties are bloodstone and heliotrope (green with red or yellow spots), carnelian (red or yellowish-red), and sard (brown). When banded instead of visually homogeneous, the mineral is agate, of which onyx and sardonyx are subvarieties characterized by banding in planes rather than curving surfaces. The less-prized, because opaque, varieties of chalcedonic silica are jasper, which is usually red, yellow or brown, and may even be green and bluish gray; flint, which is gray to black with conchoidal fracture; and chert, likewise gray to black with splintery conchoidal fracture.

Hydrated, apparently amorphous silica is usually given the name opal, of which the varieties used for gem cutting are characterized

by iridescent colours. Hyalite is the colourless and transparent form of opal. Although opal shows no evidence of crystallinity under the microscope, the X-ray reveals it to have, at least in part, the internal structure of cristobalite. An interesting structural form of opaline silica is the material called diatomite, which consists of microscopic skeletons of fresh-water diatoms. Sponge spicules are also essentially opaline silica. (*See* DIATOMACEOUS EARTH.)

Physical Properties.—The density of the principal forms at 0° C. is: quartz 2.651, tridymite 2.26, cristobalite 2.32, vitreous silica 2.203.

The thermal expansion of the crystalline forms is greatly influenced by the high-low inversions, in that the expansion coefficient becomes steadily greater as a polymorphous inversion point, like that of quartz at 573° C., is approached. At the inversion point there is a sudden increase of volume in going over to the high-temperature modification, after which there is relatively little change with further rise in temperature. High quartz actually contracts a little with rising temperature. Vitreous silica has an expansion coefficient which is near zero at all temperatures. This property gives it a special industrial value, for it can be suddenly heated, or chilled from a bright red heat (as by plunging in water) without breaking.

The specific heat of the forms at 0° C. is: quartz 0.1664, cristobalite 0.170, vitreous 0.1657. The curves of specific heat against temperature have the usual form, rising from zero at the absolute zero of temperature, interrupted by a discontinuity at the high-low inversions, and approaching a value of about 0.28 at the melting point.

The thermal conductivity of vitreous silica is uniformly low at all temperatures, about 0.003 cal. per square centimetre per second, per degree centigrade per centimetre at 0° C. Quartz, in contrast, while in a class with vitreous silica at ordinary temperature, rapidly increases in conductivity as the temperature falls and at the temperature of liquid hydrogen conducts as well as some metals.

The forms of silica are both hard and strong. Quartz is standard substance no. 7 in the Mohs' scale of hardness. A tensile strength as high as 160,000 lb. per square inch has been observed in drawn fibres of vitreous silica, and fibres that will carry 100,000 lb. per square inch are easily made. The vitreous form is singularly free from elastic anomalies and is therefore prized for various physical instruments.

The forms of silica are diamagnetic, with a mass susceptibility of about -0.5 per gram. They are poor conductors of electricity; the resistivity of vitreous silica at 20° C. is about 10^{19} ohms per square centimetre per centimetre, which makes it popular as an electrical insulator. It is especially valuable in such service because, unlike common glasses and many other substances, it does not condense a conducting layer of moisture upon its surface. (For other electrical properties, *see* QUARTZ.)

Both quartz and vitreous silica are colourless and transparent in visible light, and are unusually transparent to ultraviolet light. This property makes the vitreous form valuable in windows for transmission of whole sunlight, and in lamps for transmitting ultraviolet from the mercury arc. At wave lengths longer than visible light, on the other hand, though more transparent than other glasses to most of the infrared spectrum, silica reflects like a metal in the vicinity of wave length 9 μ, and has considerable reflecting power also near 13 and 23 μ.

The useful optical properties peculiar to crystalline quartz, particularly rotatory power, are discussed in the article QUARTZ.

Chemical Behaviour.—In the laboratory, crystalline and vitreous silica are virtually insoluble in pure water and dissolve very slightly in water solutions of the common mineral acids. Silica is attacked (etched), however, by dilute alkaline solutions and by concentrated phosphoric acid, and is rapidly dissolved by a solution of hydrofluoric acid (HF). The only halogen that attacks it is fluorine.

A homogeneous liquid containing only water and a few per cent of silica is easily obtained by acidifying the water solution of an alkaline silicate and dialyzing out the electrolytes. This liquid proves to be a hydrosol, containing silica units of large molecular weight, and not a true solution. Much experimental work was done on these sols in the hope of proving them to be silicic acids analogous to sulfuric and phosphoric acids, but without success. The sol can be concentrated to a stage where it becomes a rigid and elastic gel, corresponding to the natural mineral opal. The percentage of water in such gels is controlled by the temperature and by the water vapour pressure in contact with the gel, as well as by its previous chemical and physical history.

As the temperature rises, silica becomes measurably soluble in water, and continues to increase in solubility, if the pressure is increased, even above the critical temperature of water, 374° C., where surface tension disappears and gas and liquid become continuous in properties. At the critical end point of the solution, which is less than one degree higher than the critical temperature of water, and at the pressure corresponding to coexistence of quartz, liquid and vapour, quartz is soluble to the extent of 0.023% by weight. Its maximum solubility under these equilibrium conditions is 0.075%, at 332° C. Above the critical point, at higher pressures, a concentration of more than 0.3% has been attained. Vitreous silica attains an apparent equilibrium with water at about twice the concentration of quartz.

Silica in all forms reacts at temperatures above 1,000° C. with all metallic oxides, also with many salts when in the presence of air and moisture, to form crystalline or liquid silicates.

SILICON is the second most abundant of the elements in the earth's crust, surpassed in quantity only by oxygen. It is found in measurable amount in practically every rock, in all natural waters, in the atmosphere (as siliceous dust), in many plants and in the skeletons, tissues and body fluids of some animals. Its presence in the sun and other stars is indicated by the spectroscope. It is never found in the free state, however, but always in combination—either with oxygen as silica (SiO_2), or with oxygen and aluminum, magnesium, calcium, sodium, potassium, iron and other elements in the numerous silicate materials which comprise rocks, soils and clays.

Prior to 1787 chemists had not differentiated silicon from its compound, silica, which they considered an element. In that year A. Lavoisier offered the speculation that silica was an oxide of an undiscovered element. In 1817 J. J. Berzelius found that the substance, free from oxygen, was present in cast iron; and six years later he established its existence as an element, although he was able to prepare it only in somewhat impure form. It was first obtained in reproducible crystalline form in 1854, when H. Sainte-Claire Deville crystallized it out of the alloy produced by electrolyzing a melt of mixed chlorides. The name silicon was derived from *silic-*, basal syllables of *silex*, Latin for "flint."

Silicon is chemical element no. 14 in the periodic system; symbol, Si. It is nonmetallic in character and has a chemical atomic weight of 28.086. Its isotopic composition, which has been found constant both in the earth's crust and in meteorites, is: Si^{28}, 92.28%; Si^{29}, 4.67%; Si^{30}, 3.05%. External electron arrangement: $1s^2\ 2s^2,\ 2p^6\ 3s^2,\ 3p^2$.

Forms.—Pure silicon crystallizes with isometric symmetry, and has the same structure as diamond. The distance between adjacent atoms is 2.35 Å.

Amorphous silicon has been frequently described, especially by the earlier workers. Some of it was undoubtedly impure as a result of the method of preparation, and was mixed with silicides and silica. Even when fairly pure, the supposed amorphous element has been found to give the same X-ray pattern as the recognizably crystalline form.

Preparation and Physical Properties.—Silicon is best prepared by reaction of metals such as magnesium, aluminum and potassium with the halogen compounds of silicon. It can be purified by recrystallization from metallic solution, as in aluminum, the excess of solvent metal being removed with acid. Because of the difficulty of preparing the pure element, the recorded physical properties are not as reliable as those of more easily purified substances.

The physical properties of silicon are as follows:

Density (grams per cubic centimetre)	2.42
Coefficient of thermal expansion at 0° C.	7×10^{-6}
Melting point	1,420° C.
Boiling point	about 2,600° C.
Specific heat at 0° C., calories	0.174
Refractive index, $\lambda = 589$ mμ	4.24

Chemical Behaviour and Uses.—Silicon is attacked by oxygen and water vapour at a red heat and higher, but the coating of SiO_2 formed by the reaction protects the element. It is vigorously attacked by gaseous fluorine, chlorine and hydrofluoric acid. It is not acted upon by sulfuric acid, hydrochloric acid, nitric acid or aqueous ammonia at ordinary temperature. Many oxides are reduced by silicon at high temperatures with the formation of metal or silicide, and silica.

Silicon is used in industry principally as the alloy of iron and silicon called ferrosilicon. This may contain from 14% to 94% Si. It is used for deoxidizing common steels and for making special silicon steels.

Compounds.—Silicon stands next to carbon in the fourth group of the periodic system. By simple analogy, this fact leads to the expectation that silicon can form chain and ring compounds with hydrogen and the halides, as well as a complex system of hydrogen-oxygen compounds. This expectation is to some extent realized in the simpler chain formulas of silicon compounds, and even the names, suitably modified, of the carbon-hydrogen-oxygen compounds have been carried over into the silicon series. New compounds are constantly being added to the silicon series.

Silicon has four electrons in the outer or valence shell. These are capable of pairing with the valence electrons of other elements to give four covalent bonds. Silicon is therefore commonly classed as tetravalent. The electrons can also be transferred to the outer shell of a strongly electronegative element such as fluorine to form bonds of ionic type. The covalent bonds of silicon to oxygen are estimated to be about half ionic in character. In the compounds of carbon, on the other hand, ionic bonds are rare. Further, carbon never produces more than four covalent bonds, and in some compounds the number descends to three and two.

Another important factor in the formation of compounds besides the electron arrangement is the size of the atom, controlling the space available for close approach of other atoms. Silicon has a larger atom than carbon. The co-ordination number of the silicon atom in its compounds is in nearly all cases four. With some atoms, however, such as fluorine and (occasionally) oxygen, it can be six. It is never less than four in any known compound.

These differences in external atomic structure find expression in the following striking differences between the carbon and silicon compounds of similar formula: (1) The carbon compounds form self-contained independent molecules which maintain their separate existence even though vaporized, liquefied, dissolved and modified by substitution of atom for atom; the silicon compounds polymerize and pass over into solid crystalline or amorphous aggregates, or structures extending infinitely in one, two or three dimensions. (2) In a world where water is always present as vapour or liquid, the carbon-based molecules survive untouched, the silicon-based molecules hydrolyze and end as hydrated silica or as water-bearing micas and clay minerals. (3) The carbon series build up their complexities by conjunction of carbon atom to carbon atom, while the silicon series build up their complexities mainly through the intermediary of oxygen atoms. It is easy to see that in a newly created world with prevailing temperatures of −50° to +100° C., carbon had within itself the possibility of an evolving life, while silicon was the possible parent mainly of cold rocks.

Hydrides.—Like carbon, silicon forms with hydrogen a series of compounds containing a progressively smaller proportion of hydrogen. The first member is silane, SiH_4, and the series has been prepared as far as Si_6H_{14}. All can be made by action of an acid on a silicide. All are gases at atmospheric temperatures. There are no unsaturated hydrides corresponding to the ethylene, acetylene and benzene types of hydrocarbons.

Oxides.—There is evidence for the existence of a monoxide, SiO, but little information is available on its properties.

The dioxide, SiO_2, usually called silica, is one of the most extensively investigated and best-known of chemical substances. (*See* SILICA.)

Compounds With Hydrogen and Oxygen.—A number of such compounds, called by the generic name siloxanes, had been prepared and studied by mid-20th century, but they lack the stability and the variety of behaviour characteristic of the analogous organic acids, esters, etc.

Halogen Compounds.—Silicon tetrafluoride, SiF_4, is a gas formed by reaction of hydrofluoric acid, HF, on silica. It combines with excess HF to form hydrogen silicofluoride, also called hydrofluosilicic acid or fluosilicic acid, H_2SiF_6, which is stable in water solution, giving the ion SiF_6^{--}. K_2SiF_6 is one of the few potassium salts that is difficultly soluble in water, making this acid useful in chemical analysis.

Silicon tetrachloride, $SiCl_4$, is a colourless liquid of boiling point 57° C. It reacts with water, either liquid or vapour, to form HCl and hydrated SiO_2. This reaction has been utilized, by including ammonia with the vapour, to produce a military protective dense white smoke consisting of particles of SiO_2 and NH_4Cl. As might be expected from the analogy with carbon, there are chlorides Si_2Cl_6, Si_3Cl_8 and others. Silicon tetrabromide is a colourless liquid boiling at 153° C. The tetraiodide is crystalline, melting at 121° C. and boiling at 290° C.

Numerous halogen derivatives of the silicon hydrides are possible, and many have been prepared and described. An example is silico-chloroform, $SiHCl_3$.

Carbide.—Silicon carbide, SiC, forms at electric furnace temperatures from reaction of carbon with silica. It exists in at least eight crystalline forms. It has become an important industrial abrasive and refractory, under trade names such as Carborundum and Crystolon. (*See* SILICON CARBIDE.)

Organosilicon Compounds.—The introduction of silicon into carbon chains and rings—or, looked at from the other direction the introduction of organic radicals into the simpler silicon compounds—opens an immense variety of possible structures, some hundreds of which have been prepared and described. None of these compounds has been identified as a natural product, though some may be taking part in the growth of silicon-bearing plant and animal tissues. Among the new compounds are the industrially important silicones (*q.v.*) which derive by polymerization from the general formula R_2SiO, in which R is an organic radical such as CH_3, C_6H_5 and the like. Another group of carbon-bearing compounds comprises the silicates, such as the industrially useful tetraethyl orthosilicate, $(C_2H_5)_4SiO_4$. The term organosilicon compound is restricted to those that contain at least one silicon-carbon bond.

Sulfide.—Silicon forms a colourless crystalline sulfide, SiS_2; its structure is that of an infinitely long chain of tetrahedra, SiS_4, which share opposite edges, the parallel chains themselves being held together by weak residual forces. It therefore differs from silicates of the chain type in that SiO_4 groups share corners but not edges (*see* below).

THE SILICATES

More than 95% of the earth's rocks contain silica as their principal component. Any such rock can be seen, either by direct inspection or by examination under the microscope, to be an aggregate of minerals, each homogeneous, usually crystalline, and usually transparent. In many rocks, one of these minerals is pure silica in the form of quartz. Most of the other rock minerals contain silica in combination; they are the silicate minerals.

Many of these minerals have been artificially duplicated, usually

by high-temperature processes. New crystalline silicates, never found in nature, have also been produced by these same processes. Most of the silicates, both natural and artificial, are insoluble in water. A striking exception is the group of silicates of the alkali metals (lithium, sodium, potassium), which are obtainable as homogeneous water solutions containing silica in a wide range of proportions. These solutions can be concentrated to form glasses that still contain as much as 25% water. One such series, the sodium silicates, forms an important article of commerce, long known by the commercial name of water glass, now more commonly called silicate of soda. By fusion with two or more oxides, commonly sodium oxide (Na_2O) and lime (CaO), both introduced as carbonate, silica forms the silicate glasses.

This extremely varied lot of substances, the silicate minerals, the synthetic silica compounds and the silicate glasses, are grouped by the chemist under the name silicates. As the name itself implies, the silicates were regarded throughout the 19th century and the first quarter of the 20th century as salts of certain silicic acids, in the same sense that sodium sulfate is a salt of sulfuric acid. The analogy was temporarily useful, even though it proved to be very difficult to produce a silicic acid resembling in any way the chemist's better-known acids. Pure silica proved to be extremely insoluble in pure water, and the homogeneous phases containing only silica and water, which are obtainable by various methods, were found to contain mostly colloidal or dispersed silica, with very little truly dissolved silica. The methods of organic chemistry failed completely to throw any light on the constitution of the silicates, and the field remained one for unrestrained speculation, uncheckable hypothesis and unproductive analogy.

The advent of the X-ray methods of studying the structure of crystalline and amorphous solids made possible a resumption of progress in the chemistry of the silicates. Systematic knowledge of silicate structure and constitution at mid-20th century was based largely on X-ray work particularly on the crystalline substances, the glasses and the clays, combined with the atomic-volume principle elucidated by V. M. Goldschmidt and others. It developed that the guiding unit is a group having the formula SiO_4. In all the silicates, as well as in pure silica, there are groups of four oxygen atoms arranged in space at the corners of a tetrahedron. There is usually a silicon atom at the centre of the tetrahedron, but it can be replaced here and there by aluminum (in most cases not to exceed one out of four silicon atoms), and rarely by beryllium. At the same time, an occasional tetrahedral corner will be found occupied not by an oxygen atom but by a fluorine atom or an OH pair (hydroxyl). The systematization of all the silicates is based upon the various ways in which it is possible to interconnect the silicon-oxygen tetrahedra. The chemically basic or electropositive elements, such as Li, Na, K, Mg, Ca, Sr, Ba, Al (in part), Mn, Fe, fit into the openings between the tetrahedra in accordance with their atomic volume. The oxygen atom itself is larger than most of the silicate-forming atoms, which leads to the geometric possibility of fillable openings.

Silicate Structures.—Mineralogists and chemists are not in complete agreement as to the classification of the structures, but the main groupings are briefly characterized below, and some of the better-known examples are listed in parentheses. Some of the old names were still retained for lack of a more logical terminology.

Three-Dimensional Networks, or Silica Type.—All the tetrahedra share corners with other tetrahedra. The formulas contain the group SiO_2 or multiples thereof. The type includes silica itself; the feldspar group (orthoclase, plagioclase); the nephelite group; the cancrinite and sodalite groups in which certain electronegative units such as Cl, CO_3 and SO_4 are added to the structure; and the large zeolite family, with added molecules of H_2O as the principal structural characteristic.

Sheet Structures (Sometimes Called the Disilicate Type).—The tetrahedra are arranged in a plane, each being joined to other tetrahedra by three atoms in the plane. The type includes the aluminum disilicates (kaolin and other clay minerals); the nonaluminum member, talc; the analogous aluminum member, pyrophyllite; the chlorite family; and the micas (muscovite and biotite series).

Chain and Ring Structures, or Metasilicate Type.—These may be either chains or rings of tetrahedra, reminiscent in a way of the chain and ring structures of the chemistry of carbon. The chain structures, which are potentially infinite in length, include: single chain structures, containing SiO_3 or multiple thereof in the formula (pyroxene group, pyroxenoid family); double chains containing Si_4O_{11} in the formula (amphibole group); and other more complex chains. Ring structures include beryl and probably the tourmaline series.

Double Tetrahedral Structures, or Pyrosilicate Type.—Two tetrahedra share a single oxygen atom, giving formulas containing Si_2O_7. These silicates include the melilite group and the hemimorphite family.

Independent Tetrahedral Structures, or Orthosilicate Type.—There is no sharing of corners between tetrahedra, hence formulas contain the group SiO_4. The old formal derivation was from an imaginary silicic acid of the formula $Si(OH)_4$. These silicates include a varied assortment, such as the chrysolite group (olivine, forsterite, fayalite), garnet group and epidote group. Allied to these orthosilicates are some subsilicate minerals, in which not all the oxygen is in the independent tetrahedra (sillimanite, mullite).

Phase Equilibrium in Silicate Systems.—There is another approach to understanding the chemistry of the silicates which almost completely ignores the existence of atoms and proceeds on the thermodynamic basis of the Gibbs phase rule, determining experimentally the limits of stability of all the crystalline and liquid phases that can be produced synthetically. The work of the Geophysical laboratory of the Carnegie Institution of Washington, D.C., founded by A. L. Day in 1906, is the most extensive in this field. The method has the great advantage of proceeding from simple to complex systems and of covering the ground thoroughly as it goes, at least with respect to equilibriums readily attainable at high temperatures. It has the disadvantage of being faced with what might appear a numerically hopeless task. Hundreds and thousands of tests, short though they may be, are necessary for the complete survey of a system of three oxide components, and several such systems had been patiently completed by the 1950s, but no four-oxide system had been finished. Yet most silicate minerals contain at least five components and a great many contain ten. The total number of systems (unary, binary, ternary, etc.) that can be assembled from ten oxides is 1,023. Additional complications are: (1) the necessity, in systems containing the oxides of iron and manganese, of taking the metal and gaseous oxygen as the components, adding gaseous pressure as another variable; (2) the experimentally difficult problem of sealed high-pressure apparatus when water is one of the components. Nevertheless, the elucidation of the simpler systems had brought rich returns in such matters as the formulation of fundamental principles on the genesis of rocks, and the solving of industrial problems in ceramics.

Ten or more binary silicate systems are represented by reasonably satisfactory phase-equilibrium diagrams, together with six ternary systems (SiO_2 with the pairs Al_2O_3–CaO, Al_2O_3–MgO, CaO–MgO, CaO–K_2O, CaO–Na_2O, K_2O–Na_2O). Systems containing dissociable oxides are still fragmentary. Silicates of sodium and potassium with H_2O as a third component are fairly complete. Details will be found in articles on the individual metallic elements.

The Problem of Valence and Neutrality.—Implicit in both the atomic-structural approach and the phase-equilibrium approach to the study of the silicates is the chemist's basic assumption of the validity of Dalton's law of definite and multiple proportions. It is assumed, for instance, that the phases and the structures in a series of sodium aluminosilicates containing water can be correctly described in terms of the formulas SiO_2, Al_2O_3, Na_2O, and H_2O. But 20th-century chemistry, studying the metallic alloys and various inorganic systems containing solid solutions (*i.e.*, crystalline solutions), found that Dalton's rules are often only an approximation or a working limit, not an exact statement. In the system iron-oxygen, for example, there occurs one crystalline phase (wüstite) with a temperature range of stability from 560° to 1,424° C. and a range of composition from 23.10% to 25.60% oxygen, no point of which can be represented by a simple

integral relation between the atoms; the composition FeO (22.27% oxygen) lies entirely outside the field and is nonexistent as a phase. The wüstite phase is a crystalline solution of oxygen in iron or iron in oxygen, whose composition depends upon the pressure and temperature. This relation will certainly carry over into the iron-bearing silicates.

Furthermore, it became apparent from study of the adsorptive and base-exchanging power of many substances that not only can there be ionization in liquid solutions but also in crystalline substances as well, with the possible production of structures into which ions and polar molecules can be introduced as a part of the systematic structure, to be released again under the proper chemical environment. The silicates with sheet structure include many such substances. (*See* ADSORPTION; VALENCE.)

Silicates in Industry.—The silicates are the foundation material for the widely various ceramic industries. In the United States the word ceramic is held to embrace not only industries based upon clay, which is the traditional usage, but any industry utilizing earthy raw materials (sand, clay, feldspar, magnesite) to manufacture a product with the help of a kiln or a furnace. The ceramic industries in the United States therefore include glass, vitreous enamels, portland cement and certain electric-furnace products (abrasives); as well as structural clay products (building brick, paving brick, tile), refractories, earthenware (pottery, sewer pipe) and whiteware (china, decorative porcelain, electrical porcelain). Soluble silicates have been mentioned above.

Another class of industrial silicates, the silicate slags, is closely allied to the metallurgical industries. In the production and refining of some metals, an active reagent is the nonmetallic liquid floating on the surface of the metal, collecting and removing the gangue of the ore and also reacting with constituents in the metal. The metallurgical slag produced in greatest tonnage is blast-furnace slag from the manufacture of crude iron. It consists essentially of silica, alumina and lime, with subordinate magnesia. Some of it is utilized as raw material for portland cement. Slag from the open-hearth furnace for making steel contains principally silica, lime and oxides of iron and manganese; in some localities it is high enough in phosphorus pentoxide to be utilized as fertilizer. Slags from the acid and basic Bessemer processes and from the smelting and refining of copper, lead and tin are siliceous in varying degree.

(R. B. SN.)

SILICON CARBIDE (CARBORUNDUM). Silicon carbide is a crystalline compound of metallic silicon and nonmetallic carbon which is of great technical and industrial importance. It was discovered accidentally by Edward G. Acheson in 1891 while he was experimenting with the use of electrical energy for the production of artificial diamonds. Acheson was heating a mixture of clay and coke in an iron bowl with an ordinary arc light carbon in an attempt to convert the carbon to diamond, and found some bright hexagonal crystals attached to the carbon electrode. He thought that he had prepared a new compound of the carbon and the alumina (aluminum oxide) of the clay. Because the natural form of fused alumina has the mineral name of corundum (*q.v.*), he called the new compound carborundum. This name was originally protected as a trade name but in many places became synonymous with silicon carbide. In 1893 Acheson was granted a U.S. patent covering his invention. About the same time Henri Moissan produced a similar compound from a mixture of quartz and carbon. However, in a publication of 1903 Moissan ascribed the original discovery to Acheson.

The significance of the discovery was immediately realized by Acheson, for he found that the crystals approximated the hardness of the diamond. His early product was offered for the polishing of gems, and sold at a price comparable with natural diamond dust. The new compound was found to be attainable with cheap raw materials and with good yields so that it soon became of industrial importance as a manufactured abrasive of wide application.

Properties.—Silicon carbide, which has the chemical formula SiC, crystallizes in the hexagonal system. Five crystalline-type habits in the hexagonal system were isolated and described in the technical literature. The commercial product has crystals up to ½ in. (13 mm.) average dimensions in the hexagonal plane and thicknesses of up to ¼ in. (6 mm.) in the other dimension. The crystals are usually found closely interlocked into a massive porous structure, but occasionally fully developed crystals are formed in voids of the furnace ingots. These are the spectacular large, shiny crystals which are often exhibited as typical silicon carbide. Pure silicon carbide is clear with a slight green tinge. The index of refraction is very high, 2.648 for the ordinary ray and 2.691 for the extraordinary ray. A slight amount of impurity will change the colour from light green to blue, gray and black. Typical impurities in the crystal are aluminum, magnesium, calcium, graphite and free silicon, all of which change the colour to black when present in amounts up to 0.5%. The crystal begins to oxidize when heated in air at around 1,000° C., forming a film of silica over the surface. This film produces iridescent and attractive colours when the proper film thickness is developed.

Some natural silicon carbide was found in the Canyon Diablo meteorite and bears the mineralogical name Moissanite after Henri Moissan.

A low-temperature form of silicon carbide (β-SiC) was discovered and isolated in 1926 by H. Ott. It has the same chemical composition but crystallizes in the cubic system and has properties different from the industrial product. The ordinary hexagonal variety of crystal has a hardness on the Mohs' scale of scratch hardness just above fused alumina or corundum and considerably below the hardness of the diamond. In 1891 silicon carbide was the hardest synthetic material which had ever been made. The discovery of boron carbide in 1929 took this distinction from silicon carbide.

Other properties of silicon carbide, in addition to its hardness, served to develop a large commercial market for it. The crystals are mechanically strong, have high thermal conductivity and desirable fracture characteristics which make them extremely useful in grinding wheels and in abrasive paper and cloth products. The high thermal conductivity, taken with the resistance to fluxing, fusion or oxidation of the material, makes it valuable in the manufacture of high-temperature bricks and other refractory products such as muffles, tubes and saggers. Silicon carbide also has unique electrical properties, including a high negative temperature coefficient of resistance. In the cold, silicon carbide might be classed as an insulator; as it is heated up to higher temperatures it becomes more conductive, so that at 2,000° C. it is as conductive as graphite. This places it in the class of semiconductors which have many special uses.

Industrial Production.—The total production of silicon carbide in the United States and Canada in the mid-1960s was in excess of 100,000 tons annually. Of this amount, roughly 60% was used for abrasives and 40% for refractories and other special uses. The total production of synthetic abrasives of all types during this period was about 400,000 tons annually, so that it is apparent that while silicon carbide was still an important abrasive material, it no longer represented the chief abrasive manufactured with electric power. This distinction had passed to fused alumina or corundum, which finds its chief use in the cutting and grinding of steel and other high tensile strength products. Silicon carbide is used mostly for the shaping of low tensile strength materials such as cast iron, bronze, glass and marble.

The commercial manufacture of silicon carbide is accomplished in much the same way throughout the world from the two basic raw materials, glass sand (pure SiO_2) and high-grade coke (low-ash petroleum or pitch coke). Most of the world production is localized in the Niagara district of the United States and Canada

where electric power from Niagara falls is available for the large requirement of electrical energy needed in the production. About 4 to 5 kw.hr. are consumed for the production of each pound of silicon carbide. The other large producing areas in the world are in Norway and in Czechoslovakia.

At mid-20th century the electric furnaces used for the production of commercial silicon carbide were similar throughout the industry and were much the same as the original furnace described by Acheson in his original patent. A typical furnace is a large brick box ranging in size from 20 to 50 ft. in length and from 10 to 20 ft. in width and 10 ft. deep. The refractory brick box serves only as a container to hold the crude mixture which consists of ten parts of glass sand and six parts of high-grade coke. Some variable amount of wood sawdust is added to the mixture to change its thermal conductivity and gas permeability characteristics. This loose granular mix is piled into the box until it is half full, and a trench is cut lengthwise in the loose mixture. This trench is filled with coarse metallurgical coke particles which are in contact with large carbon electrodes at each end of the box. This granular core is used ordinarily as a starting resistance to bring up the centre zone of the mixture to the reactive temperature which is from 2,000° to 2,600° C. Because of the long resistor and the many contacts between the carbon particles, a high voltage (up to 500 v.) is needed for starting the furnace, but as soon as some reaction takes place and a sheath of silicon carbide forms around the outside of the central resistor, the conductivity of the resistor is increased. This increase proceeds during the course of the run so that the voltage continually must be adjusted downward. As the current goes up to as high as 40,000 amp. the voltage must be adjusted down to a low of 75 v. Furnaces normally require from 1,000 to 3,000 kw. of power input to produce the abrasive efficiently. Expensive electrical equipment is necessary to control these large blocks of power through the required operating range. Production stops long before the central developing ingot of silicon carbide approaches the walls of the brick container because there is no known refractory which can stand the high temperatures involved in this furnace operation. The product is made in an envelope of itself. The chemical reactions liberate great volumes of carbon monoxide; in fact 1.4 tons of carbon monoxide is produced for every ton of silicon carbide recovered. This gas permeates the loose mix and burns on the outside of the furnace, aiding somewhat in the reduction of heat losses from the container.

SILICONE, any one of a group of synthetic polymers (*see* POLYMERIZATION) composed of the elements silicon, carbon, hydrogen and oxygen. They are usually noted for ability to withstand comparatively high temperatures without decomposing.

Silicone polymers may take the form of oily liquids, resins or rubbery solids (elastomers), depending upon their chemical composition and the average size of the molecule. The commercial types of silicone resin and rubber are usually designed to have the greatest heat stability consistent with strength, adhesion and the other necessary physical properties, but some types are designed especially for fluidity or flexibility at very low temperatures or for some other special property such as solvent resistance. All types are quite inert chemically; they are indifferent to dilute acids and most reagents except strong alkalies and hydrofluoric acid, both of which are capable of destroying their basic structure.

The name "silicone" was coined by F. S. Kipping of University College, Nottingham, Eng., to describe compounds of silicon which were analogous to the organic ketones (*see* ALDEHYDES AND KETONES). A silicone therefore designates a substance which has a composition corresponding to two organic groups or radicals bonded to a silicon atom which in turn is linked to oxygen; it might equally well be described as an organosilicon oxide. The analogy between silicones and ketones begins and ends with the empirical composition, however, for the two groups of compounds are very different structurally. The ketones have simple molecules corresponding to their elementary composition, whereas the silicones always have polymeric structures in which the unit of composition is repeated many times in a single molecule. A silicone polymer may therefore be pictured as a chain or network of alternate silicon and oxygen atoms bearing appropriate organic groups attached to the silicon atoms:

$$\begin{array}{ccccccc} & R & & R & & R & \\ & | & & | & & | & \\ - & Si & -O- & Si & -O- & Si & -O- \\ & | & & | & & | & \\ & R & & R & & R & \end{array}$$

The organic groups R modify what otherwise would be a purely inorganic silicon oxide or silica glass, and provide the desired degree of flexibility, plasticity, or even fluidity. The kind of organic group and its size in relation to the silicon-oxygen framework thus has an important influence on the properties of the silicone polymer. In practice, the R groups are almost always methyl groups (CH_3-), but occasionally phenyl (C_6H_5-) or ethyl (C_2H_5-) groups.

Silicones usually are made by hydrolyzing the simpler organosilicon chlorides or ethers and condensing the products to polymeric form. The starting material is silica in the form of sand or quartzite, which by one of several methods is chemically combined with organic groups. In the Grignard method, silicon tetrachloride is prepared from the silica and is allowed to react with approximately two equivalents of organomagnesium chloride (Grignard reagent, *q.v.*) in an ether solvent to form a mixture of organosilicon chlorides from which the pure compounds are separated by distillation:

$$RMgCl + SiCl_4 = RSiCl_3 + MgCl_2$$
$$2RMgCl + SiCl_4 = R_2SiCl_2 + 2MgCl_2$$
$$3RMgCl + SiCl_4 = R_3SiCl + 3MgCl_2$$

In the direct method, elementary silicon is prepared by reduction of the silica and is caused to react directly with an organic chloride in the vapour phase and in the presence of a catalyst to form a mixture of organosilicon chlorides, from which the pure constituents again are distilled:

$$2RCl + Si = R_2SiCl_2, \text{ etc.}$$

In a third method, ethylene is absorbed by dichlorosilane made from silicon:

$$2HCl + Si = H_2SiCl_2$$
$$H_2SiCl_2 + 2C_2H_4 = (C_2H_5)_2SiCl_2$$

Pure organosilicon chlorides from any of these methods become the intermediates from which the silicone polymers are made.

Silicone resins are made by hydrolyzing a mixture of monosubstituted and disubstituted silicon chlorides, sometimes in a solvent. Reaction with the water replaces the chlorine with hydroxyl groups, and the hydroxides intercondense to form a polymer:

$$R_2SiCl_2 + 2H_2O = R_2Si(OH)_2 + 2HCl$$

$$xR_2Si(OH)_2 = \left[\begin{array}{c} R \\ | \\ -Si-O- \\ | \\ R \end{array}\right]_x + xH_2O$$

Silicone resins prepared in this way usually are applied in the form of a solution or varnish. After the solution has been applied to the desired surface the solvent is evaporated and the resin is cured by heat, sometimes with the assistance of curing agents or catalysts. The final product has a molecular structure in which the chains of silicon and oxygen atoms are interconnected or cross-linked by extra atoms of oxygen on the monosubstituted silicon atoms, and is therefore comparatively insoluble and infusible. Such resins are useful as insulating and protective coatings, and some are serviceable at temperatures up to 600° C. for extended periods.

Silicone oils may be made by preparing linear polymers of dimethylsiloxane of a length corresponding to the desired viscosity and vapour pressure. In order to prevent further change of molecular weight through condensation, the chains are blocked by attaching unreactive groups to the ends. Such chain-blocked oils show little change of viscosity with temperature and so are useful at low temperatures as well as high. They do not oxidize or sludge as readily as do hydrocarbon oils, and they are suitable as dielectric media because they have low electrical losses over a wide range of temperatures and frequencies.

Silicone elastomer is made by hydrolyzing pure dimethyldichlorosilane and extending the resulting linear polymers to very high molecular weight, so that the chains consist of thousands of dimethylsiloxane units. Such high polymers have elastic properties, and if they are milled with inorganic fillers and curing agents, the compounded material can be cured or vulcanized to a rubbery product.

Like silicone oil and resins, silicone rubber can be utilized at temperatures both above and below those permissible for the organic elastomers, both natural and synthetic.

Very thin films of silicone polymers also are formed *in situ* by reaction of the organosilicon chlorides with the adsorbed water on cellulose or glass, and the films so formed cause the surface to become highly water-repellent. Such a film is strongly bound and can be removed only by chemical action or by severe abrasion, but may readily be cleaned by alcohol or by solutions of wetting agents.

The process is useful wherever paper, cloth or glass is to be made water repellent.

SILICON STEEL: *see* MAGNETISM: *Permeable Materials;* STEELS, ALLOY.

SILICOSIS is a chronic, incurable disease of the lung produced by the inhalation of fine particles of silica, the chief mineral constituent of sand and of many kinds of rock. An occupational disease, it is one of the many forms of pneumoconiosis (*q.v.*) afflicting persons who work in dust-laden air. The disease rarely occurs with exposure of less than two years' duration and rarely to dust concentrations of less than 6,000,000 particles per cubic foot (about 210,000 per litre) of air. Only particles less than 10 microns ($\frac{1}{2,500}$ in.) in diameter reach the lung and particles one to three microns in diameter are the most injurious. Combined forms of silica (silicates) do not produce damage and are dangerous only because of the percentage of free silica they may contain. Actually, inhaled inert dusts may modify the effects of silica.

The disease is characterized by whorls of fibrous tissue that form about aggregates of silica particles. These foci gradually enlarge to form fibrotic masses involving both the functional tissues of the lung and the draining lymph nodes. Symptoms are shortness of breath followed later by cough, tightness across the chest, and weakness. Diagnosis is based on the X-ray appearance of the lungs and a history of exposure to silica dust. The most frequent and important complication is superimposed tuberculosis. Although silicotuberculosis is still a serious disease, prognosis has been improved by the advent of tuberculosis chemotherapy.

Occupations in which silicosis is a hazard include mining, stonecutting, grinding, polishing, glassworking, sandblasting, and pottery, steel, and abrasive-soap manufacturing. Since there is no specific treatment for silicosis once it is established, control of the disease lies in prevention. The use of proper ventilation, wet-grinding techniques, and face masks to filter out dust has helped to lessen the incidence of silicosis. (W. R. By.)

SILISTRA (ancient DUROSTORUM), the chief town of the *okrug* of that name in northeastern Bulgaria, lies on the right bank of the Danube (where it forms the frontier with Rumania) and 65 mi. (105 km.) ENE of Ruse. Pop. (1963 est.) 28,736. To the south and southeast are the remains of the old fortifications. The town manufactures bricks and tiles, furniture, rush matting, and cotton textiles. Its river port has a large silo and exports mainly cereals. Silistra is linked by rail with the Ruse-Varna line, and the Constanța-Bucharest, Rum., road passes through it.

The Romans founded a military camp at Durostorum (later Dorostolum; medieval Dristra; Bulgarian Drstr or Drustur) in the late 1st century B.C. or early 1st century A.D. It became one of the important towns of Moesia Inferior (*see* MOESIA). Its importance was maintained under the Byzantines and Bulgars (*see* DOBRUJA). For some time in the 10th century it was apparently the seat of the Bulgarian patriarch, and the emperor John I Tzimisces defeated the Russian prince Svyatoslav I there in 971. Under the Turks (who finally gained possession of it by 1420) Silistra was an important fortress in the strategic Turkish quadrilateral Silistra-Ruse-Kolarovgrad (Shumen)-Varna. The Russians attacked Silistra several times in the 19th century. The town was assigned to Bulgaria in 1878 and to Rumania, after the second Balkan War, in 1913 as part of the southern Dobruja. It was returned to Bulgaria in 1940. (*See* also BULGARIA: *History.*)

SILISTRA OKRUG is a fertile agricultural region and produces cereals, beans, sugar beet, and grapes; stock is also raised. Area 1,108 sq.mi. (2,870 sq.km.); pop. (1962 est.) 170,300. (AN. BE.)

SILIUS ITALICUS (in full TIBERIUS CATIUS ASCONIUS SILIUS ITALICUS) (25 or 26–101), Latin epic poet, was the author of a long epic entitled *Punica,* an account in hexameter verse of the second war of the Romans against the Carthaginians (218–201 B.C.). Silius was an advocate of distinction in his early years, but he soon took to the public service and was consul in A.D. 68 (the year of Nero's death). His life thereafter is described by the younger Pliny in one of his letters: "he won repute by his proconsulship of Asia, and obliterated by the praiseworthy use he made of his leisure the stain he had incurred through his former exertions" (presumably as an assistant of Nero). "In dignity and contentment, avoiding power and therefore hostility, he outlived the Flavian dynasty, keeping to a private station after his governorship of Asia."

Silius was a rich man and able to indulge his tastes as a patron of literature and the arts. He so venerated both Virgil and Cicero that he bought for himself Virgil's tomb at Naples (which he restored) and Cicero's estate at Tusculum. In later life he imitated both, the former in writing epic, the latter in discussing philosophy with his friends, such as the poet Martial, Epictetus, who thought well of him as a philosopher, and Cornutus, the Stoic, who dedicated to him a commentary on Virgil. The Stoicism of Silius is not as marked in his epic as that of Lucan in his, but it is discernible, as one might expect, in a story of long and embittered warfare; and it was clearly to be seen in his life, for at the age of 75 he discovered that he was suffering from an incurable disease and starved himself to death.

The *Punica,* the only work he is known to have committed to writing, is the longest epic in Latin literature, comprising over 12,000 lines. It deals with the second only of the Punic wars, though the story of Regulus (*q.v.*) appears in it as a digression. Silius draws heavily on the historian Livy for his material. For the most part he sticks well to his story and conscientiously describes all the six great battles of the war. The "details of slaughter" (as his translator J. D. Duff puts it) are often repulsive and the catalogues of armies monotonous. It is very imitative of Virgil's *Aeneid* both in its form and in its mythology. The gods take part, for example, and Juno frustrates the Romans just as she does the Trojans in the *Aeneid.* It lacks the poetry and the drama of Virgil, and the metre is monotonous and the style sometimes repetitive. The epic has indeed been harshly judged by its critics and has been rarely edited since the 18th century, but Silius can tell a story well and in simple language, far purer than the overdecorated style of other Latin poets of the Silver Age; and his accounts of military matters (*e.g.,* of the operations of siege engines) often bear the stamp of experience. His characters are mostly rather wooden, but his Hannibal is drawn with some dramatic skill and steals the place of hero from Scipio. Of the minor characters the best drawn are Fabius Cunctator,

an evident copy of Lucan's Cato, and Paulus, the consul killed at Cannae.

The last three books show signs, as well they might, of fatigue; but posterity should be grateful for about half a dozen beautiful pieces of verse, mostly in dramatic scenes of war.

The poem was discovered in a manuscript in 1416 or 1417; from this manuscript, now lost, all existing manuscripts are derived. There were two *editiones principes* (1471). Other editions are by D. Heinsius (1600); J. C. T. Ernesti (1791); L. Bauer, "Teubner Series" (1890); J. D. Duff, with English translation, "Loeb Series," two volumes (1934).

For his life the authorities are Pliny, *Epistles*, iii, 7; Tacitus, *Histories*, iii, 65; with frequent references in Martial. (An. K.)

SILK, the thread and cloth made from the fibre produced by silkworms. A variety of insects, including spiders, produce silk but most of these substances—a spider's web, for example—are too adhesive and fragile to be suitable for textiles. The fibres used for commercial silk manufacturing are produced mainly by the mulberry silkworm of the orient, *Bombyx mori*, and a few other closely related members of the same family (Bombycidae), in the form of a cocoon that acts as a shell to enclose and protect the insect during its period of transformation from caterpillar to chrysalis to moth.

The breeding and cultivation of silkworms is termed sericulture. Silk manufacture includes all phases of silk processing, from the production of thread or yarn directly from the cocoon to the finishing of the woven or knitted fabric.

This article is divided into the following main sections:

I. HISTORY

The origin of silk is so ancient that the course of its early development is to be found only in legend and fable. The industry undoubtedly began in China, where, according to native record, it has existed from antiquity. It became important in the Chinese economy under the emperor Huang Ti (2640 B.C.), whose empress, Hsi Ling Shi, is said to have made sericulture fashionable by giving it her personal attention. Chinese literature testifies to the fact that royalty and nobility followed her example by cultivating mulberry trees, raising worms, and reeling silk. The empress herself is credited by the Chinese with the invention of silk reeling and the loom. Silk was used as a medium of exchange within the country and also was exported. The Chinese zealously guarded the methods of production, and under imperial decree, disclosure of any of them meant death by torture for the informer. Thus, many centuries passed before any knowledge of the source or manufacture of this fabulous fabric spread, and when it did, around A.D. 300, it was through Japanese initiative. The *Nikongi*, one of the most ancient Japanese histories, relates that some Koreans were sent by Japan to China to bring back weaving instructors. The Koreans returned to the Japanese court with four Chinese girls, who taught their art first to royalty and then to the people. A temple was built at Settsu (Osaka Province) in honour of these four pioneers of the industry that eventually helped raise Japan to a world power.

Ancient Sanskrit literature refers to an Indian silk industry. The word used could have denoted either weaving of silk fabrics or, more probably, the manufacture of silk garments. Even at that early date the rajas of that country were extremely partial to its opulence. According to an old legend, in about 140 B.C., silkworm eggs and mulberry seeds were carried to Khotan, in an old southern Chinese province near the border of India, hidden in the lining of the headdress of a Chinese princess who had gone there to be married and wanted her beautiful native silks at the new court. This may have made possible the beginning in India of the actual breeding and rearing of silkworms. Since sericulture now is known to have been established in India first between the Brahmaputra and Ganges rivers, it seems credible that it was introduced overland from China. From the Ganges Valley, sericulture moved slowly west into Persia and central Asia.

The Old Testament has two incidental references to silk, in Ezek. 16:10, 13. Aristotle, in his *Historia animalium*, described the silkworm as "a great worm which has horns and so differs from others. At its first metamorphosis it produces a caterpillar, then a bombylius and lastly a chrysalis . . . all these changes taking place within six months. From this animal, women separate and reel off the cocoons and afterwards spin them. It is said this was first spun in the island of Cos by Pamphile, daughter of Plates." Long before this raw silk probably had been imported by Cosians and woven into *coa vestis*, a gauzy, sheer fabric for which the island was famous in antiquity.

Toward the beginning of the Christian era, raw silk began to be exported from the East to Rome. When it first appeared there, silk was of enormous cost—it was literally worth its weight in gold—and its use by men was considered effeminate. Allusions to silk became common in classical literature; although these references show familiarity with the fabric itself, they are vague and inaccurate as to source. It was believed by some to be a fleece from a bush or tree, by others a fibrous substance of the inner bark of a tree. Even the naturalist Pliny the Elder knew nothing more about the silkworm than Aristotle did.

By the 2nd century A.D. the silk-weaving industry flourished in Egypt, Syria, and Palestine and by the 4th it had developed in Constantinople and Persia. When the seat of the Roman Empire was moved to Constantinople, the emperor Justinian, seeing the great commercial potentialities of silk, took steps to create a monopoly, setting up looms within the imperial palace. He also attempted to divert the thriving silk trade from the Persian route along which it was then brought into eastern Europe, but he failed in this endeavour. He was able, however, to persuade two Persian monks who had lived in China to return there and smuggle silkworms to Constantinople in the hollows of their bamboo canes (*c.* A.D. 550). These few hardy silkworms were the beginning of all the varieties that stocked and supplied European sericulture until the 19th century.

The silkworm and its product flourished in the West during the Middle Ages. Byzantine silks, widely used for ecclesiastical vestments and altar cloths, became world famous, and feudal lords adopted the cloth for themselves, their ladies, and their courts. Knight crusaders and other military adventurers carried back to Europe silk from the Middle East, with Arabic patterns and colours quite different from anything seen up to that time. More significantly, from the point of view of the European industry, the Moors, who had conquered Sicily and parts of Spain, established sericulture there. When Sicily was taken by the Normans in the 11th century, Roger I, the first Norman king, improved the quality and increased the production of Sicilian silk, the use of which spread north to the mainland. Sericulture and silk manufacture were profitable, and the industry was encouraged by the nobility of medieval Florence, Genoa, Milan, and Venice. Under royal patronage these cities became famous for silks and gained a prominence never completely relinquished. In France, silk weaving was started at Tours in 1480 under Louis XI, and in 1520 Francis I brought silkworm eggs from Milan to be reared in the fertile Rhône Valley. It remained, however, for J. B. Colbert, minister of finance under Louis XIV, to establish the industry firmly in that country by offering premiums for the planting of mulberry trees and by otherwise stimulating local French interest in sericulture.

Silk manufacture began in England in the 14th century, but

the first real impetus to the British industry came in the 16th century with the emigration of large numbers of skilled Flemish weavers, a result of the prolonged war between the Netherlands and Spain. James I was interested in the industry and made many attempts to stimulate mulberry planting and silkworm rearing in Britain and in the colonies. A second wave of highly skilled immigrants followed the revocation of the Edict of Nantes in 1685; most of these French Huguenot weavers settled in an area in London known as Spitalfields, where a guild of silk weavers had been formed in 1629. In 1713 English silk weavers petitioned parliament for a higher tariff on the importation of silk fabrics, because French silks could be bought in England at prices lower than those prevailing for the domestic product. Stressing the economic importance of their industry, the English weavers cited the manufacture of black silk for hoods and scarves, which had been unknown in England 25 years before and which had grown to an annual yield of £300,000 sterling. At this time the silk industry in England also had to depend on continental Europe for its supply of thrown silk for weaving. (Throwing is a vital intermediate process of silk manufacture.) The first English throwing mill was built in Derby in 1719 by Sir Thomas Lombe; plans for it are said to have been obtained by his half brother John Lombe, who disguised himself as a common workman, gained entrance into an Italian mill, and smuggled out drawings of the machinery used there. In 1825 the British, Irish and Colonial Silk Company, with capital of £1,000,000, was formed to introduce silk production into Ireland. It was a dismal failure. Despite these various efforts, sericulture never became important in British industry.

Sericulture was introduced into the Western Hemisphere in 1522, under Hernán Cortés, in Mexico. Mulberry trees were planted and eggs were brought from Spain, but the industry died out before 1600. In 1609 James I tried to reestablish the silkworm in the New World, but the attempt failed because of a shipwreck. Ten years later a determined effort was made to implant sericulture in Virginia. Laws were passed to stimulate the industry's development, which was bolstered further by bounties and rewards. Detailed instructions on the care of the worms and the raising of trees were sent to the colonists. One such booklet published in London in 1620, *OBSERVATIONS To Be Followed, For the making of fit roomes to keepe Silk-wormes in: As also For the Best Manner of Planting of Mulbery trees to feed them*, concluded with the following:

> It is a thing well knowne, that a few Silk-wormes, fed at large, and ease, make farre more silke than a greater number, pent in narrow and ill-favoured roomes. No ill smels must come neere them, they must be kept sweet, and oft perfumed: therefore having such store of sweet-woods in Virginia as you have there, you shall do well to make their roomes and tables of these woods: sweet sents being a thing most agreeable to them. Bee carefull to doe things curiously and thorowly well for them at the first, for your more plentifull and certain gaine after: considering the charge to you is all one: and a thing once wel done, they say, is twice done, which will thereby also bring you twice double profit, with long continuance.

Britain continued to offer rewards of various kinds to the American colonies for silk cultivation. At the onset of the American Revolution, Benjamin Franklin and others were trying to establish a silk-spinning factory at Philadelphia, Pa. After the war, bounties were offered by several of the states, the first by Connecticut in 1783. About 1838 a frenzied speculative mania for sericulture developed in the United States, caused principally by a promoter who extolled the suitability of the South Sea Island mulberry tree for feeding silkworms. So intense was the fever that all kinds of crops were uprooted to make room for plantations of the new golden mulberry. In Pennsylvania, $300,000 was paid for plants in one week; frequently, young trees were sold two and three times in a few days at steadily increasing prices. Within a year, the falsity of the claims became apparent, and the speculation collapsed.

Sporadic efforts to establish a silk industry in the United States continued. The next peak of interest followed the tremendous increase in the use of silk after World War I. Prices of raw silk rose steadily in the United States from $3.64 a pound in 1914 to $21 a pound in 1919. An intense effort was made in California to produce larger cocoons and more frequent crops. The cocoons raised were superior, but the local cost of hand reeling was prohibitive, and the volume was not sufficient to make it economically profitable to have the work done in Japan. Another attempt at sericulture was initiated in the United States by a promoter who talked of meeting world competition and spread the vision of large profits from the production of a silk filament precoloured by direct injection of dye into the silkworm. Louisiana, Florida, and Canada witnessed scenes of mounting activity in the purchase of mulberry trees and rainbow-hued silkworms. Newspaper accounts implied that fortunes were to be made. A year later, investors were unable to find buyers for their cocoons. Once more sericulture in the United States had proved impracticable.

In Iran the antinarcotic division of the League of Nations sought to replace the growing of the opium-producing poppy with sericulture; that country was one of the original hosts to the silkworm and was believed to have natural characteristics favourable for it. The industry was started, and in 1939 Iranian government representatives were sent to New York in an endeavour to sell the fabrics in the United States, which was the largest user and importer of silk, but the types of cloth, styling, and sparse production made the Iranian product unacceptable to the U.S. market. At about that time, U.S. manufacturers turned again to China, original source of silk. It was found that production methods there were antiquated, so the silk industry in the United States subscribed a large fund to initiate the study of sericulture in three of the missionary colleges in China. Land was bought for mulberry orchards, new equipment was installed in modern buildings, and courses were planned to teach the latest methods. The Chinese were disinclined to change their methods, however, since they found that even without doing so they could continue to sell their production to Europe. This, coupled with the increasing domestic upheavals in China, finally resulted in the discontinuance of attempts by the Americans to modernize the Chinese silk industry.

India was another experimental field for the commercial development of silk. Interest also was shown by officials in the Black Sea area of the U.S.S.R., in Greece, and in Spain. During World War II silk was grown and spun in Brazil, which has climatic conditions favourable for sericulture. Despite these diverse efforts, the principal source of supply continues to be Japan, which has dominated the world market since 1865.

Silk can be produced and marketed profitably where the climate is favourable and where labour is cheap, abundant, and skilled. The rising standard of living the world over makes it necessary for the industry to continue its search for additional mechanization of the various processes in order to keep the product competitively priced and a great deal of work to this end was being done in Japan in the 1960s.

Japan is by far the greatest consumer of raw silk, using approximately ten times as much as the next largest consumers, the United States, Italy, and India. (Figures are not available for China and the U.S.S.R.) In 1938, 80% of the silk consumption in Western countries went into hosiery. After World War II stocking manufacturers turned to nylon and the U.S. ceased to be the leading silk consumer. Silk consumption by Japan and certain other countries was, by the 1960s, back to prewar levels, but for cloth alone, which had thus made striking advances.

In spite of the progress in man-made fibres for clothing since the end of World War II, silk remains the first choice for luxurious and elegant clothes the world over. In addition to the traditional types of silk fabric used for women's evening, cocktail, and all "special occasion" dresses, "wild silk" fabrics such as shantung and Thailand silk enjoyed a vogue in postwar years. Silk suitings for both men and women also proved popular. In the lower price ranges, silk figures very little, since a cheap silk fabric does not wear well and does not have the easy-care characteristics of similarly priced fabrics in man-made fibres. An exception is "Jap silk," a lightweight, closely woven, strong, and relatively inexpensive silk which is widely used for linings.

II. SILK-SPINNING INSECTS

1. Cultivated Silkworms.—*Bombyx mori.*—The mulberry leaf-feeding silkworm, *Bombyx mori*, the principal source of silk,

belongs to a family of Lepidoptera that includes some of the largest and handsomest moths and butterflies. *B. mori* itself is an inconspicuous moth, ashy white in colour, with the male's body less than one-half inch long and the female's longer and heavier. Its wings are short and weak; the fore pair are slightly curved and the hind pair do not reach the end of the body. The larva, black when newly hatched, turns to cream colour, grows to 3 or 3½ in. in length, and is slender in comparison with others of its family. The second thoracic ring is humped, and there is a spinelike horn at the tail. The silkworm produces one generation annually where the seasons are defined, for example, in Europe and the Middle East. In Japan reproduction takes place two or three times during the year, and in parts of India and China it is almost continuous. The quality of silk produced by the silkworm is in inverse ratio to the number of hatchings.

The silk glands, which wind along the underside of the caterpillar's body and which produce fibroin, consist of two long, pipelike sacs called hind-silk glands. These empty into two S-shaped tanks called mid-silk glands that ripen the fluid. Toward the forward part of the body, the glands again become thin and are known as fore-silk glands. Near the head the two glands open through a common orifice, the spinneret, on the underlip of the caterpillar. As the caterpillar reaches maturity, the glands become gorged with a clear, viscous fluid, which is used to spin the cocoon. As this spinning fluid (the two strands of fibroin) is ejected through the spinneret, it is joined by a second secretion, sericin, from another set of glands located at the opening. The sericin solidifies immediately upon contact with the air, and the double fibre emerges as a single filament. The cocoons are hard, compact shells, oviform in shape and frequently constricted in the middle, with straggling, flossy filaments on the exterior and the interior layers so densely agglutinated as to resist complete unwinding. The fibres vary from white to yellow in colour. With variations according to sex and species, the cocoons measure from 1 to 1½ in. in length and ½ to 1 in. in diameter and weigh 15 to 50 gr.

Within 10 to 12 days after the completion of the cocoon, the enclosed insect is ready to emerge. It moistens one end of the cocoon with enzymes that partially dissolve the fibres, enabling the creature to push aside the filaments and emerge as a perfect moth. The sexes mate almost immediately; the female lays 500 or more eggs within four to six days and soon dies. Under improved methods, the sericulturist destroys the male immediately, as it is believed multiple matings by the male are deleterious to the quality of the ultimate silk.

Other Bombyx Species.—Numerous allies of the mulberry silkworm spin usable cocoons and produce what is known commercially as wild silk. Six species of *Bombyx*, differing from *B. mori* but also mulberry-feeding, have been domesticated, more or less, in India. Included in this group are *B. textor* of Bengal, a large species having one generation yearly and producing a soft, flossy cocoon; *B. sinensis*, producing several generations annually and making a small cocoon; *B. croesi*, *B. fortunatus*, and *B. arracanensis*, all yielding several generations annually and forming reelable cocoons. Many other mulberry-feeding Bombycidae have not come under cultivation.

2. Wild Silkworms.—The family of giant silkworms (Saturniidae) includes several species that produce a silk that is commercially marketable but not so fine in quality as that spun by *Bombyx mori*. One of the most important moths yielding wild silk is *Antheraea pernyi*, an oak-leaf feeder native to Mongolia. From it is derived the brownish tussah silk imported extensively into Europe. Closely allied to it is *A. mylitta*, which feeds on leaves of the jujube tree in India and spins a large, compact silver-gray cocoon. *A. assama* is domesticated to some extent in its native Assam in India.

Cultivation in Europe of the Japanese *A. yamamai*, another oak-leaf feeder, was disappointing: the eggs, brought to Europe in the early 1860s, were found to hatch at a time when oak leaves were not available, and the silk did not compare with that from the domesticated mulberry silkworm. The mezankoorie moth of Assam also yields a valuable cocoon, as does *Attacus atlas*, an

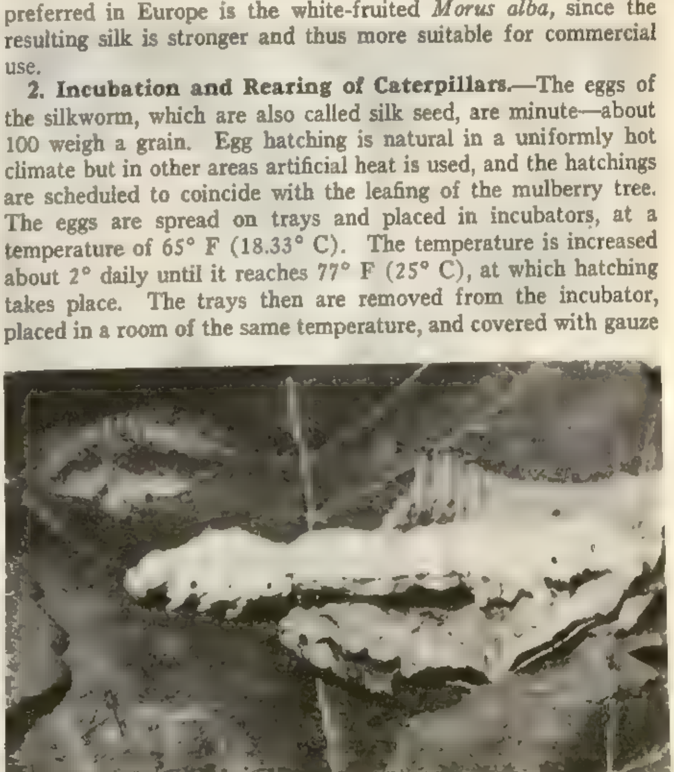
FIG. 1.—RACKS CONTAINING THE FEEDING SILKWORMS

omnivorous feeder found throughout India, Ceylon, Burma, China, and Java. *Samia cynthia*, which feeds on a variety of plants, including ailanthus and castor oil plant, spins a loose, flossy cocoon, orange-red or sometimes white.

III. SERICULTURE

1. Food Supply.—The first requirement of sericulture is a stock of mulberry trees adequate to feed the silkworms in their larval stage. The soil in which the mulberry trees grow and the age and condition of the trees are important. An elevated position with dry, friable, well-drained soil produces the best-quality leaves. Many species are cultivated, and, as they have grown for at least 3,000 years, they show the complex variations of most cultivated plants. In Japan, pruning produces more luxuriant growth and, over a period of time, has reduced the height of the trees, obviating the need of ladders in harvesting. The mulberry preferred in Europe is the white-fruited *Morus alba*, since the resulting silk is stronger and thus more suitable for commercial use.

2. Incubation and Rearing of Caterpillars.—The eggs of the silkworm, which are also called silk seed, are minute—about 100 weigh a grain. Egg hatching is natural in a uniformly hot climate but in other areas artificial heat is used, and the hatchings are scheduled to coincide with the leafing of the mulberry tree. The eggs are spread on trays and placed in incubators, at a temperature of 65° F (18.33° C). The temperature is increased about 2° daily until it reaches 77° F (25° C), at which hatching takes place. The trays then are removed from the incubator, placed in a room of the same temperature, and covered with gauze



BY COURTESY OF THE JAPAN SILK ASSOCIATION

FIG. 2.—SILKWORM FEEDING ON MULBERRY LEAVES

or perforated paper. Finely chopped mulberry leaves are spread over this covering, and the larvae wiggle through the openings to begin feeding.

The place in which the caterpillars are reared must be scrupulously clean, disinfected, lime-washed, and well ventilated. A vast number of newly hatched larvae may be kept in a small space, but as they grow, they and their food require increasing room. A common method of maintaining them during feeding is by means of trays stacked on shelves about 3 ft. wide, with adequate passage on all sides. The shelves are constructed of light scantling or bamboo, beginning about a foot from the floor and running at two-foot intervals, as high as a person can conveniently reach.

After three or four days the caterpillars are fed whole leaves. They are voracious during the feeding period, which continues for about 42 days, interrupted by four 24-hour intervals of sleep. On awakening from these sleeps the caterpillars slough their skins and then resume feeding. After the last sleep they start a final 10-day period of feeding. In the course of the total feeding period, they consume about 20 times their own weight in leaves and grow from a length of less than $\frac{1}{16}$ to about 3 in.

Studies have indicated that one ounce of seed eggs produced 30,000 to 35,000 silkworms, which consumed one ton of ripe leaves. From this seed 130 to 140 lb. of fresh cocoons were produced, with an ultimate yield of 12 lb. of reeled silk.

3. The Cocoons.—The caterpillars show they are ready to spin their cocoons by raising the forepart of the body and waving it slowly from side to side. Provisions now are made for proper spinning. A commonly used method involves trays with compartments about $2 \times 2\frac{1}{2}$ in. in size, each of which accommodates one caterpillar. The caterpillars are tossed lightly into the compartments, and the trays are fastened together at intervals, one above the other, to form mounts. The mounts are raised from the floor and revolved slowly for 60 hours, the time required for the caterpillar to complete its cocoon. The temperature of this room is kept at about 73° F (22.78° C) and the humidity not higher than 70%. After an additional seven days, during which period the caterpillar changes to a pupa, the cocoons are harvested.

If the silkworms were overcrowded during the time of spinning, two or more may have spun a common cocoon, which is impossible

FIG. 3.—(LEFT) SILKWORM SPINNING ITS COCOON; (RIGHT) PUPA INSIDE FINISHED COCOON

to put through the usual reeling processes because of the intermingling and interweaving of the fibres. Such cocoons, called doupions, are set aside for special handling. The silk so processed produces a slubbed yarn, and, when such textures are in demand, doupion cocoons are produced deliberately.

In the harvesting, all the cocoons, other than the doupions and those selected for reproduction of eggs, are treated to preserve them intact for reeling—that is, the chrysalis must be killed without damage to the cocoon. In primitive sericulture this was done by exposure to the sun, but in many cases the heat failed to kill the pupa before it emerged as a moth, resulting in a damaged cocoon. Another method is suffocation by steam, in which the cocoons are placed in drawers over steam for eight or ten minutes

FIG. 4.—(LEFT) FEMALE MOTH LAYING EGGS; (RIGHT) LARVAE HATCHING

and then are turned and air-dried for six weeks to two months. The process is time consuming and requires an excessive amount of hand labour. The safest, most practical, and widely used method is suffocation by hot air, using an oven built of brick or concrete and equipped with a series of eight moving belts. The temperature in this oven at the top is 210° F (98.89° C), graduated to 140° F (60° C) at the bottom. Cocoons are fed into a hopper at the top and by means of the belts pass to the bottom, where they drop into canvas bags. Passage of the cocoons through the whole process requires seven or eight hours, during which time the chrysalises are killed and the cocoons are dried, ready for reeling.

4. Selection of Eggs for Reproduction.—Production of seed eggs is carefully controlled to reduce the great risk of propagating diseases. In Japan, the largest and most important source of these eggs, producers can operate only under government licence and control; regulations are stringent and are enforced assiduously. Symptoms of any of the dreaded silkworm diseases are readily recognized by adept sericulturalists, and moths that show signs of disease at any stage of growth are destroyed. Female moths selected to lay eggs are placed in a special room, on individual, flat, eight-inch squares of cheesecloth. When the laying has been accomplished, some females, chosen at random, are destroyed and chemically or microscopically examined to ascertain that they are wholly free of disease. The eggs also are examined. If they are found to conform to government standards and regulations, they are washed, dried, and carefully packed for local distribution or shipment.

The primary aim of this phase of sericulture is the propagation of lively, disease free stock. Crossbreeding also is done to develop new varieties for specific requirements that range from higher yield of reeled silk to hardier strains for various climates.

5. Diseases.—The silkworm has been propagated for more than [illegible] years under purely artificial conditions, frequently insanitary, with the objective of securing the greatest amount of silk possible; it is, therefore, only to be expected that the [illegible] is subject to many serious diseases. Among the most fatal and disastrous of these is muscardine, caused by fungus, which is peculiarly contagious and infectious; spores of the fungus, transferred from one silkworm to the other, penetrate the skin and germinate corpuscles within the insect's body. Fortunately, muscardine has not been epidemic in many years, and in some countries is no longer considered a serious problem.

Another disease, which was first noticed near Avignon, France, in the early part of the 19th century, and was later called pébrine, manifests itself by dark spots on the skin of the larvae; eggs do not hatch perfectly; larvae are weak, stunted, fastidious in eating, and many die; cocoons are loose; and moths are feeble. In the second generation there is an increased intensity of [illegible] symptoms. The disease, thus, is hereditary, infectious, and contagious. By [illegible] French cultivators were forced to import [illegible] but, despite this measure, silk production continued to [illegible] Italy the disease was even more disastrous, and the malady [illegible] eastward to such an extent that unaffected eggs could be obtained only from Japan.

In early research on the disease, vibratory corpuscles [illegible] named for their identifier Cornelia, were found in the blood [illegible] tissue of the affected silkworms. In 1865 the French government commissioned Louis Pasteur to study the disease. He established

...these Cornelian corpuscles are parasites and are not only the ... but the cause of the sickness, and that it is transmitted ...gh heredity or contagion with diseased worms or by the ... of leaves on which the parasitic corpuscles are present. ...er concluded that the existing epidemic conditions were only ...aggeration of a normal state, and he advised selective breed... regenerate the stock. Eventually, a supply of healthy Eu... stock was reestablished, but, of all the diseases to which ...lkworm is subject, pébrine remains the most dreaded.

The ultimate filaments ... silks are thicker and more ribbon-shaped than those of ...rry silk and exhibit longitudinal striations along which the ...nts tend to split into fibrillae under any mechanical or chemical action. The fibroin of wild silks possesses properties similar to those of mulberry fibroin but is more resistant to chemical action. Sericin, also a protein, is more active chemically than fibroin, from which it may be separated by the solvent action of hot water, acid, or alkaline solution. Its composition is similar to that of fibroin, but it contains more oxygen. Like fibroin, sericin may be chemically heterogeneous. The colouring matter of yellow silk is xanthophyll, a yellow pigment related to carotene.

Silk has great powers of absorption and takes up dyestuffs at a temperature much lower than does wool. This greater capacity of absorption, perhaps higher than that of any fibre, permits silk, when dyed, to take on the brilliant colours for which it is famed. Its absorptive powers are so great that the weight of silk can be increased as much as 30% in moisture content without any change in appearance. This characteristic made it necessary to establish an international standard of 11% as the permissible limit of regain in moisture over dry weight. (E. T. A.)

V. SILK MANUFACTURE

Cocoons are manipulated to produce continuous filaments of raw-silk yarn through a process, distinctive to the silk industry, called reeling. Silk waste, the short silk fibres that are a by-product of reeling or other manufacturing operations, is spun like cotton or wool into a yarn called spun silk. Filament silk is prepared for weaving by throwing (twisting) to the extent required. After weaving, the fabric is degummed (boiled-off) and dyed or printed, unless it has been woven from yarns dyed before weaving.

1. Reeling.—The purpose of reeling is to bring together the threads from two or more cocoons (depending on the final thickness or size of thread desired) to form them into one continuous, uniform and regular strand that constitutes commercial raw silk. The process, which is extremely delicate, has been mechanized and automated; the establishment in which it is done is called a filature.

In the reeling process, the cocoons are first sorted, and doupions, pierced cocoons and any other unreelable cocoons are put aside. Those to be reeled are boiled in water for 10 to 12 minutes to soften the natural gum (sericin), which holds the filaments together. The ends of the filaments are caught, unwound and kept together by coagulation of the natural gums, so as to form a single uniform, rounded thread of raw silk that is wound on reels.

When the silk is removed from the reels, it is rewound into skeins of the desired circumference, length and weight, which then are twisted and doubled over into one-half their length and packed into small bundles called books. Some silks like doupioni are packed in full-length skeins, flat in bundles. These books or bundles are packed to form a bale weighing about 133 lb.

The size or "count" of thread of raw silk in the industry is designated by the term denier, which is the relationship of length to weight based on a standard of 4,464,531 yd. of thread that would weigh exactly one pound and is the equivalent of one denier. The denier count rises as the size or weight of the yarn increases and the yards per pound decrease in relation to this standard; therefore, a thread reeled into a size with a range of 9 to 11 denier with a mean of 10 denier would contain 446,453 yd. to a pound. The sizes of silk thread used commercially are 9/11 denier, 13/15, 14/16, 18/20, 20/22, 24/26, 28/30, 30/32 and 40/44, covering a range from approximately 446,000 yd. to the pound as noted for 9/11 denier through approximately [illegible] yd. to the pound for 40/44 denier. A thread reeled from six cocoons would result in a size of 13/15 denier having 318,000 yd. of yarn to the pound which could easily stand strains imposed by the manufacturing process.

2. Spun Silk.—The silk used to manufacture spun silk includes all kinds of unwindable raw silk. Before the introduction of machinery for spinning spun silk, nearly all the waste from reeling and silk winding was destroyed as being useless. The exception was that which could be hand combed and spun by means of the spinning wheel, a method still practised in the farm homes in India and other far eastern countries.

The raw material for spun silk is obtained principally from the lustreless and uneven thread emitted by the silkworm when it commences to spin; from the extreme outside and inside layers of each cocoon; from pierced cocoons (those from which the moth has emerged); and from waste resulting from breaking threads during the reeling and other processes.

There were, up to the beginning of the 20th century, two distinct types of spun silk: schappe silk, produced on the European continent (but never in Great Britain) and containing as much as 20% of the original gum; and spun silk, which was entirely free of the gum. Now that the use of fermentation processes has entirely died out, the term schappe silk, as used in France and Germany, is the exact equivalent of the term spun silk, neither containing more nor less gum than the other.

Spun silk, like continuous filament raw silk, is pure silk containing no extraneous matter. Spun silk yarns are used for shirtings, blouse and dress material, silk "tweed," and sewing and embroidery threads. The combings left after the processing of the spun silk fibres are called noils and are blended with other fibres or spun into coarse yarns. One cloth woven from these yarns is used for artillery powder bags; because silk is a protein fibre, it burns to a hard, beadlike ash that is easily removed from the guns, leaving no powdery ash to foul the mechanisms. Noil silk fabrics are also used for furnishing fabrics.

3. Throwing.—The silk thread, one continuous filament that has been reeled from the cocoon, does not need the combing and preparation to make the fibres parallel that is necessary in order to spin the shorter fibres of cotton and wool. The only processing needed before weaving is that of producing different effects in the finished yarn by twisting the silk thread varying degrees either to the right or left. This process is called throwing (from the Anglo-Saxon *thrawan*, "to twist"); the plant in which it is done is a throwing mill. Each twist is called a turn, and the greater the number of turns per inch, the greater the foreshortening and contraction of the thread. Many fabrics are woven with yarns containing little or no twist.

The first step in readying silk yarn for throwing is soaking the skeins in an oil-based emulsion for about eight hours at a beginning temperature of 100° F (37.78° C), to soften the natural gum, thus making the thread more pliable and workable. This done, the skeins are removed, dried and, unwound from the skein in the winding process; that is, the silk is unreeled from the skeins onto spools or bobbins. The bobbins are wound with a rapid reciprocating motion, so as to lay the thread in a crossing diamond-like pattern on the bobbin.

There are four fundamental steps in throwing: winding; doubling or plying two or more threads together with low twist, usually less than five turns per inch; twisting, increasing the turns per inch beyond the natural or that put in doubling; and, finally, skeining or coning or tubing. The twisting machinery used to perform this operation has been perfected and refined so that it is possible to twist a thread composed of six cocoon threads and which has approximately 318,000 yd. to the pound, designated as 13/15 denier, at the rate of 18,000 rpm.

The most used types of thrown yarns are tram, organzine, and crepe. Tram is two or more threads twisted together with a few turns per inch and is used for the filling or crosswise thread. Organzine is the result of doubling two or more threads, previously low twisted as single threads, and twisting them in the opposite direction, two turns per inch less or more than the twist in the single. This type of yarn is used chiefly for the warp or lengthwise thread, after being degummed and dyed in the skein. Crepe is a high-twist yarn with a range of 40 to 80 turns per inch.

Crepe twisted yarns are used in both warp and filling for such fabrics as chiffons, or as filling with raw silk, no-twist warps for opaque fabrics such as crepes. Crepe twisted yarns are twisted either to the right or left. Threads of each twist are used alternately in the fabric in both filling or warp. The crepe effect is achieved by the contrary pull of the two tightly twisted threads released from their set condition by the degumming process that causes their contraction and, therefore, shrinkage of the fabric in which they are woven. (All crepe twisted yarns are degummed after weaving.) For easier identification, the threads are tinted different colours for the left and right twists. The colours used are fugitive tints that completely disappear in the degumming of the woven fabric before dyeing.

Silk thread for sewing is manufactured as part of the throwing operation but is considered a distinct and separate branch, because some additional equipment must be used, and great care must be taken in every operation, especially spooling, to make a smooth, knotless thread.

4. Making the Fabric.—*Woven Silk.*—The first operation after throwing, or if no throwing is required, the first step after soaking the skeins, is the winding of the silk thread onto bobbins, cones, or tubes so that it may be handled in the next operation, warping.

Warping is the operation that prepares the yarns that run lengthwise in a fabric for the weaving process. It must be done most carefully, as the condition of the warp determines the efficiency with which the manufacturer can run his looms. The number of threads per inch multiplied by the width of the cloth desired determines the total number of threads that have to be laid one next to the other and controlled in this parallel position throughout the weaving operation. During warping each thread must be kept separate and not overlay an adjacent thread, as this would cause streaks in the woven fabric. The warps can be made in any desired length to more than 2,000 yd. for piece-dyed fabrics. The number of threads per inch will range from 90 to more than 400, depending on the construction or weave of the fabric, in widths ranging from very narrow for ribbons to 50 in. for broad silks.

The entering operation is the process of threading each warp end through the eye of a heddle. In modern mills, heddles are made of flat stainless steel, 11 to 13 in. long and $\frac{1}{16}$ to $\frac{1}{8}$ in. wide, with the eye in the centre of their length. The heddles are distributed on bands of steel held top and bottom in frames called shafts, at least wide enough to accommodate the width of the warp. The type of weave desired determines the minimum number of shafts to be used, and the number of heddles must correspond to the number of weaving ends in the warp. Since each weaving end must have a heddle to control it, a warp of 15,000 ends, if running each end single, must have 15,000 heddles, and, if this is to be a satin made on five shafts, the 15,000 heddles would be distributed equally on the five shafts, with 3,000 heddles per shaft. After the warp ends are entered into the heddles, they must be controlled further to achieve the desired density of the fabric. This is accomplished by the use of a reed. The reed is made of flat steel wire, $\frac{1}{16}$ to $\frac{1}{8}$ in. deep and 4 to $4\frac{1}{2}$ in. high, soldered into strips of steel top and bottom to hold them in place equidistant. Each space between two adjacent wires is referred to as a dent. If the construction calls for 300 ends per inch in the warp and they are distributed on five shafts, five ends would be threaded in a dent of a 60 count reed (that is a reed with 60 dents per inch), thus fixing the thread count per inch in the fabric. The shafts, heddles and reed when grouped together are termed harness because they control the threads in the warp during the weaving operation.

The entering operation just described is employed when a new type or design of fabric is to be produced. However, when a warp has been woven out and the same or related fabric is to be continued, the threads in a new warp are twisted or tied onto the previous warp in an operation called twisting. Originally, this operation was accomplished by hand, each end of the previous warp being twisted onto an end of the new warp. It required great skill and was very time consuming; an excellent operator could average only about 700 to 1,000 twists per hour. The operation now is accomplished by a machine called a twister or knotter, which will twist or tie individual knots at a rate of 17,000 per hour.

The quilling operation places the filling yarn on a suitable bobbin or quill. Modern quilling machines are high speed, sensitive, and almost fully automatic. The quilling spindle is started and an empty quill is automatically positioned, rotating at more than 12,000 rpm. When the quill is full, the spindle automatically stops,

ejects the full quill, returns to the starting position and positions a new empty quill. The full quills are automatically packaged, ready to be transported to the weaving operation for insertion in the shuttle in the loom. All of these operations are accomplished with very little tension, so as not to stretch or damage the fine silk threads.

Silk looms operate on the same principles as other textile looms. There are plain looms running one shuttle and box looms with two to seven shuttles. The up and down motion of the harness shafts are controlled in the plain and box looms by means of rotating cams that raise and lower each shaft in a restricted, fixed pattern, or by a device called a dobby head, which has greater flexibility in the control of the up and down movement of the harness shafts. In general, the plain looms weave the flat fabrics such as taffetas and linings; the box looms make the crepes and novelties. Jacquard weaving, using dyed yarns, produces elaborate, multi-coloured patterns in such fabrics as tapestry, brocade, brocatelle, damask, and figured dress goods (*see* also WEAVING).

All parts of the silk loom are balanced carefully to minimize vibration and give smoothness to the weaving and control of the fine silk threads. Precision that would be relatively unimportant in weaving other fibres has to be closely maintained in silk weaving.

Silk woven from the thread in its natural state is referred to as raw goods or greige goods. Because of the sericin in silk, the fabric has a lustreless, stiff, and harsh appearance that would be unacceptable for most practical uses. One exception is bolting cloth, a unique type of silk fabric used primarily by millers in sifting fine flour and also as a filter for women's powder compacts. Another exception is stencil cloth, used for screen printing and in the preparation of printed circuits in the electronics industry. Bolting cloth originally was made on hand looms in the cellars of mountain homes in the Sankt Gallen and Appenzell sections of Switzerland, where the humid air helped to overcome the static electricity produced during the weaving operation. Although some of the finer grades are still hand loomed, after 1940 most bolting cloth was manufactured on power looms.

Knitted Silk.—There are two types of warp knitted silks, tricot and milanese. Tricot is characterized by fine vertical wales on the face and crosswise ribs on the back. Its construction permits the making of designs such as stripes. Milanese is a fabric in which the threads are interknitted at every course in which the threads run diagonally. A fine rib on the face and a faint diagonal or diamond effect on the back are characteristic. These fabrics are run resistant and are used for women's gloves, lingerie, etc., and, after printing, for women's lightweight, crease-resisting dresses. In women's hosiery, silk has been displaced almost entirely by nylon.

5. Degumming, Dyeing, Printing, and Finishing.—Silk fabrics woven as raw goods must be degummed or scoured before they are dyed and finished. These fabrics are termed piece-dyed to differentiate them from the yarn-dyed, which are woven with yarns dyed in the thread before weaving. The degumming process is done as part of the dyeing and finishing operation.

Silk is usually boiled-off in a solution of 30% of its own weight of neutral soap dissolved in sufficient water to give a 1% solution. If degummed in skeins, the raw silk is immersed in this solution which is maintained at a temperature just below the boiling point, the skeins being turned to expose all parts equally to the solvent action of the hot solution. If woven in the gum, the fabrics are degummed in the same type of solution. After one hour the silk usually is given a second bath with half the quantity of soap. The moisture is removed in a centrifuge.

Care must be exercised not to overdo the scouring. Perfect scouring reduces the weight approximately 20% to 27% and renders the silk a brilliant pearly white with a delicate, soft, flossy texture, since the filaments that were agglutinated are separated from each other and reflect light in a beautiful, deep lustre. Silks to be finished white are bleached at this point, usually with hydrogen peroxide.

Silk has an excellent affinity for dyestuffs and finishing materials, and the handling of the fibre either as yarn or fabric has been the pride of dyers throughout the ages. The finishing of silk fabrics to give them smoothness, lustre, stiffness, or rustle also has been the subject of constant experimentation by master dyers. Although formulas have been published for dyeing and finishing preparations, every dyer treasures his own method of handling silk, and pride of individual artisanship continues.

Silk, for centuries, has been treated with salts of tin and lead to increase its weight and give pure silk more body and close texture. This weighting of pure silk also reduced its cost. Practically all U.S. silk fabrics are unweighted pure silk, pure dyed, but the practice of weighting is carried on to a small extent in Europe and Japan within strict limits laid down by the International Silk Association. Governmental bodies in the United States and some other countries require that, where any weighting is present in silk fabrics, the percentage of weighting to the weight of the silk fibre content in the finished fabric must be stated on the label.

Until shortly after World War I, almost all silk was printed by the hand-block process. This is a highly skilled operation and the craft has practically died out, though it is still carried on by one or two firms in England for the luxury men's wear trade.

Most printing of silk fabrics is done by the same general methods followed in other textiles. Roller printing is done by engraved copper rollers, with a separate roller for each colour in the design. Designs run from one to ten colours and can be printed by application or discharge. In the first, the design is applied to the cloth; in the second, the design and colours are chemically developed after printing.

Screen printing, a more expensive process, gives a hand-printed effect and is preferred especially for silk; more brilliant colour effects are achieved, and there is wider latitude in the type of design. A separate screen is used for each colour, and the number of colours that can be employed is almost unlimited. Screen printing is slower than roller printing and frequently is used where a smaller quantity of a given design is wanted (*see* also TEXTILE PRINTING).

Finishing gives the dyed and printed silk smoothness, deep lustre, and suppleness, and provides protection against certain characteristics of wear such as creasing, perspiration stains, and water-spotting. In the finishing operation, minute quantities of starches, sulfonated oils, glycerin, resin, and various organic chemical compounds are used individually or in combination as softeners and penetrants to achieve the desired effects of drape and feel. Fabrics must be finished wrinkle free and to a uniform width. The natural strength and elasticity of silk provides ample opportunity for manipulation in processing.

6. Silk Cloth.—Some of the fabrics long identified in the public mind with silk are taffeta, satin, chiffon, crepe, crepe de Chine, shantung, surah, organza, and faille.

Taffeta is made either piece-dyed or yarn-dyed and is considered a medium-weight fabric. It is opaque and has a semibright lustre, with a smooth, flat, firm, crisp texture. Garments made of this fabric usually have a semibouffant silhouette.

Satin is made either piece-dyed or yarn-dyed and may be either a light- or heavyweight fabric. It is opaque, with a bright lustre on the face side and duller on the back, with a slick, smooth touch and soft or firm texture, as desired.

Chiffon is a piece-dyed, lightweight, sheer fabric. It is translucent, with a semidull lustre and a sheer, gauzelike, grainy texture, with a soft drape. It is printed also.

Crepe de Chine is a lightweight, piece-dyed fabric. It is opaque, with a semidull lustre and a smooth, slightly crinkly texture, with a soft drape. It is printed also.

Shantung most frequently is piece-dyed and can be either a very light- or heavyweight fabric. It is opaque, with a semidull lustre, being woven with doupioni silk filling, or, more usually, with tussah silk. It has an uneven, soft texture, with random thick and thin portions in the yarn called slubs. It is an extremely popular fabric, much imitated in man-made fibres.

Surah is made either piece-dyed or yarn-dyed. In the U.S. this term is synonomous with tie silk. In Britain tie silk indicates Jacquard woven tie cloths; printed surah is known as foulard in the men's trade. It can be either a light- or heavyweight fabric.

It is opaque, with a semibright lustre, firm drape, and a smooth texture, with a clearly defined diagonal weave. This is the base fabric for much printed silk.

Organza is a lightweight, sheer fabric, which is yarn-dyed in the gum. It is almost transparent, with a dull lustre and a meshlike, flat, firm, starchy, stiff texture, and in printed form is used a great deal by the haute couture.

Faille is usually yarn-dyed and a medium- to heavyweight fabric. It is opaque, with a semibright lustre and has a thick, smooth, firm texture, with a clearly defined rib running crosswise from selvage to selvage.

These and other silk fabrics long have been valued for their aesthetic appeal, but silk is not merely a fashion fabric; it also has many utilitarian uses. Until 1942 it was the major fabric used for parachutes, a usage preserved in the expression "hit the silk," meaning to parachute from an airplane. Silk remains the standard of excellence by which nonsilk fabrics and, indeed, many other items are judged. "Smooth as silk" and "the silken touch" have not without reason become everyday descriptive phrases.

SILK SCREEN PRINTING. The silk screen printing process is the modern commercial form of stencil printing. Since the screen may be made from wire gauze, cotton fabrics and other materials as well as from silk bolting cloth, the process is generally called screen printing by commercial printers. Artists use specialized techniques and call their method serigraphy to distinguish it from the commercial variety.

Principles and Uses.—In screen printing the design is painted on, or affixed to, a sheet of silk bolting cloth or other screen material that is stretched tightly over a wooden or metal frame. The frame, which is hinged to a base or table, is dropped to make contact with the paper or other material to be printed. Ink that resembles paint is poured on one end of the screen and is forced through the open mesh by the scraping action of a squeegee, a thin but firm strip of rubber set in a wooden form that serves as a handle. The open areas in the screen allow the ink to pass through, but the solid areas are impermeable. The design thus is transmitted in terms of open and blocked areas of the screen. The screen is then swung back, the paper is removed to dry and another sheet is positioned for another impression. Each colour requires a separate screen but, since one colour can be printed in register over another, any number of colours can be used in a single design. A reducing varnish is mixed with the colours to permit easy passage through the mesh, and a transparent base (a Vaselinelike substance) is mixed in to achieve transparent effects.

Compared with other printing processes, screen stencil printing is slow, since it usually is employed as a hand method, but it has the advantage of requiring relatively cheap equipment and comparatively little preliminary work. It is economical especially for runs of up to 3,500 impressions; therefore, it is used widely for show cards, posters, signs, charts and decalcomanias. It permits printing on almost any surface, including paper, cloth, glass, wood, plastic, rubber, metal, linoleum and oilcloth. Areas of relatively great size can be stenciled; *e.g.*, frames 50 × 60 in. are used frequently in textile printing. (*See* Textile Printing: *Modern Industrial Processes: Stencil and Screen Printing*.)

As the objects to be decorated need not be limited in thickness, nor even be flat, the screen method is used widely for printing on such objects as toys, novelties, bottles and machinery. The process is not suitable, however, for work where fine details and delicate gradations of tone are needed, as in the reproduction of photographs and in colour printing. While such work can be done, the results are comparatively coarse.

Mechanical methods have been applied to screen printing; automatic presses with speeds up to 1,800 impressions per hour are in general use.

Developments.—The stencil method is very old. By A.D. 500 it was used commonly in China and Japan. A Japanese screen with stenciled decorations, dated about A.D. 700, is in the collection of the Fogg museum at Harvard university. A highly developed method was used in Japan from the late 17th century to recent times. The designs, often very intricate, were cut in separate pieces of parchment. These were tied or glued in place by numerous crossing strands of silk or of human hair.

The first consistent use of stencils in Europe dates from the late 15th century. Playing cards and religious subjects printed from wood blocks were coloured by stencil. In the late 17th century, wallpaper was produced in France by the same method, notably by Jean Papillon. Stenciling was widely used in the United States after 1800 for decorating walls, floors, furniture, clocks and trays. The painting of patterns on velvet with stencils became a genteel accomplishment for young ladies.

The use of silk screens is a 20th-century development. Samuel Simon of Manchester, Eng., received a patent for this process in 1907, after which the method was adopted slowly until, in the late 1920s, it came into limited use as a commercial printing method. After that time it grew rapidly into a large industry.

Serigraphy is used widely by artists for creating original designs in colour. Although a few prints were produced in the early 1930s, the process first attracted general attention in 1938 when Anthony Velonis organized a group of artists on the New York city Work Projects administration (WPA) art project. The new medium was named serigraphy by the art historian Carl Zigrosser.

Preparation of Screens.—Silk screen stencils can be prepared by a variety of methods. Photography is employed increasingly, but a number of hand techniques are still in use.

Aside from such primitive methods as painting with shellac and stopping out with pasted paper, the oldest and simplest is the cutting of a film stencil with a knife. In this process a thin prepared film with a translucent backing (*e.g.*, paper acetate, vinyl or Mylar) is placed over the design to be reproduced. The cutter, using a special knife, follows the outlines of the design, cutting through the film but not through the backing. The cut film is removed and the remaining film is laid face-up on a flat support. The underside of the screen is laid on the film, which is made to adhere by applying a solvent. The screen is then turned and the backing is stripped away.

In serigraphy the design is drawn on the silk with lithographic tusche, a viscid, greasy ink, and with lithographic crayon for delicate shadings. The screen is coated with a water-soluble glue solution and, after the screen dries, the tusche image is washed out with an organic solvent such as kerosene. This lays the screen bare in the design areas. Since the original colour sketch is visible through the screen, the artist can prepare a separate screen for each colour and superimpose one over another.

Many techniques are used in photographic silk screen work. The most versatile involves the use of a special carbon tissue composed of a paper base coated with a pigmented (usually red) gelatin solution. This tissue is immersed in a solution of light-sensitive ammonium or potassium dichromate (bichromate), after which a squeegee is used to press the tissue onto a thin sheet of clear plastic. A photographic positive is placed over the plastic and exposed to an arc light. The gelatin thus is hardened under the transparent areas of the positive, while the areas under the design remain soft and are washed away with warm water. The paper backing of the carbon tissue then is stripped off, the image is affixed to a screen and the temporary plastic support is removed. The design thus is open to the passage of ink, while the hardened gelatin areas act as stop outs.

SILL, ANNA PECK (1816–1889), U.S. educator, a pioneer in women's education in the United States who sought to bring the education of girls to the level of that for men, was born Aug. 9, 1816, at Burlington, N.Y. After attending the district school, she began to teach at a school near Albion, N.Y., and in 1837 entered Miss Phipps' Union seminary, where she shortly became a member of the faculty. There she remained until 1843, when she established a seminary for girls at Warsaw, N.Y.

After three years Miss Sill abandoned this project and went to teach at Cary Collegiate institute, Oakfield, N.Y. She was invited to Rockford, Ill., in 1849 to open a girls' seminary and was made principal of the school (Rockford Female seminary) in 1852. Thereafter she spent much of her time raising funds for the young institution. It expanded gradually until in 1882 it began to confer collegiate degrees. The name was changed to Rockford college in 1892.

Miss Sill had retired in 1884, but she remained with the institution as principal emerita and taught occasional classes. She died in Rockford on June 18, 1889.

SILL. In geology, a tabular body of igneous rock formed by intrusion of magma (molten rock) along a structural break (bedding or foliation) in the earth. The tabular form and parallelism with surrounding structure are the diagnostic features. To many geologists there is another essential; injection must have occurred along relatively flat-lying breaks. The magma, therefore, displaced the adjacent rock vertically by lifting the roof. This mechanism is quite different from that involved in the formation of steep intrusive sheets (most dikes). In the latter, magma entered passively as the walls of the steep fractures were spread apart by horizontal movements.

It is believed that, as the injected magma comes into contact with the cooler adjacent rock, it becomes chilled and rapidly solidified to form a thin, dense selvage or layer along the sill roof and floor. Somewhat slower cooling of the more internal portions of the sill results in coarser textures. Margins of many sills show a streaked and banded appearance, believed to have been produced by liquid flow along the smooth sill roof and floor. Large crystals commonly show parallel arrangement of their long dimensions near sill boundaries. These are believed to have formed early and to have been turned into the lines and layers of flow parallel to sill contacts.

Some sills, after congealation, have been split open and injected by fresh magma. Such bodies are called multiple sills if the successive injections were of one kind of magma, and composite sills if different kinds of magma were involved.

Sills may range up to several thousand feet in thickness and may extend across country for hundreds of miles. They are commonly associated with dikes and larger intrusive bodies (*see* Batholith; Laccolith; Geology). Most described sills are composed of diabase or dolerite and closely related rocks. Granitic, rhyolitic, dioritic, and andesitic sills are locally abundant; and the rocks comprising them commonly belong to the class known as porphyries (*see* Porphyry).

Some thick sills, such as the Palisades sill in New Jersey, furnish striking evidence that an essentially homogenous magma became differentiated during consolidation and yielded a diverse, layered series of rocks. In general, such sills show a dense chill zone at the top and bottom; and heavy rocks, near the base, grade upward to somewhat lighter rocks near the top. It seems clear that early developed heavy crystals (olivine and pyroxene) settled in the slowly congealing magma, whereas lighter minerals (feldspar) may have remained more or less stationary or possibly were buoyed upward.

The rocks immediately in contact with sills commonly appear to have been profoundly changed. This phenomenon, known as contact metamorphism, is believed to have been brought about largely by the heat of the intrusive magma. In the case of large sills, the metamorphic zone may extend a few hundred feet from the intrusive margin. Sedimentary rocks may show a baked or indurated and bleached appearance in contact with a sill roof or floor. Shale, for example, has commonly been reconstituted to a tough, brittle rock called hornfels, in which many new minerals (cordierite, feldspar, garnet, pyroxene, etc.) have formed. Blocks and fragments of the adjacent rock, accidentally caught up in the intrusive mass, may also show these metamorphic effects (*see* also Metamorphism).

See M. P. Billings, *Structural Geology* (1954); R. A. Daly, *Igneous Rocks and the Depths of the Earth* (1933). (C. A. Cn.)

SILLANPÄÄ, FRANS EEMIL (1888–1964), the first Finnish writer to win the Nobel Prize for Literature (1939). The son of a peasant farmer, he was born at Hämeenkyrö, in southwest Finland, on Sept. 16, 1888. At Helsinki University, where he studied natural science, he was influenced by the monistic philosophy of Wilhelm Ostwald (*q.v.*). In 1913 he broke off his studies, returned to the country, married, and began to write. His first short stories were published in journals in 1915. From 1924 to 1927 he worked for a publishing company in Porvoo. A personal crisis was followed by a new creative period in the early 1930s, when several of his best works were written. He died at Helsinki on June 3, 1964.

Sillanpää's first novel, *Elämä ja aurinko* (1916; "Life and Sun"), the story of a young man who returns home in midsummer and falls in love, is characteristic both in title and subject. In all his work, life itself is the dominant force. People are seen as essentially part of nature, which is not merely a lyrical background. Instinct, through which life's hidden purpose is revealed, rules human actions.

Shocked by the Finnish civil war of 1918, Sillanpää wrote his most substantial novel, *Hurskas kurjuus* (1919; *Meek Heritage*, 1938), describing how a humble cottager becomes involved with the Red guards without clearly realizing the ideological implications. The novelette *Hiltu ja Ragnar* (1923) is the tragic love story of a city boy (Ragnar) and a country servant-girl (Hiltu). After several collections of short stories in the late 1920s, Sillanpää published his best-known, though not his most perfect work, *Nuorena nukkunut* (1931; *Fallen Asleep While Young* [U.S. title *The Maid Silja*] 1933). This tells poetically the story of an old peasant family. In *Miehen tie* (1932), describing a young farmer's growth to maturity, realistic and lyric elements are blended. *Ihmiset suviyössä* (1934; "People in a Summer's Night"), is stylistically his most finished and poetic novel. His reminiscences, *Poika eli elämäänsä* (1953) and *Päivä korkeimmillaan* (1956), throw new light on his personality as a writer.

See studies of Sillanpää by T. Vaaskivi (1937), R. Koskimies (1948), and A. Laurila (1958). (K. L. K. L.)

SILLIMAN, BENJAMIN (1779–1864), U.S. chemist and geologist, best known as the founder (1818) and, until 1838, sole editor of the *American Journal of Science and Arts*, popularly called *Silliman's Journal*. He was born at North Stratford (now Trumbull), Conn., on Aug. 8, 1779. The son of a Revolutionary War general, he graduated from Yale College in 1796, becoming a tutor in 1799 and professor of chemistry and natural history in 1802. He taught chemistry, mineralogy, geology, and pharmacy, and aided greatly in expanding Yale's educational resources, especially the mineralogical collections, the Sheffield Scientific School, the Trumbull Gallery, and the Medical School. His clear, interesting expositions and skilful illustrative experiments made him a popular scientific lecturer.

After visiting Europe in 1805, Silliman wrote *A Journal of Travels in England, Holland and Scotland* (1810), and a similar publication resulted from another European tour in 1851. His other books included *Elements of Chemistry* (1830), and editions of William Henry's *Chemistry* (1808) and Robert Bakewell's *Geology* (1827). He retired in 1853 as professor emeritus, and died at New Haven on Nov. 24, 1864. The mineral sillimanite was named for him.

Benjamin Silliman (1816–1885), his son, achieved distinction in applied chemistry and, like his father, as a popular lecturer. Born at New Haven on Dec. 4, 1816, he graduated from Yale in 1837, and assisted his father in setting up a chemical laboratory

(1842) out of which later grew the Sheffield Scientific School. He taught medical chemistry and toxicology at the University of Louisville, Ky., from 1849 to 1854. His lectures on agricultural chemistry at New Orleans in 1845–46 are believed to have been the first such course in the United States. In 1854 he returned to Yale to succeed his father in the chair of chemistry. He relinquished most duties of this professorship in 1870, but continued lecturing until his death, at New Haven, on Jan. 14, 1885.

The younger Silliman prepared numerous reports on mines and on technical manufacturing processes, and conducted fundamental research on meteorites, photography, gases, etc. His now famous "Silliman report," (April 1855) gave impetus to plans for drilling the first producing oil well, near Titusville, Pa., in 1859. The document was a 20-page report of Silliman's analysis of a sticky substance which had been found in Pennsylvania and sent to him for examination. The substance was petroleum, and he indicated its exceptional suitability for lubricating, lighting, and other purposes and emphasized its potentially great economic possibilities. Few researchers have so profoundly influenced industrial development and human lives. (*See* CHEMICAL INDUSTRY: *Petrochemical Industry.*)

In 1846 Silliman published *First Principles of Chemistry*, and in 1858 *First Principles of Physics or Natural Philosophy*, both widely used. In 1853 he edited *The World of Science, Art and Industry*, and in 1854 *The Progress of Science and Mechanism*. For the Centennial of Chemistry in 1874 he presented a notable address, "American Contributions to Chemistry." He assisted his father with the *American Journal of Science* from 1838 to 1845, and was its co-editor in chief until his death. (F. M. FL.)

SILLIMANITE, an aluminum silicate mineral that, like the closely related aluminum silicates andalusite and kyanite (*q.v.*), may be used to form mullite, an important refractory material (*see* also MULLITE). It crystallizes in the orthorhombic system and has the composition $Al_2O_3.SiO_2$. It occurs in metamorphic rocks as long slender crystals and as rosettes. The hardness range is from 6 to 7 and specific gravity from 3.23 to 3.24. Its colour ranges from brown to gray to olive-green. In the laboratory it may be synthesized over a limited range of temperatures and pressures and is presumably so formed in nature. At pressures under approximately 3,000 atm., in the temperature region of 600°–900° C., the stable phase of essentially the same composition is the mineral mullite. Sillimanite occurs at pressures from 3,000 to 12,000 atm. Above these pressures the mineral kyanite appears. At temperatures below approximately 600° C. the polymorph of sillimanite, andalusite, appears. It is an important geological mineral and serves as an indicator both of temperature and pressure of environment in which rocks containing it were formed. It is present in metamorphosed kaolin-rich sediments. It was named after Benjamin Silliman (*q.v.*). (G. C. KY.)

SILO: *see* ENSILAGE.

SILONE, IGNAZIO (pseudonym of SECONDO TRANQUILLI) (1900–), Italian author whose novels reflect his belief in the need for social reform, was born at Pescina dei Marsi, Abruzzi, on May 1, 1900. One of the founders of the Italian Communist party, he left the party in 1930 while in exile in Switzerland. Returning to Italy in 1944, he continued to influence Italian socialism, although without holding any important political office.

Silone's first novel, *Fontamara* (1930; Eng. trans., 1934), is a poignant description of poverty and Fascist oppression in an Abruzzi village. Its peasant hero, who struggles for freedom but dies in prison, believes that political and social regeneration will be accomplished by a Communist revolution. The hero of *Pane e vino* (1937; Eng. trans., *Bread and Wine*, 1937) and *Il Seme sotto la Neve* (1940; Eng. trans., *The Seed Beneath the Snow*, 1943) has turned from Communism to a Christian belief in universal brotherhood.

In *Una Manciata di More* (1952; Eng. trans., *A Handful of Blackberries*, 1954) Silone denounces Communism though still urging social reform and the development of the south of Italy, which is also the subject of *Il segreto di Luca* (1956).

See bibliography in *Fiera letteraria* (Aug. 14, 1955); an essay by Edmund Wilson in the *New Yorker* (Sept. 8, 1945). (F. DI.)

SILURIAN SYSTEM. This article is divided into several broad sections and subsections dealing with the Silurian system and period of geologic time. In addition to the cross references to related material given under the various headings of this article, for general background information *see* GEOLOGY: *Historical Geology*; PALEOBOTANY; PALEONTOLOGY.

For additional information on the forms of life referred to *see* separate articles on these forms, as ECHINODERMATA; FISH; etc. *See* also references under "Silurian System" in the Index.

Following are the main divisions of this article:

I. The Silurian System and Period
  1. Physical Events and Features
  2. Climate and General Ecology
  3. Facies, Biogeography and Migration Routes
II. Silurian Life
  1. Characteristics and Evolution
  2. Invertebrates and Associated Fossils
  3. Fishes, Land Plants and Associated Fossils
III. Regional Summary
  1. Great Britain
  2. European Continent
  3. U.S.S.R.
  4. Asia
  5. Australia
  6. South America
  7. North Africa
  8. North America

I. THE SILURIAN SYSTEM AND PERIOD

Rocks of the Silurian system are those that were formed during the Silurian period, which is roughly the interval from 405,000,000 to 435,000,000 years ago, a middle division of the Paleozoic era (*q.v.*), as indicated on the accompanying geologic time chart. Many European geologists outside of England and the U.S.S.R. also include under the term Silurian the older rocks and the earlier time more generally called Ordovician. To them the Silurian as

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	Began (Millions of Years Ago)
	CENOZOIC ERA		
Quaternary	Recent (last 11,000 years)		
	Pleistocene	Early man	2+
Tertiary	Pliocene	Large carnivores	10
	Miocene	Whales, apes, grazing forms	27
	Oligocene	Large browsing mammals	38
	Eocene	Rise of flowering plants	55
	Paleocene	First placental mammals	65–70
	MESOZOIC ERA		
Cretaceous		Extinction of dinosaurs	130
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	180
Triassic		Appearance of dinosaurs	225
	PALEOZOIC ERA		
Permian		Reptiles developed, conifers abundant	260
Carboniferous			
Upper (Pennsylvanian)		First reptiles, coal forests	300
Lower (Mississippian)		Sharks abundant	340
Devonian		Amphibians appeared, fishes abundant	405
Silurian		Earliest land plants and animals	435
Ordovician		First primitive fishes	480
Cambrian		Marine invertebrates	550–570
	PRECAMBRIAN TIME		
		Few fossils	more than 3,490

here defined is Upper (or Late) Silurian or Gotlandian.

Rocks of the Silurian system have yielded about 10% of U.S. iron, 20% of its salt and a little oil and gas. They also serve, especially where mainly limestone and dolomite, as host for many metallic mineral deposits, including important gold and tin ores in eastern Australia. And they are exploited industrially for cement, agricultural lime and building stone.

Silurian volcanoes dumped thousands of cubic miles of debris into linear subsiding zones and basins in eastern Australia and other regions, announcing related mountain building of this age. Contemporaneous deposits provide the earliest reasonably varied occurrences of fishes and land plants. Although both originated tens of millions of years before, neither is widely recorded until

Devonian time. An aberrant vertebrate relative, *Monograptus*, the last surviving bladelike graptolite (*q.v.*), burst into a flowering of short-lived species whose flexible external skeletons are used to divide the Silurian marine deposits of the world into time-equivalent zones. Archaic reef-building corals and the brachiopods advanced less speedily but over broader fronts. The evidence of all these creatures, and the sediments, is interpreted to signify mild climates; not markedly zoned latitudinally, but with local, long-lasting, Late Silurian arid regions.

The responses of Silurian rocks to local conditions of erosion and weathering account for many of the world's distinctive landscapes. Undercutting of weak sedimentary layers beneath massive Middle Silurian dolomites at the outlet of Lake Erie created and maintains Niagara falls. The picturesque glade country of Tennessee consists of isolated grassy areas on infertile shales surrounded by wooded areas on more calcareous shales or limestones of Middle Silurian Age. Beautiful Wenlock Edge in Shropshire is an east-dipping Middle Silurian limestone ridge, and much of Wales and the Lake district of England is underlain by Silurian rocks. The Swedish island of Gotland is the type site of the Gotlandian; picturesque Visby, its capital and ancient Hanseatic harbour, is built around a Silurian reef limestone.

Rocks are identified as Silurian (or a specific part of it) from comparison of their contained fossils with those of the type marine sequence in south Wales and Shropshire, or on relationship to or correlation with other rocks so dated. By definition, therefore, the Silurian includes all deposits formed during the same time as those in the type sequence, regardless of origin, location, or local relationships. The principal Silurian subdivisions for selected regions are outlined in the accompanying correlation table, emphasizing marine sequences as the basic local standards.

The Silurian is an enduring monument to British persistence. The Roman emperor Tiberius Claudius vowed (*c.* A.D. 43) to exterminate even the name of the warlike Silures of areas now in the Welsh borderland for their stubborn resistance under Caractacus (Caradoc). Beaten and dispersed by Julius Frontinus for Vespasian (A.D. 78), they were, in fact, almost forgotten until 1835, when Scotsman Sir Roderick Impey Murchison (*q.v.*), an old soldier himself, delighted in naming his new rock system for them. In his epochal *The Silurian System* (1839), Murchison reflects how:

> In ancient days
> The Roman legions and great Cesar found
> Our fathers no mean foes, and Cressy plains
> And Agincourt, deep tinged with blood, confess
> What the Silures' vigour withstood
> Could do in rigid fight.

He and his British successors have done a job worthy of their ancestors in unraveling the complicated rock succession of the type Silurian, subdividing it and establishing its graptolitic and shelly faunas as independent world-wide standards for correlation. In most of the rest of the world, however, the Silurian is one of the most neglected and thus most poorly known sequences—ironic contrast to the wide attention given to the lower part of Murchison's original Silurian, the Ordovician, which was not split off as an independent system until 1879.

1. Physical Events and Features.—Mountain-building deformation older than the oldest local Silurian deposits is indicated by Silurian overlap across folded Ordovician rocks in the Acadian region of east central North America (Taconic folding or orogeny) and eastern Australia (Benambean orogeny). Similar relationships indicate later deformation between Silurian and overlying Devonian in Australia (Bowning orogeny), in northwestern Europe (Caledonian orogeny) and apparently in the western U.S. Thus it is frequently said that the Silurian began and ended with important, if local, compressive movements of the earth's crust. Strong evidences of volcanism throughout the Silurian of eastern Australia, the Pacific border of North America and the Acadian region, however, and the thick sequences of coarse detrital sediments in Australia, south Scotland and the eastern Appalachian trough seem to imply continued crustal instability in the borderlands. As a consequence of such events, some seaways that were well defined during Ordovician time were strongly modified or abandoned in the Silurian, and new directions of marine invasion were found.

2. Climate and General Ecology.—Widespread reef formation by Silurian corals and stromatoporoids (hydrozoan relatives) couples with the evidence for high calcium metabolism furnished by laterally equivalent limestones and dolomites to imply extensive warm shallow seas in present continental areas and little latitudinal or seasonal temperature variation. Interference of mountainous tracts with prevailing winds, or other special meteorologic circumstances, created local arid conditions in the middle latitudes such as those under which the Silurian salt and gypsum deposits of New York state and the Michigan basin originated. If deposits which some interpret as glacial in southeastern Alaska, British Columbia and northern Norway prove to be both glacial and Silurian they would suggest mountains high enough to support valley glaciers.

Principal ecologic variations were presumably connected with physical and chemical changes due to increasing depth at sea or altitude on land, or special geographic configuration.

3. Facies, Biogeography and Migration Routes.—As those of all other geologic ages, Silurian rocks formed under differing local physical or chemical conditions, or with different sources of supply and biologic migration routes, take on a characteristic stamp, or facies, which may tell a great deal about their origin and ecology. Facies variations of rocks and accompanying fossil assemblages may be lateral (in space), vertical (in time) or both. Similar sedimentary facies that do not differ drastically in age, and some that do, are likely to contain similar fossils; and different facies of the same age ordinarily contain different assemblages of fossils. (*See* also FOSSIL.)

The stratigraphic correlation of unusual facies is worked out from field relations to deposits of known age, or is based on ubiquitous fossils of restricted time span. Species of graptolites, so characteristic of Silurian as well as Ordovician beds, have proved especially useful in indicating the probable contemporaneity of contrasting sedimentary facies. They are, in fact, such generally excellent index fossils, that they are logically interpreted as animals which actually floated at the surface of the water all or much of their lives instead of living somewhere below the surface like most planktonic species or floating only temporarily like the larval stages of so many aquatic organisms. This would explain their being buried, not only with the open-sea sediments of their normal living environment, but also in many different shallow water deposits, together with bottom-living shelly fossils. In eastern Australia, for example, species of *Monograptus* establish the Silurian age and particular stratigraphic level of the important early land plant *Baragwanathia* and associated paleobotanical remains.

Classification of Silurian biotal facies (faunas and floras) shows that they follow sedimentary facies that appear to be related to distance from land, depth of water and nature and amount of detritus brought to the sedimentary site. The usual Silurian deposits and faunas (plants are not numerically important) are divisible into three principal facies of marine sediments: (1) graptolitic shale and flaggy sandstone; (2) detrital limestone and calcareous shale with shelly faunas; (3) carbonate rocks (limestone and dolomite) with mainly coral and stromatoporoid faunas. To these three primary facies types must be added evaporite sequences (salt and gypsum) with highly restricted planktonic faunas in shaly interbeds, slabby argillaceous limestones that in part seem to represent special conditions of tide-flat sedimentation, Late Silurian continental (nonmarine) deposits with plants and fishes, and the volcanic facies, which commonly grades to or alternates with graptolitic shale. The three principal facies are found in most regions with thick and extensive Silurian sections; the others represent special local conditions.

The wide dispersal of similar Silurian faunal facies implies good communication channels. Highly generalized possible connections at times of maximum marine expansion are suggested by the distribution map. The distinctive limestone and dolomite sequences of the western U.S. are very exceptional. They represent an extreme development of the carbonate facies, characterized by predominance of dolomite, with a sparse but widely distributed fauna

Correlation Table Showing General Silurian Subdivisions, Local Rock Sequences and Ranges of Representative Genera

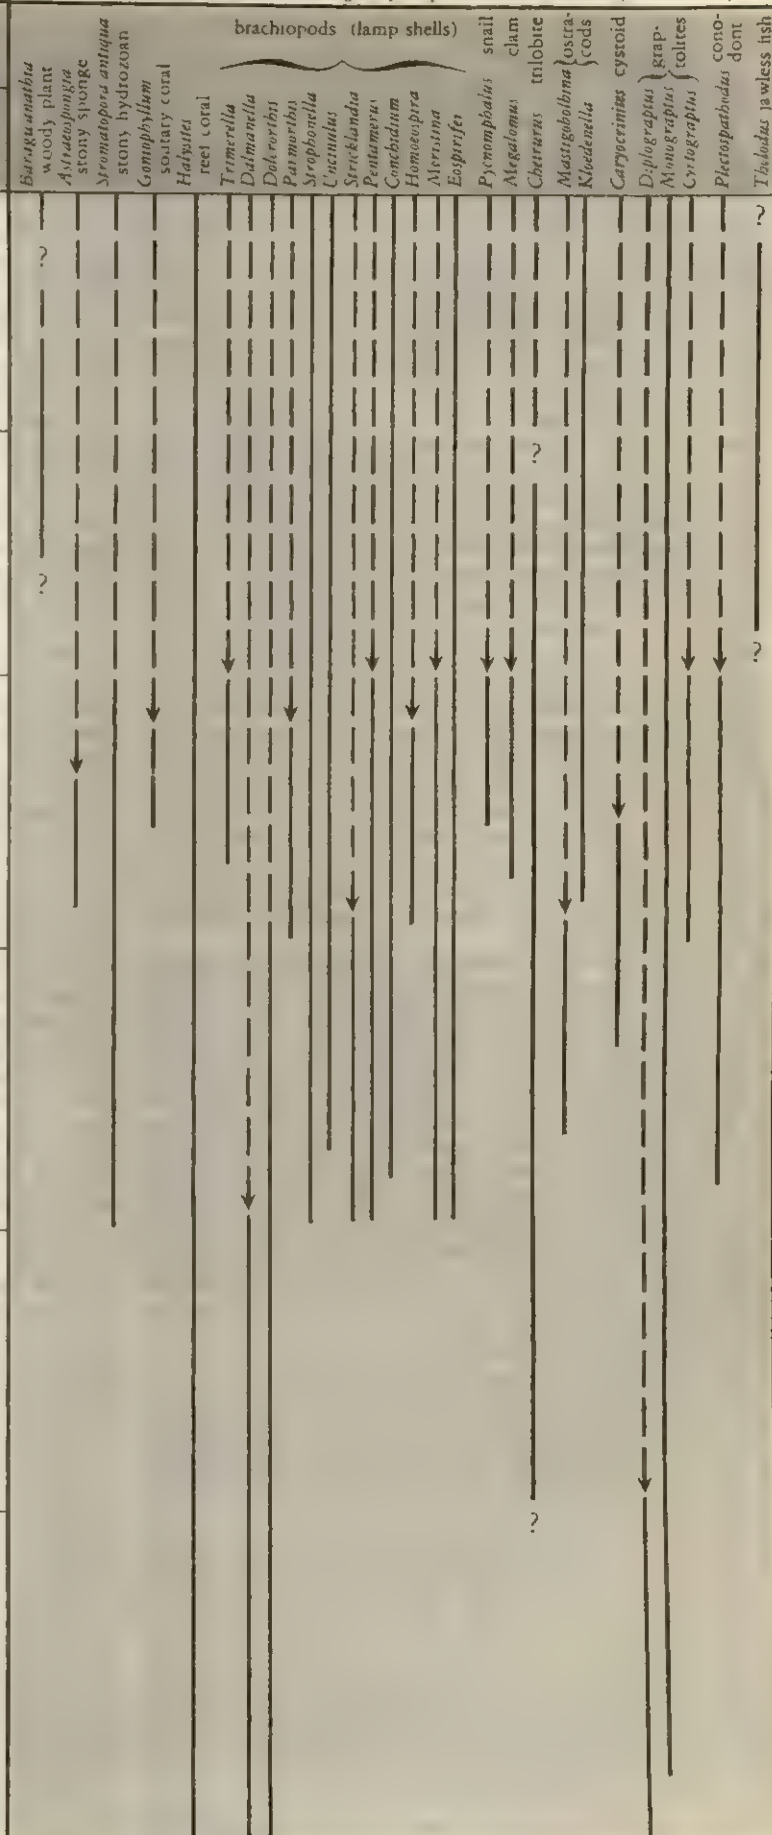
Correlation Table Showing General Silurian Subdivisions, Local Rock Sequences and Ranges of Representative Genera (Continued)

Southwest China: East and central Yunnan	East Australia: Melbourne district	East Australia: Yass district	South America	North Africa: Central Morocco
Miao-kao limestones and shales with ostracods and fish	Lower Yering sandstones, shales and conglomerates		Widely present but undivided	Shales and limestones
		Upper Hume shales, sandstones and conglomerates		Shales with *Monograptus nilssoni*
Apparently missing	Melbourne graptolitic sandstones and shales	Lower Hume shales and limestones		Shales with *Monograptus riccartonensis*
		Laidlaw tuffs and grits		
		Yass sandstones, shales and limestones		
Mien-tien shales, sandstones and limestones with *Monograptus* and *Climacograptus*	Keilor graptolitic shales, sandstones and conglomerates	Douro tufts		Shales with *Monograptus spiralis* and *turriculatus*
		Bango limestones, shales and tuffs with *Halysites*		Shales with *Monograptus regularis*
		Hawkins tuffs		Shales with *Monograptus* and *Climacograptus*



of corals and large, thick-shelled pentameroid brachiopods. Thin graptolitic shales have been found only locally. The sea in which these deposits formed may have connected with the eastern North American seaways at its south end, although proof of this is lacking.

II. SILURIAN LIFE

1. Characteristics and Evolution.—The record of Silurian invertebrate life shows essentially an elaboration of Ordovician lineages (*see* ORDOVICIAN SYSTEM). It has, however, novel and distinctive features of its own, such as expansion of the corals and echinoderms, and a general substitution of the dominant groups of brachiopods. And it differs from the Devonian record in the types of corals and brachiopods present, the continued importance of graptolites and many less striking features. These differences, of course, are due partly to accidents of preservation and vagaries of collecting and recording.

Silurian plants and fishes are the oldest preserved, except for isolated occurrences of fish fragments in the Middle and Upper Ordovician of the North American Rocky mountains and Cambrian plants reported from eastern Siberia, Estonia and north India. This distribution pattern is apparently attributable to the rarity of preserved pre-Silurian terrestrial deposits.

The characteristics and evolution of Silurian or any other fossil life are of interest not only from an aesthetic and scholarly point of view, but also because they provide the only practicable means of consistently telling fossil time. Radiogenic methods of absolute age determination do not yet suffice for general dating or correlation of the Paleozoic rocks, even though a very few apparently reliable dates are used to set, approximately, the hands of the paleontological clock in terms of years.

From the fossils also can be deduced much of the history, ecology and geography of ancient times, always in connection with the characteristics and positions of the rocks themselves. Ecologic deductions, for instance, are greatly aided by the tracks, trails and burrows made by different organisms. Indeed these are almost the only traces of life in some deposits, such as the Silurian of the eastern Appalachian trough.

2. Invertebrates and Associated Fossils.—In the Silurian, as with other fossiliferous rocks, the invertebrate and noncellular (or unicellular) organisms are the true indices of time, on the basis of which nearly all meaningful stratigraphic correlation with the standard marine sequence is founded. The form sequence of the monograptid graptolites illustrates well how such correlation may be accomplished either by relating stage of evolution to time or by the empirical knowledge of the ranges of specific morphologic types. Correlation, or paleoecological analysis, in practice, however, is usually made by analysis of the total biotal characteristics of the problem sample, considered in relation to lithology and sequence of the enclosing sediments. Ranges of selected index genera at the right side of the correlation table illustrate how Silurian fossiliferous sediments can be dated, using apparent terminal ranges of a variety of fossils.

The graptolites, despite their suggested close alliance to the vertebrates, are at best invertebrate chordates, and, in this sense, the most conspicuous and distinctive Silurian invertebrates. The monograptids are the evolutionary culmination of the simple sawblade-like forms of graptolites and appear to be exclusively Silurian—no Ordovician or Devonian report has ever been unequivocally substantiated.

Moreover, only a few species of two genera (*Diplograptus* and *Climacograptus*) of their Ordovician ancestors carried over into the Silurian, and these only into the lower part. The Silurian graptolite assemblage thus consists almost entirely of *Monograptus*, of short-lived derivative genera from it or older forms, and of occasional reticulate colonies such as persisted into the Devonian. The apparent time subdivision of Silurian rocks is based largely on short-ranged species of *Monograptus*—18 of the 26 graptolite zones in the type Silurian sequence are so characterized, and many of the same species floated around the world.

Corals and stromatoporoids are subordinate to the graptolites as Silurian time indicators but far ahead of them in range of evolutionary diversification. Compound corals particularly flourished, including the tabulates, which now reached their greatest expansion, and fasciculate tetracorals which did not attain their acme until the Devonian. Horn corals of simple types were more abundant and more complicated than Ordovician, less so than Devonian relatives. Stromatoporoids had also to await the Devonian for their climax, and no Silurian or other common Paleozoic coelenterate is anything like its modern relatives. Presumably however, they did have the same alternation of sessile and free-floating generations as typifies the living representatives of the phylum, which would account for wide distribution of identical species in favourable environments. Unlike the graptolites, which apparently could drift even after death, they are not found far from their place of life except as a result of unusual events.

Bryozoa are still about as common as they were in the Ordovician, with a slight dwindling of stony types and an increase of the more delicately ornamented twiglike cryptostomes. Locally they made small mounds at the bottom of the Silurian seas, as represented by the ball reefs of the Rochester shale in western New York state.

Among Silurian brachiopods, the globular, short-hinged and commonly large pentameroids were the most distinctive forms. Short-hinged spire-bearing brachiopods were essentially new, although there are common Ordovician forms. The wide-hinged spiriferoids began the expansion that was to flower in Devonian and Lower Carboniferous time.

The pelecypods continued to expand slowly from Ordovician beginnings, and the prosobranch gastropods became important fossils, in continuance of a long, progressive expansion to modern times. Among the cephalopods, ammonoid progenitors appeared and nautiloids dwindled. Some distinctive Ordovician groups of nautiloids were missing completely (*e.g.*, Endoceratida) and others died out during the Silurian (*e.g.*, Ascoceratida). As if to emphasize their decline, no important new nautiloid groups appeared.

Among the arthropods, trilobites continued their slow decline from a Cambrian maximum, and ostracods and merostomes both expanded slightly. Among the latter, eurypterids became much more common, while the aglaspids were missing; but xiphosurans ancestral to living *Limulus* are recorded. Ostracods are locally abundant and useful Silurian index arthropods. Trilobites, despite their general decline, showed an expansion of bizarre spiny types, perhaps as an adaptation to floating or camouflage, forced by increasing competition for the nutrient-rich bottom niches or predation. Allied developments may have caused the eurypterids to enter fresh water in later Silurian time, from which, according to one theory, they eventually chased the fishes. It is an old law of life that each time new or better offensive or competitive equipment or tactics are evolved compensation is made, or the hunted or competitive inferior perishes or takes exile.

Crinoids were the most successful Silurian echinoderms, enjoying their greatest recorded expansion of numbers and kinds. Unlike their commoner living relatives, these lilies of the sea were stalked forms; if they were equally colourful their colonies were the showy marine gardens of Silurian time. Cystoids were also common, and, although much more primitive, were similar in living habits and appearance to the crinoids. Other echinoderms were not important.

Noncellular invertebrates, or the Protista (Protophyta and Protozoa), are abundant in some Silurian deposits. Chitinous and agglutinated Foraminifera have been described from North America, the Baltic and England, and Radiolaria are occasionally reported, but little is known in detail of these Silurian records.

An important group of Silurian problematica is the Chitinozoa, consisting of minute, black, chitinous, vase-shaped to club- or ball-shaped organisms. Revelation of such tiny creatures or parts of creatures by chemical treatment of apparently unfossiliferous rocks sometimes permits the correlation of deposits whose position cannot be closely established by other methods.

3. Fishes, Land Plants and Associated Fossils.—Silurian occurrences of fish and plant fossils are more numerous and complete than in older rocks. They are, however, mostly, though not entirely, restricted to the upper part of the system and the fossils are not demonstrably more advanced than their predecessors.

DISTRIBUTION OF SILURIAN SEAS AND LANDS

Conversely, they are greatly surpassed in number and variety by Devonian records. In the Late Silurian, in fact, the arthropods appeared to be making more headway than the vertebrates in colonizing the lands. The arachnids were represented by the scorpionid *Paleophonus*, from the Upper Silurian of both sides of the Atlantic. Millipedes are reported to occur in association with eurypterids (water-dwelling scorpionlike creatures) in Wales. Neither scorpion nor millipede was surely air breathing, but both were at least evolving in that direction. In the estuarine to questionably marine or fresh water deposits, where the early fishes are most commonly found, is also an abundance of eurypterid remains. Indeed the Silurian and Devonian saw the climax of this group, which comprised the greatest arthropod predators of all time, perhaps including principal foes of the early fishes, and possible ancestors of the arachnids.

The simple, externally armoured, mainly backboneless earliest fishes and the primitive early plant assemblages are discussed in a separate article on the Devonian system (*q.v.*).

III. REGIONAL SUMMARY

The distribution map shows where Silurian marine deposits of different ages might have been laid down on the present land areas. Naturally a map for any instant of the 30,000,000 years or so of Silurian time would look very different from this highly generalized scheme, particularly if the Paleozoic geology of the ocean basins were known. Silurian nonmarine deposits and plutonic rocks are not well enough known to consider on a composite map of this scale. This map and the correlation table together give a general view of Silurian stratigraphy and paleogeography that supplements the condensed discussion of outcrop regions below.

1. Great Britain.—Silurian sediments of the type region in Wales and western England, and extending into southern Scotland, were deposited in a northeast-southwest trending subsiding area (the Caledonian geosyncline) and bordering shelf seas to the east. The basin or geosynclinal facies is characterized by graptolite-bearing slates and shales, flaggy and shaly silt stones, sandstones and mixed coarse detritus about 5,000 to 10,000 m. thick. This facies is typically developed in the Lake district of northwestern England. The shelf facies consists of shales (including mudstones), limestones and silt stones with a shelly fauna and a maximum thickness of perhaps 1,000 m. in typical development. It thins eastward to disappear toward the inferred Silurian seashore. Complete gradation in sedimentary facies, thickness and fauna occurs from shelf to basin along the margins of the subsiding trough, with some persistent zones of graptolitic shale that correlate between facies and record the history of down warping. The type area of south Wales and the Welsh borderland is happily intermediate between extreme developments of either shelf or basin facies. Northward, to the south of Scotland, the sediments suggest approach toward the northwest side of the geosyncline.

At many places in the Welsh borderland the oldest Silurian deposits in Britain are separated from underlying rocks by unconformity or abrupt upward reduction of volcanic components. Preceding crustal movements, of which the profuse Ordovician volcanicity is one indication, may have brought the southeastern part of the British subsiding area generally above water in the waning stages of the Ordovician. Subsidence, with sharply waning volcanism, was almost immediately renewed, however, and continued intermittently to near the end of the Silurian or beyond. Onset of the Caledonian orogeny forever reversed the process and made mountains where the sea had been, from Wales to Scandinavia.

Subdivisions of the British sequence are shown on the correlation table. The oldest interval, the Llandoverian (or Valentian, or May Hill), saw the sharpest distinctions between basin graptolitic shale facies and calcareous and in part sandy shelf facies. This distinction was less marked in the Wenlockian or middle division, when the importance of the calcareous facies was increased by growth of coral-stromatoporoid reefs and colonies on the shelf and spread of shelly fossils into the graptolitic shales. In

Ludlovian or Upper Silurian time the distinction became progressively less marked. It finally disappeared in the last half of the Ludlovian (Aymestry) along with general faunal impoverishment and disappearance of the graptolites from Britain.

2. European Continent.—The same Caledonian depression in and along which were deposited the Silurian sediments of Britain, continued northeastward to Scandinavia, with a bordering shelf sea that locally extended as far eastward as Estonia. Best-known Scandinavian sequences are in southern Norway, southern Sweden and Gotland. That of south Sweden (Skåne) is a somewhat deformed but essentially complete basin succession of graptolitic shales with limestone interbeds increasing toward the top. This grades northwestward to the fine-textured and richly fossiliferous, but also structurally disturbed, intermediate to platform facies of limestones and shales north of Oslo. Southeastward it goes into the thin, calcareous, relatively flat lying shelf-facies of Gotland and Estonia. The Caledonian trough of pre-Silurian time thus seems now to have shifted its axis to the east and to have become a broad but not very deep embayment bulging northeastward into but not across Scandinavia. Later Caledonian deformation from a northwest direction folded the Norwegian sequence and that of south Sweden but did not noticeably affect Gotland or the eastern Baltic.

The Silurian section of Gotland, important because it comprises the type Gotlandian (synonym of Silurian as here used) is a thin but richly fossiliferous succession of limestones and calcareous shales. Many of the hills of Gotland are coral-stromatoporoid reefs, marvelously exposed for study. Despite its importance and fine shelly faunas, agreement has not been reached as to names, limits, or number of subdivisions for the Gotlandian section.

Between the Baltic and Brittany, the Silurian is represented by poorly developed and little understood shales, sandstones and limestones, commonly strongly metamorphosed and discontinuous. Only eastward in the Harz and Thüringer uplifts does the section improve, with Bohemian aspects. The Armorican massif itself (Brittany) displays a basinal Silurian facies—500 m. or so of graptolitic black shales, with sandstone at the base.

In the Bohemian (or Czechoslovakian) massif around Prague is the famous Silurian sequence of Joachim Barrande and J. Perner; somewhat deformed by Caledonian as well as by later movements. This is prevailingly of graptolitic shales with at first inconspicuous limestone bands. The calcareous fraction increases toward the top until the whole sequence goes over to gray and black limestones, with both bedded and reef facies. Total thickness is somewhat under 200 m. A thin sandstone with land plants near the top is followed by shale and limestone with the last known uniaxial graptolites. This sequence represents a large span of Silurian time during which sediments presumably accumulated in a relatively shallow or slowly subsiding basin which connected through Brittany to the Caledonian seas. It also spilled over through the Montagne Noire of south central France and had connections to Elba, Sardinia, Spain, the eastern Bavarian Alps and the Balkans, where Silurian rocks generally resemble those of central Czechoslovakia.

3. U.S.S.R.—The so-called Tethyan seaway connected through the present site of the Alps, Mediterranean and the northern middle east to the Uralian trough and Siberia during parts of Silurian time. It left about 400 m. of richly fossiliferous marine Wenlockian and Ludlovian calcareous shales and limestones in Podolia, southwest Ukraine (formerly southeast Poland). The beds dip slightly westward along the walls of deeply entrenched streams beneath a cover of younger deposits, to disappear under Downtonian (basál Devonian) marine deposits and the Old Red Sandstone.

The north-south trending Uralian subsiding belt lay on the eastern side of the north European heartland and extended beyond Spitzbergen presumably to the north of Greenland and the northern islands of the Canadian Arctic archipelago. It developed independently, and its Wenlockian and Ludlovian shelly fauna is more like that of southeastern Alaska and northern California than to anything else well known. Presumably there was a direct connection across central Siberia and the Aleutian area at this time. Graptolites occur in Llandoverian shales and sandstones of the Urals. The Silurian of the Altai mountains of south central Siberia consists of shales and limestones with graptolites and corals, at places reefy.

4. Asia.—Limestones and sandstones with corals, brachiopods and graptolites are known from Spiti and Kashmir at the north of the Indian continent, and in the Shan states of Burma, where graptolites establish Early and Middle Silurian age. Total thickness may not exceed 300 m.

Connections are from the Tethyan or Mediterranean area to southwest China, where (in east and central Yünnan) there are about 1,000 m. of fossiliferous shales, sandstones and limestones of Llandoverian and Ludlovian age. Llandoverian deposits, in fact, occur widely in western and central China, but the Ludlovian is known only in the southwest, and the Wenlockian nowhere at all. The record in north China is obscure.

The Kitakami mountains of north Japan (north Honshu) reveal 200 to 300 m. of Middle and Upper Silurian limestones and slates, with corals and stromatoporoids in the limestones and radiolarians in slates near the series boundary. Silurian is also reported from central Honshu and the islands of Shikoku and Kyushu.

In Celebes is a Silurian outpost between Yünnan and eastern Australia, identified by the coral *Halysites*.

5. Australia.—The known Silurian of Australia is limited to the eastern coast and Tasmania. A thick (3,000 m.) conglomerate in the centre (Macdonnell ranges) has been tentatively referred to the Silurian for obscure reasons, but no fossils are known from it. Known Silurian sections consist dominantly of coarse clastic and volcanic deposits. Interbedded with these locally are graptolitic shales and limestones or calcareous shales with a shelly fauna. Northeast of Melbourne are 8,000 m. of clastic beds that may represent the whole of the Silurian. In the Yass district of New South Wales the section is only about 1,000 m. thick, but is famed for the rich and beautifully preserved fossils of its Yass beds and lower Hume limestones and shales.

Silurian crustal unrest, indicated by prolonged and widespread volcanic activity, culminated with compressive movements and deep-seated igneous intrusions locally termed the Bowning orogeny, and considered a phase of the more inclusive Caledonian orogeny. When the Devonian seas reinvaded eastern Australia their deposits frequently came to rest on the folded and erosionally truncated edges of Silurian rocks.

6. South America.—A compilation of South American paleogeographic data by Kenneth Caster shows broad invasion of that continent by the Silurian seas. The details, however, are little known and difficult to interpret, because Silurian was lumped with Ordovician in the reconnaissance studies that so long characterized South American geological exploration. Between South America and Antarctica, detrital and volcanic deposits at the base of the Cumberland bay series of South Georgia Island are questionably referred to the Silurian on doubtful fossil evidence.

7. North Africa.—Silurian deposits throughout north Africa are prevailingly in the basin facies. They imply a broad, open, but not very rapidly subsiding sea that connected freely with the Tethyan (Mediterranean) and north European seaways. In central Morocco the entire succession, save the top fraction, consists of graptolitic shales with characteristic species of most of the British stages. Altogether it is about 1,000 to 1,500 m. thick. This facies continues not only through the Great Atlas, where an axis of subsidence might be expected, but also southward, to the middle of the Sahara shield.

8. North America.—The Silurian rocks of North America are mainly the deposits of warm platform seas, which deepened in the eastern U.S. to form the Appalachian trough. Detrital sediments originating in eastern borderlands were largely restricted to this trough, and some (with fishes and eurypterids) along its eastern side may be nonmarine or very near shore. Leaving aside the Acadian deposits, with their European affinities, the gross form of the Appalachian succession is that of a wedge of sandstones, shales, carbonate rocks and some conglomerates from 300 to 2,000 m. thick—like a giant composite delta. By contrast, equivalent strata on the west side of the trough and the east flank

of the Cincinnati arch are greatly reduced and are here already within the interior platform seas. Prevailing aridity over and adjacent to the Late Silurian seas from western New York state to southern Michigan led to the accumulation of commercial deposits of gypsum and salt in arms of the sea or intermittently connected salt basins. These evaporites are interbedded with green and red shales and grade eastward to coarser and partly red detritus. During parts of the Middle Silurian unusual (and uncertain) conditions led to deposition of the famous hematitic Clinton iron ores from New York to Alabama. The iron replaces formerly calcareous shell fragments and is deposited between them in stratigraphically limited zones of varying thickness. Graptolitic shales are also found in some of the Appalachian trough deposits, although not as common as in the good basin developments of Europe and north Africa.

Little mud or sand entered the Silurian seas west of the Cincinnati arch, and the sediments there were thin, almost entirely calcareous, and locally include reefs. Thus, sequences of limestone generally less than 300 m. thick are prevalent in the Mississippi valley. Limestone is also a common rock of the Silurian in central Canada, southwest of Hudson bay and in the Acadian region at the eastern apex of the continent; for instance, in eastern Quebec (Chaleur bay), northern Nova Scotia (Arisaig) and Anticosti Island. The interior limestones grade to dolomites in the shallower parts of the ancient seas, especially in the Great Lakes region. The Silurian has restricted development in the eastern Great Plains and the subsurface of north central Texas, but richly fossiliferous limestones and shales are exposed in the Arbuckle mountains of southern Oklahoma.

Development in the Cordilleran region is almost restricted to the U.S., with an arm along the Mexican border to west Texas. There it is preponderantly dolomite, with limestone and shale subordinate and with identifiable fossils only locally. In the Eureka district of central Nevada the section is as much as 1,400 m. thick. The Pacific border deposits of California and Alaska are coarse, impure, detrital and volcanic sediments with occasional fossiliferous limestone lenses and with Siberian and Uralian faunal affinities. Those of the North American arctic seem to be mainly calcareous, dolomitic or shaly. *See* also references under "Silurian System" in the Index.

(P. E. Cd.)

SILVA, ANTÓNIO JOSÉ DA (1705–39), Portuguese playwright, also known as "O Judeu" (The Jew), who was an important figure in the revival of drama in 18th-century Portugal. He was born at Rio de Janeiro, Brazil, the son of Portuguese Jews, with whom he went to Lisbon in 1712. In spite of initial hardship, resulting from persecution under the Inquisition, he began to study law at the University of Coimbra. In 1726 he was imprisoned with his mother and brothers, and, under torture, abjured his Jewish faith. He was set free and in 1728 completed his studies. He returned to Lisbon, joined his father's legal practice, and married a cousin, who had also suffered religious persecution. They were both charged with heresy by the Inquisition and imprisoned on Oct. 5, 1739. António was first condemned to an auto-da-fé but on Oct. 18 he was strangled and his body burned.

Silva wrote eight plays, all produced at the Bairro Alto theatre in Lisbon. These were *A Vida do grande D. Quixote de la Mancha* (1733), *Esopaida* (1734), *Los Encantos de Medeîa* (1735), *Anfitrião* (1736), *Labirinto de Creta* (1736), *Guerras do Alecrim e da Mangerona* (1737), *As Variedades de Proteu* (1737), and *Precipício de Faetonte* (1738). They were written for the *ópera dos bonecos* (puppet theatre) in a new style, developed under the influence of Italian opera and Spanish and French comedy, which consisted of a mingling of prose dialogue and popular lyrics. They form a skilled and witty satire against the pretensions of a society based on caste and privilege.

Bibliography.—Three of da Silva's plays were published anonymously, *Labirinto de Creta* (1736); *Variedades de Proteu* (1737); *Guerras do Alecrim e da Mangerona* (1737), as were also the first two volumes of the collection *Teatro Cómico Português* (1744). *Obras Completas* were ed. by José Pereira Tavares, 4 vol. (1957–58). *See* also Teófilo Braga, *História do Teatro Português; a baixo comédia e a ópera* (1871); articles by Claude Henri Frèches in *Bulletin d'Histoire du Théâtre Portugais*, vol. I, no. I (1950); vol. II, no. I (1951); vol. IV, no. I (1953), and in *Bulletin des Études Portugaises* (1952); João Lúcio de Azevedo, "O Poeta A. J. da Silva e a Inquisição," in *Novas Epanáforas* (1932); Luís de Freitas Branco in *A Evolução e o Espírito do Teatro em Portugal*, vol. II, pp. 114–115 (1949). (L. de S. R.)

SILVANUS, an ancient Roman god of the countryside, similar in character to Faunus (*q.v.*), normally depicted in the guise of a countryman, as befits one whose worshipers were mostly peasants. Initially the spirit of the unreclaimed woodland fringing the settlement, he had some of the menace of the unknown. But he had a footing in the cultivated land as well as in the wilderness, and when clearings pushed back the forest he evolved into a god of woodland pastures, of boundaries, and of villas, parks, and gardens. He never enjoyed a state cult or temple, priesthood, or official festival, but the simple ritual of his private worship beneath a sacred grove or tree, with its frugal offerings or sacrifice at an often improvised altar, had a universal appeal, particularly to humble folk in all parts of the Roman Empire. In Italy, where little woodland remained, Silvanus was the patron of smallholders or small-scale cattle farmers. Outside Italy he was especially venerated by those connected with forests—huntsmen, lumbermen, timber merchants. In the provinces his cult often fused with that of local divinities; thus the Illyrian rural god equated with Pan by the Greeks became Silvanus under the Romans. In Latin literature his character tended to merge with that of Silenus or Pan (*see* Pan; Satyrs and Sileni) and to be assimilated to the Greco-Roman mythological tradition. (D. E. W. W.)

SILVER, a metallic element known from very early times. Its chemical symbol is Ag (from the Latin *argentum*), atomic number 47, and atomic weight 107.870; its melting point is 960.5° C, and its density at 20° C is 10.49. Together with gold, iridium, palladium, and platinum it is one of the so-called precious metals and, because of its comparative scarcity, brilliant white colour, malleability, and resistance to atmospheric oxidation, has long been used in the manufacture of articles of value such as coins, ornaments,

and jewelry. Apart from these uses, silver has a number of applications, most of which depend on its high thermal or electrical conductivity and corrosion resistance. Silver which has been hardened by elements such as copper or gold is used in electrical contacts. In electronic engineering conductors are sometimes coated with silver for radio-frequency currents, where the skin effect is important.

Silver apparatus is used to a limited extent in the chemical engineering industry, for example, in the manufacture of certain medicinal chemicals, in processing foodstuffs and beverages, and in handling organic acids such as citric and lactic acids. Silver functions as a mild oxidation catalyst in the vapour phase oxidation of certain organic compounds such as the lower aliphatic alcohols.

The silvering of glass mirrors is an old-established industry and depends on the action of a chemical reducing agent such as invert sugar, Rochelle salt, or formaldehyde on an ammoniacal silver solution. It is also possible to produce mirrors by evaporating silver on to a surface from an electrically heated filament in high vacuum.

HISTORY

Early Roman records show that before the use of the term *argentum*, the word "Luna" and a crescent moon symbol were used for silver. The actual use of silver dates far back into antiquity; however, it is believed that gold and copper were the first metals to be worked by man. Silver ornaments and decorations have been found in royal tombs dating back as far as 4000 B.C. In the Code of Menes, who is supposed to have reigned in Egypt about 3100 B.C., it was decreed that "one part of gold is equal to two and one-half parts of silver in value." This may have been the first gold standard. By 800 B.C. it is probable that both gold and silver were used as money in all countries between the Indus and the Nile. The Romans probably advanced the art and science of metallurgy of silver further than any other people up to their time. The Romans had several large and important silver workings, using perhaps the first fire metallurgy (pyrometallurgy) to produce silver metal and then converting the metal into priceless silver ornaments.

According to Pliny in his *Historia naturalis*, "the ore was washed and sieved five times, fused with lead and then cupelled for pure silver." Cupellation is the process of oxidizing the lead to lead oxide, which is quite volatile at high temperatures (*see* ASSAYING). Several centuries later it was found that certain ores of gold and silver could be amalgamated by grinding in the presence of iron or copper salts, water and mercury. This method finally evolved into the patio, or Mexican process (*see* AMALGAMATION). The cyanide process (*q.v.*) for the treatment of gold and silver ores, developed in the latter part of the 19th century, was largely superseded in the 20th century by flotation combined with smelting. From about 1850, 65% or more of the world production of silver was derived as a by-product in the smelting and refining of copper, lead, and zinc ores.

OCCURRENCE

Silver is widely distributed in nature, but the total amount present in the lithosphere is quite small when compared with other metals. For every 10,000,000 parts of iron found in the lithosphere, there are about 2 parts of silver. Practically all sulfides of lead, copper, and zinc contain some silver, and in general if the three different metal sulfides occur in the same ore, the largest per cent of the silver will be found in the lead sulfide (galena). These are called argentiferous ores.

Argentiferous ores may contain amounts of silver from a trace to several thousand troy ounces per avoirdupois ton or about 10%.

Unlike gold, silver tends to form many naturally occurring minerals. Among the most important are argentite (silver glance), Ag_2S, and cerargyrite, or chlorargyrite (silver chloride, or horn silver), $AgCl$; also polybasite (silver antimony sulfide) $Ag_{16}Sb_2S_{11}$, proustite (silver arsenic sulfide) Ag_3AsS_3, pyrargyrite (silver antimony sulfide) Ag_3SbS_3, and stephanite (also a silver antimony sulfide) Ag_5SbS_4. Deposits of native (chemically free, or uncombined) silver are also commercially important. Sylvanite

DRILLING UNDERGROUND IN A SILVER MINE. WIRE NETTING PROTECTS MINERS DURING BLASTING

(gold, silver telluride) (Au, Ag) Te_2 has been mined as an ore of both metals. (*See* also ORE DEPOSITS.)

The world's largest silver mine, the Real de Monte y Pachuca, is in Hidalgo, Mex. In the United States, the Comstock Lode discovered in 1859 near Virginia City, Nev., proved to be one of the richest gold and silver deposits in the world; other important occurrences include those in the Coeur d'Alene district of Idaho, and in Utah, Arizona, Colorado, and a number of other states. In Canada, silver is found in the Canadian Shield, as at Sudbury and Cobalt in Ontario, and in the west in British Columbia and the Yukon Territory. Silver deposits in the highlands of Peru, as at Cerro de Pasco, have been worked since the 17th century. Important silver-lead-zinc ores occur in Australia at Mt. Isa and North Broken Hill. Smaller but still important occurrences are widespread.

METALLURGY

Several methods are employed for the extraction of silver, or gold and silver from the ores. It must be realized that the majority of ores that contain silver also contain the base metals, lead or copper or zinc, or any combination of these three metals, and are treated metallurgically mainly for the three. The silver they contain is removed as a by-product. Under certain economic conditions it may be more profitable to send such ores to a lead or copper smelter.

Amalgamation and the cyanide process have been mentioned above. The cyanide process is used mainly on ores in which gold is the main valuable constituent and silver a by-product. However, a large amount of the ore mined in Mexico contains only silver as the main valuable constituent and is treated by the cyanide process (*q.v.*). Other processes use flotation and smelting (*see* METALLURGY). Except for the treatment of the Mexican ores, smelting is the most widely used process. Sometimes silver ores or concentrates containing silica, lime, or iron are smelted with lead ores to help produce the desired slag and to take advantage of the properties of lead as a collector (*see* LEAD).

Refining of crude silver bullion or gold-silver bullion may be carried out by a number of methods, the method used depending to a large extent on the purity and the amount of bullion to be refined. Bullions containing a large amount of impurities may require smelting in a small furnace with lead oxide and other materials to form a slag (which can be sent to a lead smelter) and the lead bullion, which contains most of the gold and silver. The lead bullion is then cupelled. The resulting alloy, mainly gold and silver, is called doré. The most important methods of treating high-purity gold and silver bullions are electrolysis and parting.

In electrolysis the gold and silver bullions and dorés are used for the anode (positive pole). Silver and the more basic impurities are dissolved in a dilute nitrate water solution at the anode. Pure silver is deposited at the cathode (negative pole). The resulting cathode silver is melted and cast into bars. (*See* also ELECTROMETALLURGY: *Electrorefining: Silver.*)

Parting, or wet method, is generally applicable to doré or very high-purity gold and silver bullion in which the silver to gold ratio must be higher than two parts of silver to one part of gold. If the ratio is not two to one or better, then the silver must be added and the resulting alloy remelted. The doré or gold and silver bullion is placed into a bath of hot concentrated sulfuric or strong nitric acid, and the silver is allowed to dissolve. The silver forms water-soluble sulfates or nitrates. The residue is filtered off and treated for its gold content. The clear solution containing the silver is treated with ferrous sulfate or copper or iron to precipitate the silver. The resulting precipitate is filtered off, washed, dried, and melted down with flux to give a product that averages 99.5% silver or 995 fine of silver.

Mechanical and Working Characteristics.—In the molten state silver dissolves oxygen (at the melting point about 20 vol. are dissolved per volume of molten silver at one atmosphere pressure of oxygen). Most of this is evolved on solidification, a phenomenon known as the splitting of silver; this is avoided by bringing the oxygen to a low level before pouring.

The metal can be formed by hot or cold methods; the density is lowered by cold working.

It is the most malleable and ductile of all metals except gold, and it can be beaten into leaves of less than 0.00025 mm. thickness. The pure annealed metal has a Vickers pyramid hardness of 26: it is harder than gold but softer than copper. Pure silver is too soft for use as a coinage metal or in the manufacture of jewelry, and for these purposes it is generally alloyed with a small percentage of copper, which while increasing its hardness has no appreciable effect on its colour, but does lower the melting point and thermal and electrical conductivities.

Silver has an excellent thermal conductivity. Taking it as 100 the relative values for other metals are:

Ag	Cu	Au	Zn	Sn	Fe	Pt	Pb	Bi
100	73.6	53.2	19.0	14.5	11.6	8.4	8.1	1.8

The electrical conductivity of silver is also slightly superior to that of copper. Resistivity is appreciably increased by cold working. The optical reflectivity of the freshly polished metal is about 98% for infrared light and 95% in the visible region of the spectrum. It decreases very rapidly in the ultraviolet below 3,500 Å and is only 10% at 3,200 Å.

USES

Historically, a major use of silver has been monetary, in the form of reserves of silver bullion and in coins (*see* BIMETALLISM). By the 1960s, however, the use of silver for industrial purposes exceeded total annual world production. Because of the resulting world-wide shortage, the United States in 1965 eliminated silver from its 10-cent and 25-cent coins and sharply reduced the silver content of its 50-cent pieces from 90% to 40%, marking the first major change in U.S. coinage since 1792. The U.S. Treasury announced it would use its reserve of 1,000,000,000 oz. to hold the world price at or below \$1.29+ an ounce, at least until new cupronickel and copper coins were available in quantity. No change was made in the U.S. silver dollar; the U.S. in 1963 had repealed its silver purchase laws and transactions tax, and authorized the replacement of one-dollar silver certificates by Federal Reserve notes.

Use of the metal for sterling and plated silverware, ornaments, jewelry, and similar products has continued to be important. Alloys of silver with copper are harder, tougher, and more fusible than pure silver and are used for jewelry and coinage. The proportion of silver in these alloys is stated in terms of fineness, which means parts of silver per 1,000 of the alloy. Sterling silver contains 92.5% of silver and 7.5% of another metal, usually copper; *i.e.*, has a fineness of 925. An average sterling teaspoon contains about 1 oz. of silver. Jewelry silver is an alloy containing 80% silver and 20% copper (800 fine). Gold dental alloys contain about 75% gold, 10% silver, 10% copper, and the remaining palladium, platinum, and zinc. Dental amalgams are alloys of silver, tin, and mercury. Yellow gold used in jewelry is composed of 53% gold, 25% silver, and 22% copper.

In the photography industry, silver is used in the form of halides such as silver bromide for making film and photographic plates. (*See* PHOTOGRAPHY: *Theory of Photography.*) Photochromic glass that darkens as light intensity increases and lightens when it decreases contains submicroscopic crystals of silver halide; these turn to metallic silver when exposed to light, but unlike the permanent darkening of photographic film, the silver atoms reunite when the light source is removed and the glass becomes transparent again.

Prior to World War II, manufacturers of airplanes and diesel locomotives began to use pure silver as a bearing material; such bearings have a seizure resistance of 1 compared with about 3 for babbit. After restriction on silver use was removed at the end of World War II, nearly all aircraft and diesel locomotives were equipped with silver-plated bearing sleeves.

Silver has a relative electrical conductivity of 100 compared to about 95 for copper. Silver and its alloys are used extensively in the electrical industry, mainly because of its resistance to oxidation, for switches and contact points, with expanding use of silver-copper alloy contacts in relays to control circuits in computers and tabulators. Silver-magnesium-nickel alloys are used for high-thermal-conductivity applications and in electrical instruments and relays operated at high temperatures. Silver coatings applied to ceramics, glass, and mica find wide use in electronic devices. Intricate electrical circuits, particularly for portable radios, may be made by stamping or printing a given circuit on panels with silver ink. Silver solders or silver brazing alloys make strong joints that have high resistance to corrosion. Among the soldering and brazing alloys are those based on the silver-copper-zinc and the silver-copper-phosphorus systems (*see* also SOLDERING). Special brazing alloys, including silver-aluminum, have been developed for applications requiring high strength at elevated temperatures. Silver also is used in epoxy cold solders to bond microminiature electronic devices without heat, and in conductive compounds used as an adhesive in electronic applications.

The catalytic properties of silver and its salts are used extensively to influence chemical reactions of ammonia for making fertilizers and other oxidation chemical reactions. Silver foil and plates are used for replacement of missing bone fragments. Certain silver compounds have fungicidal properties; a weak silver nitrate solution can be used to disinfect certain plants.

(S. L. S.; X.)

PROPERTIES AND COMPOUNDS

Physical and Chemical Properties.—The principal physical and chemical properties of silver are given in the accompanying table. The natural isotopes are Ag^{107} and Ag^{109} which are roughly equally abundant. Its chief radioactive isotopes are Ag^{108} (half-life, 225 days), Ag^{110} (half-life, 24 seconds), and Ag^{111} (half-life, 7.5 days). Silver is more electropositive than copper but less so than gold. The standard electrode potential is −0.7978 v. at 25° C. The metal does not react with moist or dry oxygen but is oxidized superficially by moist ozone. It is quickly tarnished by sulfur at room temperature and a surface film of silver sulfide is

Physical and Chemical Properties

Chemical symbol	Ag
Atomic number	47
Atomic weight	107.870
Crystal system	face-centred cubic
Melting point (° C)	960.5
Boiling point (° C)	2,212
Electrical resistivity at 20° C, microhm-cm	1.59
Thermal conductivity cal/cm/cm²/sec/° C	0.934(100°)
Density at 20° C, g per cc	10.49
Coefficient of linear thermal expansion /° C × 10^{-6}	19.86(0–100°)
Specific heat at 0° C, cal/g	0.0559
at 100° C, cal/g	0.0568
Periodic classification	IB

formed. A similar effect is obtained with hydrogen sulfide in presence of air or oxygen or with materials such as vulcanized rubber, which can give free sulfur. Solutions of sulfides also blacken silver.

Fluorine, chlorine, bromine, and iodine all react with silver at elevated temperatures but attack on the solid tends to be limited by protective halide films. Aqueous hydrofluoric acid and fluoride solutions do not attack silver appreciably but hydrochloric, hydrobromic, and hydriodic acid react superficially. Silver dissolves readily in either strong or dilute nitric acid, forming silver nitrate ($AgNO_3$) and nitric oxide. Hot strong sulfuric acid dissolves the metal and forms silver sulfate (Ag_2SO_4) and sulfur dioxide. When the acid strength is less than 60% there is no action up to the boiling temperature except in presence of oxidizing substances.

In the absence of air fused alkali hydroxides have no action. It is also unaffected by fused alkali carbonates or cyanides though aqueous cyanide solutions in presence of oxygen form the argentocyanide ion.

Colloidal Silver.—In addition to the highly reactive forms of silver sometimes called molecular silver, which are obtained as finely divided powders by precipitating the metal from its solutions with a reducing agent, or by reducing silver chloride with a metal such as iron or zinc in an acid solution, true colloids are readily obtained. Reducing agents commonly used in preparing colloidal silver are: formaldehyde, hydrazine salts, and salts such as tartrates or citrates. Protective colloids are sometimes added. In addition good silver colloids are obtained by passing an arc between pure silver electrodes under water. The colour of the colloids may vary from lilac to red and is largely conditioned by the particle size. Red and yellow solutions contain the smallest and blue solutions the largest particles. Colloidal silver exhibits reducing properties and, in common with some other colloids, is able to catalyze the decomposition of hydrogen peroxide.

Chemically Pure Silver.—Silver of the highest purity is of special interest to the chemist because it was made and used in all the classical work on the determination of atomic weights. A procedure used by T. W. Richards and H. Wells in 1905 may still be quoted, though various other methods are now available. Silver nitrate is recrystallized, precipitated by hydrochloric acid and the resulting chloride thoroughly washed, and reduced to metal with pure invert sugar and caustic soda. The reduced silver is fused in a block of lime in the reducing flame of a blowpipe. The product is further purified electrolytically and again melted in a lime boat in an atmosphere of hydrogen. Silver of at least 99.999% has been obtained.

Compounds of Univalent Silver.—In the majority of silver compounds the element has a valence of one. These so-called argentous compounds include such familiar substances as silver chloride, bromide, iodide and nitrate. A few argentic compounds are known in which the element has a valence of two (see below).

Silver oxide (Ag_2O) is prepared as a dark brown precipitate by adding an excess of sodium hydroxide solution to a solution of silver nitrate. It is appreciably soluble in water (0.02 g. per litre at 25° C.) and this solution has an alkaline reaction and behaves as if it contained silver hydroxide. It will precipitate many insoluble metal hydroxides from solutions of their salts, absorbs carbon dioxide from the atmosphere to form silver carbonate, and is used in organic chemistry for replacing a halogen atom by a hydroxyl group. The oxide exerts one atmosphere oxygen pressure at equilibrium at 187° C, loses oxygen slowly at 250° C, and is rapidly decomposed to silver and oxygen at [illegible] C. In its reactions it behaves as a moderately strong oxidizing agent. The oxide dissolves in aqueous ammonia probably forming the complex $[Ag(NH_3)_2]OH$. The solution on exposure to air forms a black precipitate of fulminating silver, which is dangerously explosive. Its composition is uncertain but it may contain either the nitride Ag_3N or the imide $AgNH_2$.

Halogen Compounds.—The halides of univalent silver, the most useful compounds of silver, are all well known and stable compounds. Silver fluoride (AgF) differs from the chloride, bromide and iodide in that it is readily soluble in water (182 g. of AgF in 100 g. of water at 25° C). It is obtained by dissolving silver carbonate in hydrofluoric acid and evaporating the solution in va… It forms several hydrates. The fluoride has a rock salt str… in which it resembles silver chloride and bromide but differs… the iodide. The melting point is 435° C; the fused salt de… poses slightly and contains a little free silver. A silver sub… with the formula Ag_2F is formed by the interaction of silver … ride and metallic silver at 50° C to 90° C, or in the cathodic … tion of silver fluoride. [illegible] is subsequently developed, *i.e.*, submitted to the action [illegible] chemical reducing agent, are those grains which have been [illegible] to light blackened because of the production of metallic [illegible] (*see* PHOTOGRAPHY).

[illegible] *Compounds.* Silver nitrate ($AgNO_3$) is the chief silver compound which is of technical importance. It is made in large [illegible] by dissolving silver in nitric acid of density 1.25–1.30. [illegible] in transparent plates which melt at 212° C and can [illegible] cast. The solubility at 20° C is 222 g. per 100 g. of water. [illegible] moderately soluble in methyl and ethyl alcohols and, to a [illegible] extent in various other organic solvents. When heated at about 320° C silver nitrate loses oxygen and forms silver nitrite. At a red heat silver is formed.

The chief use of silver nitrate is as an intermediate in the preparation of silver halides for incorporation in photographic [illegible]. When used for this purpose the technical salt must first be purified. In analytical chemistry aqueous solutions of [illegible] nitrate are used in the volumetric determination of halides, [illegible] and thiocyanates, as well as for the detection of reducing [illegible] and of the cations of various acids which form insoluble silver salts. Silver nitrate has a causticizing action on the skin and produces a blackening because of the formation of silver. Cast sticks of silver nitrate are used in pharmacy under the name lunar caustic. A similar blackening is produced when the salt is in contact with other types of organic matter and, in aqueous solution, it has been used for marking linen. The free nitric acid tends, however, to destroy the fabric and it is preferable to use the silver salts of weaker organic acids.

Silver sulfide (Ag_2S) is found native in the mineral silver glance or argentite. It is also found associated with the sulfides of other metals (*e.g.*, with lead sulfide). Although it is not one of the thermodynamically stable sulfides, Ag_2S may readily be formed by the direct union of the elements or by the action of hydrogen sulfide on a solution of a silver salt. It is a black-brown [illegible] which is insoluble in cold dilute mineral acids, though it dis[illegible] in hot dilute nitric acid and also in alkali cyanide solutions. It melts without decomposition at 842° C.

Silver sulfate (Ag_2SO_4) is produced when the metal is dis[illegible] in hot sulfuric acid, or by adding dilute sulfuric acid to a fairly strong solution of silver nitrate. It forms white rhombic prisms which are isomorphous with anhydrous sodium sulfate and are only sparingly soluble in water. The salt dissolves in [illegible] ammonia, the solution yielding the complex salt [illegible]SO_4.

[illegible] selenide (Ag_2Se) occurs as the mineral naumannite. It is [illegible] heating silver powder with selenium. It is a black crystal[illegible] material and a semiconductor. Silver telluride (Ag_2Te) resembles the selenide and is prepared by a similar method. Both [illegible] and tellurium may occur with silver minerals and if they [illegible] their way into the metal as trace impurities, they have a [illegible] effect on its mechanical properties as well as on its use[illegible] as a catalyst.

[illegible] cyanide is obtained as a curdy white precipitate when [illegible] cyanide is added to a silver salt solution. It is soluble [illegible] of cyanide solution and forms the complex anion [illegible]. This is important in electroplating, a process in [illegible] the object to be plated is made the cathode, the anode being [illegible] of pure silver. The electrolyte is, as a result, a solution [illegible] the complex $K[Ag(CN)_2]$, the anion of which is dis[illegible]ted to a slight extent into silver cations and cyanide anions. On electrolysis the former are deposited on the cathode to be [illegible] the latter react with the anode, causing fresh silver [illegible] into solution as the complex and so replenish the bath. [illegible] thiocyanate ($AgCNS$) is a very insoluble salt which is also [illegible] in nitric acid. It is precipitated by the addition of am[illegible] thiocyanate solution to a silver nitrate solution. Silver [illegible] (AgN_3) is formed as a white precipitate when sodium azide [illegible] added to silver nitrate solution. It resembles silver chloride [illegible] many of its reactions, but is very explosive in the dry state and [illegible] been used as a detonator.

[illegible] addition to the silver salts already mentioned there are nu[illegible] others, among which are the phosphates, arsenates, and chromates, which are insoluble and are used in testing qualitatively for the presence of these acid radicals in solution. The silver salts of many organic acids have been prepared and are of interest in that they yield silver when they are ignited in air and so may be used in determining the equivalent weight of the acid.

Silver also yields a large number of co-ordination compounds. A few of the more important, such as the complex cyanide and thiosulfate, have already been mentioned. In certain of these compounds the stability of the cation is increased by co-ordination. Thus for example co-ordination of the silver ion with ethylene thiocarbamide (etu) yields the complex chloride and bromide $[Ag(etu)_3]Cl$ and $[Ag(etu)_3]Br$, neither of which is darkened by light.

Compounds of Bivalent Silver.—One of the few simple compounds of bivalent silver is argentic fluoride (AgF_2), which is a dark brown solid formed when fluorine reacts with argentous flouride. It melts at 690° C and is a powerful oxidizing agent and also a good fluorinating agent. The other halides of bivalent silver are unknown. Anodic oxidation of silver or, alternatively, oxidation of an aqueous solution of silver nitrate with a persulfate gives a black compound of the empirical formula AgO which is very probably an oxide of bivalent silver.

There is some indication that anodic oxidation of silver may give a higher oxide, possibly Ag_2O_3. The stability of the argentic ion is much increased by coordination with various ligands. Thus, for example, although argentic persulfate is unknown, coordination of the metal with pyridine enables the relatively stable compound $[Ag\ (pyr)_4]S_2O_8$ to be prepared. It is isomorphous with the corresponding cupric compound. Other coordinating molecules which give products of a similar nature are *o*-phenanthroline and dipyridyl.

Medical Aspects.—Much of the silver which is used in medicine is in the colloidal form in association with proteins. The chief uses of silver compounds are as antiseptics, astringents, and caustics. Silver ions in water have a germicidal action, even at very low concentration, and this has been utilized to a limited extent in water sterilization.

Applied externally, silver nitrate has a limited caustic action, destroying the superficial tissues and separating the part acted on as a slough. It may be employed to destroy warts. In granular lids and various forms of ophthalmia, solutions of silver nitrate are employed.

The nitrate is both astringent and stimulating as well as bactericidal, and solutions of it have been used to paint indolent ulcers and in chronic pharyngitis or laryngitis.

External or internal medicinal administration of silver, except in large doses, causes no harmful systemic effects but continued exposure may produce a chronic form of silver poisoning which is known as argyria, and in cases of which silver is deposited in the tissues. The most marked symptom is the dark slate-blue colour of the lips, cheeks, gums, and later, of the skin.

In large doses silver nitrate is a poison, causing violent abdominal pains, vomiting and diarrhea, with the development of gastroenteritis. The treatment consists in the use of solutions of common salt, followed by copious drafts of milk or white of egg and water, and soap in water, in order to dilute the poison and thus protect the mucous membranes of the esophagus and stomach.

(H. J. Es.)

PRODUCTION

Mexico has been the leading producer of silver in the world since about 1900, followed by the United States, Canada, and Peru; these countries generally account for more than [illegible] of the world total. The U.S.S.R. and Australia also are major producers. Other producers (averaging more than 1,000,000 oz. a year) include, in Central America, Honduras; in South America, Bolivia, Chile, and Argentina; in Europe, Germany (East and West), Spain, Yugoslavia, Sweden and Czechoslovakia; in Asia, Japan and Burma; and in Africa, Republic of South Africa and Republic of the Congo.

SILVER AND GOLD WORK includes personal ornaments, utensils, vases, decorative objects, and the like, made of silver or gold, with their various alloys. This article is a historical survey and is divided into the following main sections:

For a more detailed discussion of personal ornaments of silver and gold (and other materials) *see* JEWELRY. *See* also METALWORK, DECORATIVE, especially for metalworking processes.

I. THE ANCIENT WORLD

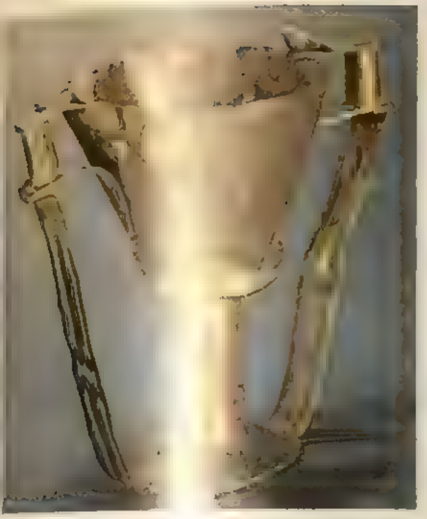
1. Pre-Mycenaean.—Gold and silver and their natural or artificial mixture, called electrum or white gold, were worked in ancient Greece and Italy for personal ornaments, for vessels, arrows and weapons, for coinage, and for inlaid and plated decoration of baser metals. Pliny notes that gold is generally found mixed with silver, and says that when the proportion of silver amounted to one-fifth the alloy was called electrum. The source of native electrum was the River Pactolus in Lydia.

Aegean lands were rich in precious metals. The considerable deposits of treasure found in the earliest prehistoric strata on the site of Troy are generally assigned to the second city; they are earlier than the sixth ("Homeric") city, and are not likely to be later than 2000 B.C. The largest of them, the so-called Treasure of Priam, is a representative collection of jewels and plate. The gold ornaments were packed in a large silver cup. They consist of elaborate diadems or pectorals, six bracelets, 60 earrings or hair-rings, and nearly 9,000 beads. The Trojan vases have bold and simple forms, mostly without ornament, but some are lightly fluted. Many are wrought from single sheets of metal. The characteristic handle is a heavy rolled loop soldered or riveted to the body. Some silver flasks with inverted cup-covers have small shoulder-studs pierced vertically for hanging. Bases are sometimes round or pointed, sometimes fitted with separate collars, but more often slightly cupped to make a low ring-foot. An odd shape in gold is an oval bowl or cup with a broad lip at each end and two large roll-handles in the middle. The oval body has Sumerian affinities, and it seems likely that Trojan arts at this time were Asiatic rather than European. Asiatic influence had indeed invaded Europe, for the oval shape occurs in the contemporary pottery of the Greek mainland and islands (Helladic and Cycladic). A plain spouted bowl of usual early Helladic shape in the Louvre is the typical specimen of goldsmith's work from pre-Mycenaean Greece, and the scarcity of precious metals points to lack of wealth as prime cause of the artistic backwardness of these regions. Silver seems to have been more plentiful in the Cyclades, but only a few simple vessels, headbands, pins and rings survive. Conditions were different in Crete.

2. Minoan and Mycenaean.—A profusion of gold jewelry was found in early Minoan burials at Mochlos, three silver dagger-blades in a communal tomb at Kumasa; silver seals and ornaments of the same age are not uncommon. An elegant silver cup from Gournia belongs to the next epoch (Middle Minoan I, c. 2000 B.C.); it is unique, but numerous imitations of its cusped and carinated form in clay, and of its metallic sheen in glazed and painted decoration, prove that such vessels were common. Minoan plate and jewelry are amply represented in the wealth of the mainland tombs at Mycenae and Vaphio. The vases from Mycenae are made indifferently of silver, gold and bronze; but gold is generally reserved for drinking-cups, small phials and boxes; silver is used for jugs as well. Much of the funeral furniture is gold, notably the masks that hid the faces or adorned the coffins of the dead. It has been thought that the small gold discs, which Heinrich Schliemann found in prodigious quantities (700 in one grave), were nailed on wooden coffins, but they may have been sewn on clothes. They are impressed with geometrical designs based on circular and spiral figures, stars and rosettes and natural forms such as leaves, butterflies and octopods. Smaller bossed discs bearing similar patterns may be button-covers. Models of shrines and other amulets are also made of gold. A splendid piece of plate is a silver counterpart of the black steatite libation-vase from Knossos in the form of a bull's head, with gold horns, a gold rosette on the forehead, gold-plated muzzle, ears and eyes. The gold here and in other Mycenaean plating is not laid on the silver, but on inserted copper strips. The gold cups from Mycenae are of two main types: plain curved or carinated forms related to the silverware and pottery of Troy, and embossed conical vessels of the Minoan tradition.[a] Some of the plain pieces have handles ending in animals' heads, which bite the rim or peer into the cup. The embossed ornament consists of vertical and horizontal bands of rosettes and spiral coils, floral, foliate, marine and animal figures. The designs are beaten through the walls and are consequently visible on the insides of the vessels; but the finest examples of their class, the two gold cups from the Vaphio tomb near Sparta, have a plain gold lining which overlaps the embossed sides at the lip. The reliefs on the Vaphio cups represent men handling wild and domesticated cattle among trees in a rocky landscape. The handles show the typical Minoan form: two horizontal plates riveted to the body at one end and joined at the other by a vertical cylinder. Steatite vases carved with similar pictorial reliefs were evidently made to imitate embossed gold. A fragment found at Palaikastro had part of its original plating attached.

Cretan and mainland tombs have produced many examples of weapons adorned with gold. Modest ornaments are gold caps on the rivets joining hilt and blade, but the whole hilt is often cased in gold. An example from Mycenae has a cylindrical grip of openwork gold flowers with lapis-lazuli in their petals and crystal filling between them; the guard is formed by similarly inlaid dragons. The most splendid Mycenaean blades are bronze inlaid with gold, electrum, silver and niello. Here again the work is done on inserted copper plates. This kind of flat inlay seems to have been originally Egyptian; it occurs on daggers from the tomb of Queen Aah-Hotep, which are contemporary with the Mycenaean (*c.* 1600 B.C.), and it is significant that two of the Mycenae designs have Egyptian subjects, though their style is purely Minoan. These are the scenes of cats hunting ducks among papyrus-clumps beside a river in which fish are swimming. Another blade bears Minoan warriors fighting lions, and lions chasing deer. A dagger from Thera has inlaid axe-heads; one from Argos, dolphins; and fragments from the Vaphio tomb show men swimming among flying fish. These are masterpieces of Minoan craftsmanship; in the long decadence of the Mycenaean age there seems to have been no invention, and later pieces of goldsmith's work repeat conventional forms and ornaments.

3. Greek and Etruscan.—The period of transition from the Bronze to the Iron Age, when Aegean external relations were violently interrupted, was not favourable either to wealth or art, and



Mycenaean gold cup, the so-called Cup of Nestor, from the royal graves at Mycenae, Greece; 1600–1500 B.C. National museum, Athens

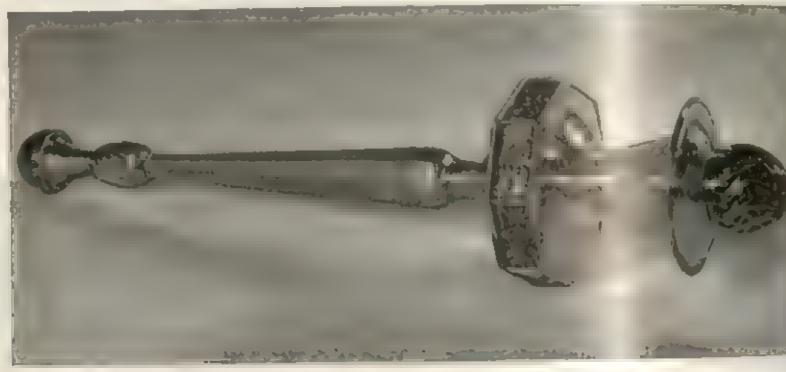
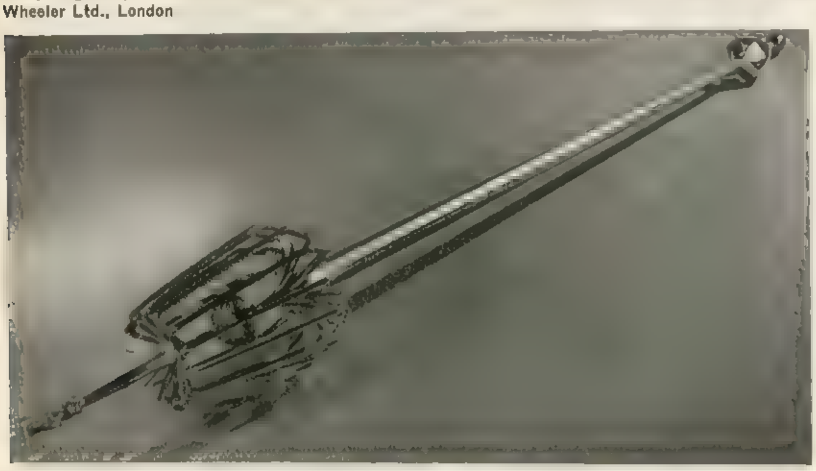
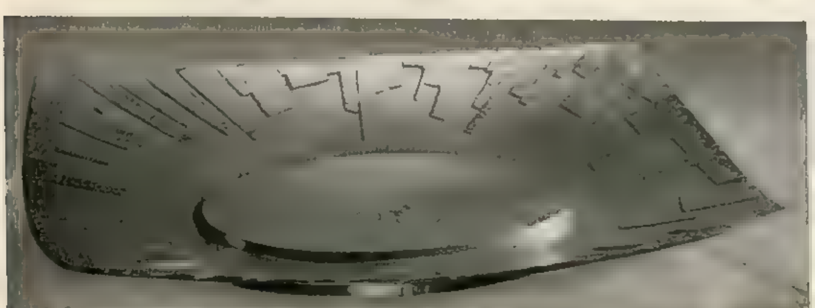
Salt and pepper pots from Corpus Christi college, Oxford, England; 1946. Designer and maker, Leslie Durbin. Given by Sir Alan Barlow



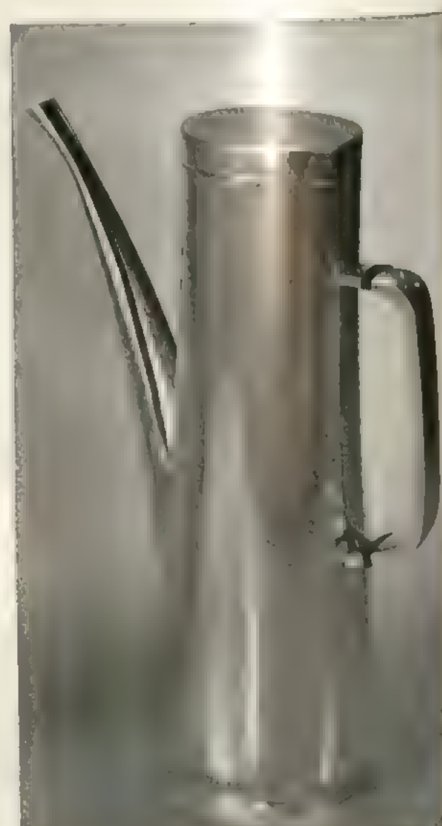
Torch commemorating the XIV Olympiad held in London in 1948. Designer, Bernard Cuzner; makers, Bernard Cuzner and Stanley G. Morris; engraver, William Biddle. Collection: Goldsmiths' hall, London



Silver and gilt mace made for Cornell university, Ithaca, N.Y.; 1962. Designer, Eric Clements; makers, Wakely and Wheeler Ltd., London



Dish presented to Lincoln hall, University of Nottingham, Eng., by Sir Francis Hill; 1962. Designer and maker, Desmond Clen-Murphy



Large coffee pot; 1962. Designer, Keith Redfern; maker, Tom Boucher. Collection: Goldsmiths' hall, London

20TH-CENTURY SILVER WORK

PHOTOGRAPHS, THE WORSHIPFUL COMPANY OF GOLDSMITHS, LONDON

the only considerable pieces of plate that have come from Greece are the embossed and engraved silver bowls made by Phoenicians. Most of them bear elaborate pictorial designs of Egyptian or Assyrian character, and are evidently foreign to Greece; but some simpler types, decorated with rows of animals in relief or wrought in the shape of conventional flower bowls, can hardly be distinguished from the first Hellenic products. Early Greek work is rare. A severe and elegant silver bowl in the Metropolitan Museum, New York, represents the flower type in its finest style. It is cast and chased, and probably belongs to the 5th century B.C. A gold treasure from Panagyurishte in Bulgaria gives a more complete idea of Greek goldsmiths work.

Silver vases and toilet instruments have been found beside the commoner bronze in Etruscan tombs. A chased powder-box of the 4th century is in the Metropolitan Museum, New York. The bronze reliefs of the archaic chariot in the same collection have their opulent counterparts in some hammered silver and electrum fragments in London, Munich and Perugia. The electrum details are attached with rivets.

4. **Roman.**—About the 4th century B.C. there was revived the fashion of ornamenting silver vessels with relief, and this type of work, elaborated in the Hellenistic age and particularly at Antioch and Alexandria, remained the usual mode of decoration until the end of the Roman Empire. Various fabrics of molded pottery correspond to the successive styles of metalware. A silver vase in the British Museum, bearing a frieze of chariots between floral bands, is nearly a reflex of an earthenware Calene bowl (3rd century B.C.) in the same collection. Pliny names Greek silversmiths whose work was valued highly at Rome, and laments the disappearance of the art in his own day. He must refer only to its quality, for Roman silverware has been abundantly preserved. Many rich hoards in modern collections were buried by design during the calamitous last centuries of the ancient world, and the most sumptuous, the Boscoreale treasure, was accidentally saved by the same volcanic catastrophe that destroyed Herculaneum and killed Pliny. This treasure is mostly in the Louvre. A slightly smaller hoard found at Hildesheim, and now in Berlin, also belongs to the early Empire. The acquisition and appreciation of silver plate was a sort of cult at Rome. Technical names for various kinds of reliefs were in common use (emblemata, sigilla, crustae), weights were recorded and compared and ostentatiously exaggerated. Large quantities of bullion came to Rome with the spoils of Greece and Asia in the 2nd century B.C., and Pliny says that even in republican times there were more than 150 silver dishes in the city of a hundredweight apiece. Weights of vessels are often marked on their bases.

Cups and jugs of Augustan style are usually covered with ornament in high relief. The subjects are very diverse: historical, mythological and mystic scenes, formal and naturalistic designs of flowers and foliage, graceful studies of animals and birds. Others have conventional fluting, petals or gadroons, Bacchic instruments and masks, embossed or engraved wreaths, gilt or inlaid with niello. Silver and niello inlay was commonly applied to bronze plates. A singular type of silver bowl (patera clipeata) has a central ornament in high relief or even in the round: portrait busts are not uncommon in this place. In course of time the ornament was restricted, and later Roman plate is largely plain with narrow border-friezes, small central medallions, and handles embossed in low relief. One of the very few gold pieces that survive, a shallow bowl found at Rennes and now in the Bibliothèque Nationale of Paris, is exceedingly elaborate. It measures 25 centimetres across and weighs 1,315 grams. The central medallion and its surrounding frieze contain scenes of a bibulous contest between Bacchus and Hercules; between these and the edge is a row of 16 gold coins each framed in a foliate wreath. The coins range from Hadrian to Caracalla. In the same collection are several examples of very large silver plates (clipei or *missoria*), in which the whole field is embossed with mythological or historical subjects. The largest (called the Shield of Scipio) is 72 centimetres in diameter and weighs 10,300 grams. Another bears the name of Gelimer, king of the Vandals and Alans (6th century). The "Shield of Theodosius" at Madrid shows the emperor seated between Valentinian and Arcadius among his guards, with an allegorical group in the exergue. (E. J. F.; M. C. Rs.)

II. EUROPE

A. Early Christian and Medieval

1. **Early Christian Period.**—*Silver.*—The earliest Christian silver work closely resembles the pagan work of the period in its naturalistic grace, ornament, and use of the traditional techniques of embossing and chasing. Even the subject matter is sometimes classical: the late-4th-century casket of Projecta, part of the Esquiline treasure found at Rome and now in the British Museum, London, is decorated with pagan scenes, and only the inscription shows that it was made for a Christian marriage. Among the few pieces with Christian subjects are the small Roman cruets from Taprain, Scotland (Royal Scottish Museum, Edinburgh, and in the British Museum) and the small pyx (casket for the reserved sacrament) from Pula, Yugos. (Kunsthistorisches Museum, Vienna).

Most of the silver of the latter part of the period has been found in the Christian east, in Syria, Egypt, Cyprus, Asia Minor, and Russia and is mostly "church" plate (chalices, censers, candlesticks, and bowls and dishes probably used as patens). Secular plate was also decorated with religious subjects, for example the dishes depicting the life of David (Cyprus Treasure, Nicosia Museum, and Metropolitan Museum, New York); and both dishes and vessels were produced with pagan subjects, like the Concesti Amphora, or the Silenus Dish (both in the Hermitage, Leningrad). The figure style is often harder and flatter than previously, characterized by strictly frontal positions and symmetry. The techniques of chasing and embossing still predominated, but abstract patterns and Christian symbols inlaid in niello (a black silver alloy) were used increasingly. The appearance of imperial "control stamps," early forerunners of hallmarks, show most of this material to be of the 6th and 7th centuries. It is not known which cities were important centres of production, but the Eastern capital, Constantinople, must have been foremost among them.

Gold.—Of work in gold of the earliest Christian period only personal jewelry has survived, but from the 6th and 7th centuries onward other pieces are also extant. Among the most important of the latter are the votive crowns and crosses offered to the churches in Spain and Italy by royal patrons, the finest being those found at Guarrazar (Toledo Province), which are inlaid with garnets and set with jewels (National Archaeological Museum, Madrid, and Musée Cluny, Paris); the cross of King Agilulfo, and a pair of gold book-covers inscribed by Queen Theodolinda (both at Monza Cathedral, Italy) set with pearls, gems and cameos and decorated with gold cloisonné work (compartments divided by narrow strips of metal filled with inlay) inlaid with garnets, a popular style for jewelry among the Germanic peoples. This cloisonné jewelry, inlaid with garnets, paste, or millifiori glass, reached an especially high standard of workmanship in Britain, as is shown by a purse lid, a sword and jewelry from the cenotaph to an East Anglian king (A.D. 650–660) discovered at Sutton Hoo, Suffolk, and now in the British Museum. Major works in silver and gold were also produced in the northern Hiberno-Saxon school and in the service of the Celtic church; work in precious metal, such as the buckle on the Moylough belt-shrine and the Ardagh Chalice (both in the National Museum, Dublin), displays the same masterly synthesis of the northern arts and humanist Mediterranean tradition as is exemplified in the Lindisfarne Gospels (*c.* 700; British Museum).

2. **Carolingian and Ottonian Period.**—The earliest works of the Carolingian renaissance, made in the last quarter of the 8th century, resemble Hiberno-Saxon art of the 8th century in their abstract treatment of the human figure, their animal ornament and their use of niello and "chip-carving" technique; examples are the Tassilo Chalice (Kremsmünster, Austria) and the Lindau book-cover (Pierpont Morgan Library, New York). From about A.D. 800 onward, however, the influence of the Mediterranean tradition gained strength at Charlemagne's court at Aachen and later spread through the whole empire. The triumphal arches (now lost) given by the emperor's biographer Einhard

(*q.v.*) to Maastricht cathedral were typical of this movement; they were miniature versions (22 cm. high) of the great marble triumphal arches of antiquity embossed in silver with Christian subjects. The bulk of work in precious metals which survives from the Middle Ages is ecclesiastical. Golden altars, like that of S. Ambrogio in Milan (*c.* 850), where scenes from the life of Christ and St. Ambrose are framed by panels of cloisonné enamel and filigree; reliquaries and book-covers in gold and silver, set with gems and decorated by embossed figures and scenes—for example, the cover of the Codex of St. Emmeram of Regensburg (*c.* 870; Staatsbibliothek, Munich)—all these testify to the magnificence of Carolingian work whose techniques were to dominate the goldsmith's craft until the 11th century. Patronage throughout this period was mainly in the hands of the emperors and the great princes of the church, and the form of liturgical plate and reliquaries, altar crosses, etc., underwent no fundamental change; Ottonian work of the later 10th and 11th centuries can be distinguished from that of the 9th only in the development of style. The larger, more massive figures on the golden altar (*c.* 1023) given by Henry II to Basel Minster (Musée Cluny), for example, with their strict pattern of folds, are markedly different from the nervous, elongated figures of the Carolingian period.

3. Romanesque Period.—In the 12th century the church supplanted secular rulers as the chief patron of the arts and the work was carried out in the larger monasteries. Under the direction of great churchmen, for example, Henry of Blois, bishop of Winchester, or Abbot Suger of Saint-Denis, near Paris, a new emphasis was given to subject matter and symbolism. The techniques of the time are expounded in a book of instructions, *De diversis artibus,* written by Theophilus, a priest who worked in Germany in the early 12th century. Craftsmen were no longer anonymous; work by Roger of Helmarshausen, Reiner of Huy, Godefroid de Claire, Nicholas of Verdun and others can be identified, and the parts they played as leaders of the great centres of metalwork on the Rhine and the Meuse are clearly recognizable. Their greatest achievement was undoubtedly the development of the brilliant champlevé enameling (in which compartments are hollowed out of the surface of the metal and filled with enamel), a method which replaced the earlier cloisonné technique. Gold and silver continued to be used as rich settings for enamels, and as the framework of portable altars or small devotional diptychs or triptychs, and in reliquary shrines with their embossed figure work, as well as in liturgical plate.

The masterpieces of the period are the great house-shaped shrines made to contain the relics of saints; for example, the shrine of St. Heribert at Deutz (*c.* 1160), or Nicholas of Verdun's shrine of the Three Kings at Cologne (*c.* 1200). In the latter, the figures are almost free-standing, and in their fine rhythmic draperies and naturalistic movement they approach the new Gothic style.

4. Gothic Period.—The growing naturalism of the 13th century is notable in the work of Nicholas' follower, Hugo of Oignies, whose reliquary for the rib of St. Peter at Namur (1228) foreshadows the partly crystal reliquaries in which the free-standing relic is exposed to the view of the faithful; it is decorated with Hugo's particularly fine filigree and enriched by the naturalistic cut-out leaves and little cast animals and birds. The increasing wealth of the royal courts, the aristocracy and, later, the merchants led to the establishment of secular workshops in the great cities and the foundation of the confraternities or guilds of gold- and silversmiths, the first being that of Paris in 1202. As in architecture, monumental sculpture and ivory carving, the lead held by Germany and the Low Countries during the Romanesque period, now passed to France. The use of architectural forms continued to be the basis of design in precious metal; for example, the silver shrine of St. Taurinus at Évreux (*c.* 1250), which is a Gothic chapel in miniature, with saints under pointed arches, clustered columns and small turrets. In England, the few pieces that survived the dissolution of the monasteries in the 16th century follow the same architectural pattern; *e.g.,* the 14th-century Ramsay Censer (Victoria and Albert Museum, London) or the magnificent crozier made for William of Wykeham (1324–1404) at New College, Oxford. Germany first produced work in the Gothic style in the second half of the 14th century with the large Gothic head-reliquary of Charlemagne and the splendid "Three-Tower" reliquary, both still at Aachen. In Italy, in spite of the undercurrent of classical taste, the Gothic style predominated in the 14th century, especially at Siena; also it was probably in Italy *c.* 1280 that *basse-taille* enamel—a technique in which intaglio relief carving in the metal below its surface is filled with translucent enamel—originated, whence it spread rapidly through the upper Rhine region to France and England. The Parisian school of enamelers predominated in the latter half of the 14th century. For the first time enough secular plate survives to show it equaled the ecclesiastical in opulence: two fine pieces are the Royal Gold Cup made in Paris *c.* 1380 (British Museum) and the so-called King John's Cup, probably English work of *c.* 1340 (King's Lynn, Norfolk).

In the late Gothic period, as well as court treasures such as the *Goldene Rössel* (Altötting, Bavaria) or the Thorn reliquary (British Museum), both early 15th century, there was an increased output of secular silver due to the rise of the middle classes; the English mazers (wooden drinking bowls with silver mounts) and the silver spoons with a large variety of finials are examples of this more modest plate. Numerous large reliquaries and altar plate of all kinds were still produced. At the end of the Middle Ages their style and that of secular plate developed more distinctive national characteristics strongly influenced by architectural style: in England by the geometric patterns of the "perpendicular," in Germany by heavy and bizarre themes of almost Baroque exuberance, and in France by the fragile elegance of the "Flamboyant."

The purity standards of silver became rigorously controlled and "hall-marking" was enforced, the marking of silver in England being especially carefully observed. *See* HALLMARK.

(P. E. LA.)

B. THE RENAISSANCE TO MODERN TIMES

1. 16th Century.—The Italian goldsmiths preceded the rest of Europe in reverting to the style of Roman antiquity but, in the absence of antique goldsmiths' work, vases of marble or bronze had to serve as models. Goldsmiths often worked from very free interpretations of the antique made by artists in other media, such as Giulio Romano (d. 1546) and Francesco Salviati (1510–63). Many of these designs but very few of the actual pieces have survived; the most famous is the enameled gold salt cellar (Kunsthistorisches Museum, Vienna) which was made for Francis I by the celebrated Florentine Benvenuto Cellini (*q.v.;* 1500–71). In the second half of the 16th century many gifted Italian and immigrant goldsmiths worked at the court of Cosimo I, grand duke of Tuscany, specializing in vessels of hardstone mounted in enameled and jeweled gold; their work is well represented in the Museo degli Argenti in the Pitti Palace, Florence, and in the Kunsthistorisches Museum, Vienna; similar work was done by the Sarachi family in Milan.

Little French goldwork is extant and most of the surviving material is in the Galerie d'Apollon in the Louvre, Paris. Among the most sumptuous pieces are a sardonyx and gold ewer, the gold St. Michael's Cup, both at Vienna, and a sardonyx-covered cup in the Louvre, which all display northern features. The massive plate of the Order of the Saint-Esprit (Louvre), dating from 1581–82, is of quite individual character and the enameled gold helmet and shield of Charles IX (1550–74) in the Louvre have no parallel for either quality or opulence.

In other parts of Europe the goldsmiths clung to Gothic forms till well into the first half of the century, especially in the provincial towns. Still immensely rich in ecclesiastical silver, Spain has little early domestic silver; Spanish silversmiths (*plateria*) gave their name to the heavily ornamented style of the period, Plateresque. Using precious metal from the New World, goldsmiths such as Juan d'Arfe (1535–1603) produced vast containers for the Host, known as *custodia.* The most important Portuguese work, Gil Vicente's monstrance (1506) for Belém Monastery near Lisbon, is still Gothic in style; later Portugal developed its

own style related to Spanish work but not copied from it.

Some of the finest 16th-century goldsmiths' work was executed in Antwerp and elsewhere by Flemish goldsmiths, such as Hans of Antwerp, goldsmith to Henry VIII, or Jacopo Delfe, called Biliverti, goldsmith to Cosimo I. The Flemish masters showed particular sympathy for the Mannerist style, derived from Italy but transformed by such native engravers as Cornelis Floris and Frans Floris the Elder. By about 1580 Dutch goldsmiths began to rival the Flemish; the van Vianen family of Utrecht won international renown, especially Adam (*c.* 1570–1627), who excelled at embossing, and his brother Paul (*c.* 1555–*c.* 1614), who worked in Italy, Munich and the workshop of Rudolph II at Prague.

The principal centres in the north were Nürnberg and Augsburg, the former particularly notable for the exuberant Mannerism of the Jamnitzer family, the latter for its ebony caskets with silver-gilt mounts. Many German princes, especially the dukes of Bavaria, maintained their own court workshops. Production was on a vast scale and great quantities survive. Characteristic German forms are columbine cups (the trial piece of the Nürnberg Goldsmiths' Guild), pineapple cups and double cups.

England is rich in 16th-century secular silver but church plate was mostly destroyed at the Reformation. The Renaissance style was introduced by Hans Holbein the Younger (*q.v.;* 1498–1543), who designed vessels for the court, and follows that of the Low Countries and Germany. Certain individual forms were also produced, such as standing salts with tiered covers and "steeple" cups which had a tall finial on the cover.

2. Baroque Period.—In the first half of the 17th century Dutch goldsmiths, such as the van Vianens and, later, Johannes Lutma of Amsterdam, developed a fleshy form of ornament, known as auricular, which became common in northern Europe, including England, where Christiaen van Vianen worked as court goldsmith to Charles I, and Germany, where the Thirty Years' War (1618–48) reduced both the quantity and quality of production. After the mid-century bold Dutch floral ornament—usually embossed in thin metal as though the pieces were for display rather than use—was characteristic and influential; France, however, undoubtedly led fashion with its state workshops at the Gobelins, the refined French acanthus ornament contrasting sharply with the coarser Dutch designs. Since Louis XIV melted the royal plate to pay his troops, no French work of this period remains but its quality is demonstrated in the work of the Huguenot silversmiths who left France after the revocation of the Edict of Nantes (1685). Mostly provincials, they brought new standards of taste and craftsmanship wherever they settled, particularly in England where the foremost names of the late 17th and earlier 18th centuries were of French origin: P. Harache, P. Platel, D. Willaume, S. Pantin, P. de Lamerie, P. Crespin, to mention but a few.

Silver furniture, a feature of the state rooms at Versailles, became fashionable among kings and noblemen: it was constructed of silver plates attached to a wooden frame and each suite contained a dressing table, looking glass and a pair of candlestands. In France such furniture did not survive the French Revolution, but much remains in England, Denmark, Germany and Russia.

After the Thirty Years' War Germany did not regain its eminence: even the enameled goldwork from the court workshops at Prague and Munich became larger and more ostentatious in colour but inferior in design and finish. In Scandinavia, particularly Sweden, goldsmiths evolved forms of beakers and tankards showing strong German influence. Spanish silver was of massive architectural design, oval champlevé enameled bosses being set at intervals over the surface of the larger pieces. The few extant Italian pieces suggest that the goldsmiths worked their material with the skill of sculptors.

3. 18th Century.—Early 18th-century English work combined functional simplicity with grace of form while the work of Dutch and German goldsmiths is in a similar style but of less pleasing proportions. The preeminence of the English work is, however, due to the destruction of all but a fraction of French silver of the same period. What survives is outstanding in originality of design and fineness of finish. Little remains of the work of Louis XV's goldsmith, Thomas Germain (1673–1748); however, there are at Lisbon three services and part of a fourth commissioned in 1756 from his son, François Thomas Germain (1726–91); at Leningrad, another service by François Thomas Germain, the famous Orloff service by Jacques Roëttiers (1707–84), and four services ordered from Robert Joseph Auguste (1725–1805) in the 1770s for Catherine II; at the Metropolitan Museum, New York, a fine collection of French provincial silver. The superiority of French work lay in its excellence of design and the high quality of the cast and chased work; where other goldsmiths worked in embossed metal, the French modeled and cast their ornament and then applied it, a technique that consumed much more of the precious material. In France provincial goldsmiths competed successfully with those of the capital, but in England all the best artists went to London. In the early 1730s the French Rococo style was imported to England and adopted by goldsmiths of both Huguenot and English descent, one of the latter being Thomas Heming, goldsmith to George III.

English Adam silver is of unequal merit owing to the introduction of industrial methods by some large-scale producers. In France Robert Auguste created pieces of great refinement in the Neoclassical style which was copied in Turin and in Rome, for example by L. Valadini. A notable workshop was founded in Madrid in 1778 by D. Antonio Martinez, who favoured severely Classical designs. In both the northern and southern Netherlands local production followed French precept, but more individuality survived in Germany. In Augsburg excellent table silver was produced and, more important, pictorial panels embossed in the highest relief by members of the Thelot family and silver furniture made by the Billers and the Drentwetts. At Dresden Augustus the Strong established under Johann Melchior Dinglinger (1664–1731) a court workshop that produced jewels and enameled goldwork unequaled since the Renaissance, and the gold snuff boxes made by Johann Christian Neuber (1735–1808) rivaled those of the Parisian goldsmiths.

4. 19th Century.—The Napoleonic adventure brought French fashions back into prominence and the Empire style developed by J. B. Odiot and M. G. Biennais was widely followed on the continent. In England the Regency goldsmiths, of whom Paul Storr was the foremost, created their own more robust version of the Empire style. Perhaps the most impressive monument of this period is the service made in Lisbon between 1813 and 1816 and presented to the duke of Wellington for his liberation of Portugal (now in Apsley House, London).

By mid-century most of the earlier styles had been revived fleetingly and a recognizably "Victorian" style evolved, based on details drawn from diverse sources. Craftsmanship was at its best, but the design of domestic silver was trivial and that of presentation pieces strove too consciously for naturalistic effect. In the latter half-century the craft became an industry and the goldsmith a factory worker. In this respect Matthew Boulton (*q.v.*) was the great pioneer: his Soho manufactory near Birmingham, which dominated the British "toy" industry from the 1770s, produced high quality steel buckles, buttons, coins, sterling silver, Sheffield plate and steam engines, establishing standards of design, of factory management and welfare services which even in the mid-20th century are seldom surpassed. However, during the 19th century these standards deteriorated and at the close of the century a second pioneering movement started—the craft revival associated with William Morris (*q.v.*) and the *art nouveau* (*q.v.*) style which led to the production of original pieces, some of doubtful merit. In England the most interesting work has been done by the sculptor Sir Alfred Gilbert (*q.v.*) who, following the lead of William Burges (1827–81), the architect and designer, combined silver with ivory and semiprecious stone in romantic confections. *See* also SHEFFIELD PLATE; ENAMEL. (J. F. H.)

C. THE 20TH CENTURY

The structure of trade, following the drastic social changes which have taken place since 1914, is similar in all industrial countries. First, a few artist-craftsmen maintain independent studio workshops, producing commercially unprofitable but artistically significant work. Many of them also teach in art schools or work

part-time in factories as industrial designers. Second, factories using modern equipment—*e.g.*, stamping, pressing, spinning, casting, vacuum evaporation and mechanical polishing—account for nearly all the financial turnover, but seldom break new ground artistically. The retail shops buy stock almost entirely from factories and wholesalers and usually sell it anonymously. The evolution of style is thus impeded by the cost of new machinery; by the natural caution of wholesalers and retailers; by the buying public which prefers precious ornaments to be timeless; and by the consideration that buying is an investment for value, rather than for beauty. In consequence the most lively designs are often those for costume jewelry, and the best modern work usually has been on a tiny scale, making little impact on the trade.

In Paris, designs by René Lalique (1860–1945) inspired the *art nouveau,* which spread to Belgium and then through Europe and the United States. In Moscow, Peter Carl Fabergé (1846–1920) set a superb standard of craftsmanship for small ornaments. In Denmark, Georg Jensen (1866–1935) with Johan Rohde (1856–1935) and others, under the enlightened patronage of the Pedersen family, not only achieved an individual Danish style but built up several large factories with retail outlets all over the world, thus proving that good modern design in silver and jewelry need not be confined to artists' studios; their influence has spread throughout Scandinavia. Wiwen Nilsson in Sweden, Raymond Templier and Jean Fouquet in Paris evolved the angular style of the 1920s. After 1935 the big factory, Gense A/B, at Eskilstuna, Swed., pioneered the use for tableware of stainless steel, first invented in England and there exploited on a smaller scale by J. and J. Wiggin at Walsall, Staffordshire. In the 1960s Germany was second only to Scandinavia in the number and quality of its artist-craftsmen, while W. M. F. (Württembergische Metallwaren Fabrik) at Geislingen is probably the biggest silverware factory in Europe. In England, notable for the most varied work, the Worshipful Company of Goldsmiths has helped a vigorous group of designers to emerge since 1945, including Gerald Benney, Eric Clements, David Mellor and Roger King. *See* also JEWELRY.

(G. McK. H.)

III. NORTH AND SOUTH AMERICA

1. Pre-Columbian.—When the Spaniards arrived in the New World in the 16th century they found a wide range of well-developed technical skills in fine metalwork in Mexico, Costa Rica, Panama, and the Andean region. They could offer little to the Indian smiths, who had already mastered cold hammering and annealing; *repoussé* decoration and chasing; pressing sheet gold over or into carved molds to make a series of identical forms; sheathing wood, bone, resin, and shell ornaments with gold foil; decorating with metal inlays and incrustation with jade, rock crystal, turquoise, and other stones; joining by clinching, stapling, and soldering; in Ecuador and Western Mexico, drawing gold wire; casting by the cire perdue method of both solid and hollow ornaments, often with false filigree or false granulation decoration; wash gilding; and colouring alloys containing gold by "pickling" in mild plant acids. There was some regional specialization, hammer work in "raising" a vessel from a flat disc of sheet gold or silver having reached its apogee in Peru, while cire perdue casting was highly developed in Colombia, Panama, Costa Rica and Mexico. The miniature, hollow cire perdue castings of the Mixtec goldsmiths in Mexico have never been surpassed in delicacy, realism and precision, and the tiny solid-cast frogs from Panama must be viewed through a magnifying glass to be appreciated. In Mexico bimetallic objects of gold and silver were made by two-stage casting; the gold part was cast first and the silver, which has a lower melting point, was then "cast on" to the gold in a separate operation. (A famous example is the pectoral of Teotitlán del Camino in the National Museum in Mexico City.) A silver llama in the American Museum of Natural History in New York indicates that the Peruvian smiths had taken the first step toward cloisonné, the cloisons being filled with cinnabar instead of enamel.

A truly great technological and artistic triumph of the pre-Hispanic workers in Ecuador was the making of complex beads of microscopic fineness from an alloy of gold and platinum, achieved by "sintering" gold dust and small grains of alluvial platinum. Platinum was not used in Europe until the latter half of the 19th century, about 500 or 600 years later.

As in other early cultures, the pre-Hispanic goldsmiths were a privileged and highly respected group, sometimes having their own patron deity such as *Xipe Totec* in Mexico or *Chibchachun* in Colombia. In Peru just before and at the time of the Conquest the goldsmith (*kori-camayoc*) is said to have been a full-time government worker, supported by the state and producing exclusively for the Inca. According to the early Mexican picture writings (codices) and the accounts of the Spanish chroniclers the craft was hereditary, the secrets being passed on from father to son.

Most of Montezuma's treasure and Atahualpa's futile ransom went directly into the melting pot, but even the conquistadors were constrained by admiration to send a few outstanding objects back to Spain intact. Some examples of the loot seen by Albrecht Dürer in Brussels in 1520 evoked his oft-quoted "Never in all my born days have I seen anything that warmed my heart as much as these things . . . ," the first professional criticism of pre-Columbian art on record. Unfortunately, what he saw then has since disappeared.

Despite Spanish greed for gold and subsequent centuries of tomb robbing and melting down the finds, many masterpieces of the goldsmith's art have come to light and survive in public and private collections. The major ones are those in the Museum of the American Indian and the American Museum of Natural History in New York, the University of Pennsylvania Museum, the Peabody Museum of Harvard University, the Cleveland Museum of Art, and the Robert Woods Bliss Collection on loan to the National Gallery of Art in Washington. Many fine examples may be seen also in the British Museum, the Musée de l'Homme in Paris, the ethnographic museums of Berlin and Hamburg, and the archaeological museum in Madrid. Mexico, Costa Rica and South America have superb regional collections, such as those in the National Museum in Mexico City, the Regional Museum of Oaxaca with the famous Tomb 7 jewels from Monte Albán, the National Museum in Costa Rica, the unique Gold Museum of the Colombian Bank of the Republic in Bogotá, and the archaeological museum in Lima, to say nothing of the private collections of Emilio Estrada and Carlos Zevallos in Ecuador, and those of Miguel Mujica Gallo and Rafael Larco Hoyle in Peru.

The earliest examples of goldwork in the New World are the sheet-gold adornments with *repoussé* decoration from Chongoyape, Peru, in the Museum of the American Indian and the Bliss Collection. They were made some time between 1000 and 500 B.C. Casting seems to have begun in Mochica times early in the Christian era in northern Peru, whence it is thought to have spread northward into Ecuador, Colombia, Panama, Costa Rica and finally Mexico. Dating in the intervening areas is problematical, but it is generally accepted that fine metalwork in gold, silver and copper did not reach the valley of Oaxaca in Mexico until about A.D. 900. Some finds in western Mexico suggest an earlier beginning date there, and also that knowledge of the craft came by sea rather than overland from South America.

It is said that the Spaniards saw some pre-Columbian goldwork when they first arrived in Florida, but none seems to have survived. Ornaments made from native copper have been found in the Ohio Valley, Arkansas and the Great Lakes region, but no gold or silver work.

2. Southwest Indian.—The famed Indian silverwork in the Southwest does not begin until 1853, when the craft was introduced to the Navaho by Mexican smiths. Although this Mexican origin is recognized by Arthur Woodward in his historical study of Navaho silversmithing (see *Bibliography*), he points out that certain ornament types and modes of decoration among the Navaho trace back to earlier Indian silverworking in the eastern woodland, the plains, and the Rocky Mountains. It was not until 1872 that the first Zuñi smith learned the craft from the Navaho. The Zuñi had been carving turquoise long before the introduction of silversmithing, so it is not surprising that the most prominent characteristic of Zuñi work is the extravagant use of turquoise

insets. Navaho work is distinguished by die-stamped designs, whereas die-work is very rare in Zuñi silver. Authentic Navaho and Zuñi pieces are still being made, but the tourist market has been flooded with cheap, commercial imitations.

3. **Colonial.**—Silversmithing in the New World in the colonial period is more or less derivative from Europe and England. In North America it was first brought to New England by English craftsmen in the 17th century. The most important centres were Boston, Newport, New York, Philadelphia, Baltimore and Annapolis. Outstanding collections include the Garvan Collection at Yale University, and those in the Boston Museum of Fine Arts, the American Wing of The Metropolitan Museum of Art in New York, and the Philadelphia Museum of Art. North American colonial silver is distinguished for its simplicity and graceful forms, copied or adapted from English silver of the period. On the other hand, the colonial silver of Mexico, Brazil, Colombia, Peru, Chile and Bolivia, while European in concept, shows a blending of Iberian designs and forms with indigenous influences that trace back to pre-Hispanic times. Most of these relics survive in churches as sacramental vessels, but there are some notable private collections such as that of Pedro de Osma and the collection of silver stirrups, spurs and horse trappings belonging to Constante Larco Hoyle, both in Lima, Peru.

4. **Modern.**—The outstanding centre for fine handwork in silver in the Western Hemisphere is the little village of Taxco in the state of Guerrero, Mexico. An American resident, William Spratling, revived the ancient craft there in 1931, and trained a whole generation of talented silversmiths. As of a census made in 1955 there were about 300 workshops, large and small, each dedicated to artistic handwork in silver. (D. T. E.)

IV. THE MIDDLE AND FAR EAST

1. **Iran.**—The Persians have been skilful metalworkers since the Achaemenid period (550–330 B.C.) when they were already acquainted with various techniques such as chasing, embossing, casting, and setting with precious stones. Statuettes of gold and silver are known from the 5th century B.C. and vessels of silver and gold from this time take the form of phials, conical cups, vases and rhyta (drinking cups in the shape of an animal's head). The Oxus treasure in the British Museum and the Susa find in the Louvre, Paris, are good examples of such work. During the Parthian period (247 B.C.–A.D. 224) silver and gold work was strongly influenced by Hellenistic predilection for richly decorated bowls and dishes. The zenith of old Iranian metalwork, however, was reached during the Sassanid period (A.D. 224–651) when there was great variety of shape, decoration and technique. Drinking vessels—stem cups and cups with handles—ewers, oval dishes, platters and bowls are the dominant forms; hunting scenes, drinking scenes and animals are represented in high relief. The patterns were cut out of the solid silver, or made separately in sheets and then soldered to the vessel. In some cases parts of the decoration are traced on a ringmatted ground and parcel gilt. From this time onward cloisonné enamel is used for jewelry.

During the Islamic period gold and silver were used either as an inlay on vessels of bronze, brass and iron or for jewelry. Earrings, bracelets and necklaces were often made in filigree work.

2. **India.**—In India gold jewelry has been found from the Indus culture. Excavations at Takshasila (Taxila) have revealed gold and silver drinking vessels and jewelry of Hellenistic types dating back to about the 1st century A.D. From the same time is the important Buddhist gold reliquary from Bimaran, Afg., set with rubies and decorated with *repoussé* figures in Gandhara style (*see* INDIAN ART); it is now in the British Museum, London.

During the Gupta period (A.D. 320–647), vessels of Hellenistic and Persian shapes were evidently made, for they are represented in the sculpture and frescoes of the period. More Indian in style are a silver dish of the 3rd or 4th century A.D., decorated with a Bacchanalian scene, and a silver bowl of the 7th century from northern India embellished with medallions in low relief (both in the British Museum). Jewelry played a very important role and can also be studied in the frescoes at Ajanta and on contemporary sculptures, though no original pieces have survived.

In spite of the fact that gold and silver vessels have been common in India since classical times there is very little material extant before the 17th century when all kinds of vessels were produced in bronze, brass, copper, and, for the royal houses, in silver. The shapes and decorations vary in the different regions. Delhi was famous for its craftsmen, especially in the time of Akbar the Great (1556–1605), Jahangir (1605–27) and Shah Jahan (1627–58). Much work was done in precious metal, and vessels and ornaments of jade were inlaid with gold and gems. Northern India is famous for its enamels. Enamelers from Lahore were brought to Jaipur in the 16th century by Man Singh, and enamel was employed extensively in combination with gold and silver work in the 17th and 18th centuries there and elsewhere. The Punjab, Lucknow, and the districts of Chanda, and Cutch in Gujarat State were long celebrated for their metalworkers. In the south the silver work in *svamin*-style is characterized by religious figure scenes in relief which were executed in three different techniques. Tirupathi put silver sheet on copper; Madras, Bangalore, and Tiruchirappalli are known for hammered vessels with traced decoration; and Thanjavur (Tanjore) produced a more Baroque effect with inlays of silver in copper. From the former Travancore state, Mysore and Bijapur in the southwest come chased vessels with floral patterns, the lotus being the dominant motif. In the north the Hindu style is well represented by works from Varanasi (Benares).

Persian-Islamic influence is found in several shapes of the vessels; *e.g.*, ewers and basins for water, and smoking furniture such as hookas also with Islamic patterns. Jewelry from the later periods employs precious stones, pearls, gold and silver in great variety. The old types are repeated with symmetrical arrangements of rosettes and leaves for bracelets, necklaces, pendants, rings and foot ornaments. Very fine work in silver filigree was executed at Cuttack in Orissa and was employed on jewelry and various larger items.

3. **Nepal, Tibet, Burma, Thailand, Annam.**—Indian styles and techniques spread to the neighbouring countries. In Nepal precious metals were used in architecture; pagodas, temples and palaces sometimes had facades richly decorated with ornaments embossed in gilt copper with settings of precious stones.

In Tibet copper and brass were usually used for vessels but these metals were often decorated with applied silver or gold ornaments, and in eastern Tibet especially teapots were made of silver with gilt appliqué. While many of the ornaments are Chinese, Buddhist shapes and patterns of Indian origin were used for ritual vessels. Other ritual objects were sometimes made of silver or, more rarely, of gold, though bronze is again the common material. Silver is used for the amulets and jewelry with rich setting of turquoises, carnelian and lapis lazuli.

In Thailand the Buddhist vessels were made out of chased silver very often in the shape of a lotus flower whose petals are decorated with other floral and figure motifs in *repoussé*.

Burma is known for its chased silver vessels heavily decorated with figures and floral patterns in relief, related to the south Indian *svamin* work. The use of gold and silver vessels for domestic purposes was denied to all but those of royal blood. Good examples of earlier golden regalia are in the Victoria and Albert Museum.

In Annam gold and silver work of the Cham culture is preserved from the 10th century, exemplified by the crown and heavy jewelry made for a life-size statue found in the ruin of a temple at Mi-son. From later times are the royal treasure with four crowns, various amulets, armrings, and table services of gold richly decorated with *repoussé* and open work.

4. **China.**—In ancient China gold and silver were rare. Gold was used as an inlay for bronzes in the Chou dynasty (1027–256 B.C.), and between the 6th and the 2nd centuries vessels and small bronzes for daily use were very often decorated with geometrical and zoomorphic patterns hammered into the bronze surface. Gilding and silvering are also common at the same period. Dresshooks and small items of jewelry were sometimes cast in gold and silver and imitated the more usual bronze forms. Granular work is used for jewelry, a technique which probably has an Indian origin.

Silverwork first became important during the T'ang period (A.D. 618–906) when the Chinese had learned from the Sassanid Persians how to chase the silver. To begin with they followed their teachers very closely in the forms of the bowls and larger vessels as well as in the patterns. The T'ang drinking vessels such as stem cups, cups with handles, ewers, trays, and lobed oval dishes on a stem are Persian shapes transformed by Chinese taste. Among the patterns are vine and palmette scrolls of great variety, hunting scenes and landscapes of symmetrical flowers and trees with birds and animals; all these have parallels in Persian silver and textiles but are more delicate in their Chinese version. The techniques used by the Sassanid silversmiths are adopted by the Chinese; for example, double sheets for a bowl and tracing of the patterns on ringmatted ground. T'ang jewelry is made of gold or gilt silver mainly as hair ornaments in granular work and filigree ornamented with set turquoises. Collections of T'ang silver and jewelry can be seen in the Shosoin Imperial Treasure House at Nara, Japan; in the Carl Kempe Collection, Stockholm; and in the British Museum and the Victoria and Albert Museum, London.

During the Sung dynasty (960–1279) silver work declined in technical quality but jewelry played a more dominant role. Hair ornaments became increasingly intricate with elaborate naturalistic flowers and various auspicious symbols.

During the Yüan (1280–1368) and Ming (1368–1644) periods skill in silver work revived and once again the smiths followed many Near Eastern styles. Drinking vessels (ewers and cups), boxes, and even large ceremonial gold vessels have been found in the Ming tombs. During the excavation of the tomb of Emperor Wan Li (1573–1620) in 1956–58 a series of gold vessels set with precious stones was found together with porcelain and textiles. All the gold items are decorated with incised patterns of dragons, phoenixes and similar subjects.

During the Ch'ing period (1644–1912) both silver and gold were used lavishly and gold filigree work especially is common in the 18th century. However, most of the forms and ornaments employed are borrowed from lacquer and porcelain ware and only jewelry has its own style, rich combinations of kingfisher feathers glued to the metal.

5. Korea.—The Chinese colonists who settled in Korea during the Han Empire (202 B.C.–A.D. 221) first brought gold- and silversmiths to Korea. By the 5th–6th centuries A.D. Korean work, as exemplified by large gold crowns and various pieces of jewelry excavated from tombs at Kyongju, was beginning to develop distinctive characteristics. At the time of the United Silla (668–935) and Koryo (918–1391) kingdoms Chinese influence was strong but the Korean style persisted in silver and gold work. Several vessels with floral patterns in relief are preserved from these periods.

6. Japan.—Knowledge of metalwork seems to have spread to Japan by way of Korea during the Yayoi Period (*c.* 1st century B.C.) but gold and silver never played any important role in this country. In the Nara period (A.D. 710–784) the Chinese T'ang style was dominant and most of the gold and silver work preserved in the Shosoin at Nara was made under Chinese influence or by Chinese workmen. Silver vessels were used extensively among the aristocracy in the Heian period (784–1185), although not many of these vessels have survived, and both gold and silver were often used for applied reliefs or as inlay on bronze. In the later periods the use of precious metals was practically confined to inlays in bronze or iron and the highest technical skill is shown by the artists who made the sword fittings. (B. V. Gy.)

SILVER CITY, a ghost town of Owyhee County in southwestern Idaho, U.S., was founded March 10, 1863, and quickly displaced adjacent Ruby City as the centre of the Owyhee mines. Exceptionally rich silver lodes in nearby War Eagle and Florida mountains took years to develop but were the subject of great excitement and bitter rivalry for control. The Poorman mine, although entangled in litigation, publicized the district particularly well; silver crystals from it won a special gold medal at the Paris Exposition of 1866. In 1868 armed conflict among claim owners forced the governor to dispatch troops from Ft. Boise to restore order. An important mining industry with a strong labour union movement had developed prior to financial collapse of the silver market accompanying the failure of the Bank of California on Aug. 26, 1875; by then Silver City had Idaho's earliest daily newspaper—the *Owyhee Daily Avalanche*—and sufficient stability to survive the economic panic. More efficient mining technology, extensive British investment, and improved railway transportation near that remote mountain district (elevation over 6,000 ft. [1,800 m.]) brought a long revival after 1886. The gradual decline of mining activity led to loss of population and, in 1935, of the county seat. Silver City's peak population had been several thousand; in the 1960s it was less than 50. It can be reached by road from Nampa (44 mi., part paved) or by gravel road (about 20 mi.) from the highway between Boise and Reno, Nev. There are a number of other ghost towns in the county. *See* also IDAHO: *History*. (M. D. B.)

SILVERFISH, a slender, flat, wingless insect, *Lepisma saccharina*, with three tail bristles, so called because of its covering of silvery scales, flexible body, and quick movements. It normally lives indoors and is worldwide in distribution. Like many domestic insects, its original habitat is unknown; its nearest wild relatives are in Africa and western Asia. Occasionally, it damages paper and fabrics by eating the farinaceous sizing and glue; usually, it does little or no damage, unlike its similar-looking relative, the firebrat (*Thermobia domestica*).

The silverfish belongs to the family Lepismatidae of the order of bristletails (Thysanura) and is in the primitive subclass Apterygota (*q.v.*), none of whose members was ever winged. It is plain gray with the antennae and tail bristles shorter than the body. Four common species of domestic Lepismatidae are mistaken for the silverfish: the firebrat has conspicuous dark brown and cream markings; *Ctenolepisma longicaudata*, like the silverfish, is plain gray but has antennae much longer than the body; *Ctenolepisma lineata*, also with long antennae, has dark longitudinal stripes on the gray background; and *Acrotelsa* (*Stylifera*) *gigantea* is evenly dark in colour and lives only in warm regions.

The males superficially resemble the females. Unlike all other groups of true insects, the silverfish and its closest relatives have, instead of actual copulation, courtship movements with the male depositing a packet of sperm that the female then places in her vagina. The oval, whitish eggs probably are inserted into cracks and litter. The young, which hatch in several days, are scaleless and have short appendages; they molt every few days and gradually acquire the adult characters.

The silverfish, unlike most insects, continues to molt throughout the two or more years of its life, long after reaching sexual maturity. Control can be accomplished with poisonous baits or insecticides. *See* also INSECT; ENTOMOLOGY: *Principles of Insect Control*. (C. L. RE.)

SILVERIUS, SAINT (d. 537), pope from 536 to 537, was a legitimate son of Pope Hormisdas, born before his father entered the priesthood. He was consecrated successor to Agapetus I on June 8, 536, having been pressed on the Roman clergy by the Ostrogothic king Theodahad. Six months afterward (December 9) he was one of those who admitted Belisarius' Byzantine forces into the city.

Silverius opposed the restoration of the patriarch Anthimus, whom Agapetus had deposed, and thus brought upon himself the hatred of Theodora, who desired to see Vigilius made pope. He was deposed by Belisarius in March 537 on a charge of treasonable correspondence with the Goths, degraded to the rank of monk and sent to Lycia. Justinian, who entertained his complaint, sent him back to Rome, but Vigilius was ultimately able to banish his rival to the island of Palmarola, off Naples, where he died, probably about December 537. He is venerated as a martyr; feast day June 20. *See* also PAPACY.

SILVER SPRINGS, one of the largest limestone springs in the world, is in Marion County, Fla., U.S., 6 mi. E of Ocala. The average flow of the springs is about 530,000,000 gal. per day and more than 480 tons of minerals are carried off in solution each 24 hours. The water maintains a constant temperature of 72° F (22° C). The source of the main spring is a cavern 65 ft. long and 12 ft. high. Most of the water discharged from the more than 100 springs in the group is from the abundant rainfall of north-central Florida, which passes through the porous surface soil and sand of the region and enters the limestone lying immediately beneath. This filtration causes the extreme clearness of the spring water.

Silver Springs is the source of Silver River, a 7-mi.-long navigable stream which eventually reaches the Atlantic Ocean via the Oklawaha and St. Johns rivers. There are more than 30 varieties of fish, as well as turtles and shellfish in Silver Springs. Remains of mastodons, manatees, and extinct elephants have also been found in the springs or in the Silver River.

Swimming facilities, glass-bottomed boat rides, cruises on the Silver River, a zoo, and a snake farm are provided for visitors. Thousands of tourists visit the springs each year. Because of the clarity of the water, Silver Springs is a favourite location for motion-picture companies that wish to film underwater scenes.

The explorer Hernando de Soto was probably the first European to see Silver Springs when he camped at Ocali, an Indian village near the springs, in 1539. The Indian name for Silver Springs is Sua-ille-oka, which means "sun-glinting water." (J. E. Jo.)

SILVESTER (SYLVESTER), the name of three popes and an antipope.

SAINT SILVESTER I (d. 335), pope from 314 to 335, succeeded Melchiades. The most important event of his pontificate was the Council of Nicaea (325), which condemned Arius. Silvester did not attend personally but was represented by two legates. Associated with his name is the famous legend (which developed after his own time) according to which he is supposed to have baptized the emperor Constantine I in the Lateran and cured him of leprosy. Supposedly, it was gratitude for this that caused Constantine to give him dominion over the four Eastern patriarchates and over almost all the Western world, the so-called Donation of Constantine. This legendary gift, which since the early 16th century has been acknowledged by many scholars to be a forgery, was of importance in the development of the medieval theory of church and state (*see* DONATION OF CONSTANTINE). Silvester's feast day is Dec. 31. (R. E. McN.)

SILVESTER II (Gerbert) (d. 1003), pope from 999 to 1003, was born in the county of Auvergne. Educated in the abbey of St. Géraud at Aurillac in Auvergne under the abbots Gerald and Raymond, he was taken beyond the Pyrenees in 967 by Borel, count of Barcelona, who entrusted his further education to Atto, bishop of Vich (Ausona). Accompanying these two patrons to Rome in 970–971, Gerbert was presented to the emperor Otto I, to whom he admitted his skill in the quadrivium (*i.e.*, the medieval liberal arts of arithmetic, music, geometry and astronomy) while deploring his comparative ignorance of logic. About 972 he went to Reims to study under Archbishop Adalbero, under whom he seems to have lectured for many years, having among his pupils Robert, the future king of France, and the chronicler Richer. His growing fame roused the envy of Otric of Saxony, who, suspecting him of error in his classification of the sciences, accused him of this before the emperor Otto II. By Otto's command the two rivals then had a disputation at Ravenna, which is said to have lasted a whole day (about Christmas, 980). Otto subsequently gave Gerbert the abbey of Bobbio (982 or early 983), but Gerbert found such difficulty in collecting his dues that he returned to Reims in 984 to resume

service under Adalbero. The latter involved him in his intrigues against the last Carolingian kings of France.

Adalbero died in Jan. 989, having, according to Gerbert, designated him his successor as archbishop. The appointment, however, was given instead to Arnulf, an illegitimate son of the late king Lothair. Arnulf took an oath of fealty to Hugh Capet, who had taken the place of Lothair's son Louis V as king of France, and Gerbert was persuaded to remain with him. Then, in the late summer or autumn of 989, Reims was taken by Lothair's brother Charles of Lorraine, now the head of the Carolingian house. Gerbert, falling into Charles's hands, continued for a time to serve under Arnulf, who had gone over to his uncle's side. He was able, however, to return to the Capetian allegiance before the treachery of Adalberon (Ascelin) of Laon put both Charles and Arnulf at the mercy of Hugh Capet (March 991). At the synod of St. Basle, near Reims, Arnulf was degraded from the archbishopric and Gerbert, in recognition of his services, appointed his successor (June 991).

The vigour and the activity of Gerbert as a metropolitan made themselves felt as far away as Tours, Orléans and Paris. But meanwhile Arnulf's friends were active, and Pope John XV objected to the summary deposition of Arnulf. Gerbert had to appear before a papal legate at Mouzon in 995 and went himself to Rome to put his case before the new pope, Gregory V, in 996 (he was present at Otto III's coronation). Finally, in 997, after Gregory's synod of Pavia had suspended all the bishops concerned in the proceedings of St. Basle, Gerbert despaired of his archbishopric and left France for the court of his former pupil the young emperor Otto III.

Otto welcomed him as an old supporter of the imperial family as well as a great scholar and quickly procured his appointment to the archbishopric of Ravenna (about April 998). The death of Gregory V during the following year enabled the emperor to do even better for his protégé, by sponsoring his elevation to the papacy. Gerbert was consecrated as Silvester II on April 2, 999. It is he who is generally credited with having encouraged the splendid vision of a restored empire that then began to fill Otto's mind.

In ecclesiastical administration Silvester was by no means inactive. He confirmed his old rival Arnulf in the see of Reims (999), rebuked Adalberon (Ascelin) of Laon for his crimes (1000), and settled the dispute between Willigis, archbishop of Mainz, and Bernward, bishop of Hildesheim (1001). Of more lasting importance was the erection of Gniezno to metropolitan status in a Polish church independent of the German hierarchy (1000). The genuineness of the letter to St. Stephen of Hungary, accepting his kingdom as a fief of the Holy See, is contested. Silvester's plans for the advancement of the church and empire together were halted by Otto III's death on Jan. 23, 1002. Little more than a year later, on May 12, 1003, the pope himself died. He was buried in the church of St. John Lateran.

Besides being the most distinguished statesman, Gerbert was also the most accomplished scholar of his age. Richer has left a detailed account of his system of teaching at Reims. So far as the trivium (grammar, rhetoric and logic) is concerned, his textbooks were Victorinus' translation of Porphyry's *Isagoge,* Aristotle's *Categories* and Cicero's *Topics* with the commentaries of Boëthius. From dialectics he urged his pupils to the study of rhetoric; but, recognizing the necessity of a large vocabulary, he accustomed them to read Virgil, Statius, Terence, Juvenal, Horace, Persius and Lucan. More remarkable still were his methods of teaching the quadrivium. To assist his lectures on astronomy he constructed elaborate globes of the terrestrial and celestial spheres, on which the course of the planets was marked. For facilitating arithmetical and perhaps geometrical processes he constructed an abacus with 27 divisions and a thousand counters of horn. A younger contemporary speaks of his having made a wonderful clock or sundial at Magdeburg. It is known from his letters that Gerbert was accustomed to exchange his globes for manuscripts of those classical authors that his own library did not contain.

More extraordinary still was his knowledge of music—an accomplishment which seems to have been his earliest recommendation to Otto I. Gerbert's letters contain more than one allusion to organs which he seems to have constructed, and William of Malmesbury preserved an account of a wonderful musical instrument still to be seen in his days at Reims. The same historian says that Gerbert borrowed from the Saracens the abacus with ciphers (namely, for numerals from one to nine, instead of mere units, but without the zero).

Perhaps Gerbert's chief claim to the remembrance of posterity is to be found in the care and expense with which he gathered together manuscripts of the classical writers. His love for literature was a passion. In the turmoil of his later life he looked back with regret to his student days, and "for all his troubles philosophy was his only cure." Everywhere (Rome, Trier, Montier-en-Der, Gerona, and Barcelona) he had friends or agents to procure copies of the great Latin writers for Bobbio or for Reims. To the abbot of Tours he writes that he is "labouring assiduously to form a library," and "throughout Italy, Germany and Lorraine [Belgica] is spending vast sums of money in the acquisition of mss." It is noteworthy, however, that Gerbert never wrote for a copy of one of the Christian fathers, his aim being, seemingly, to preserve the fragments of a fast-perishing secular Latin literature.

So remarkable a character as that of Gerbert left its mark on the age, and fables not unlike those later accumulated around Faust soon began to cluster round his name. Toward the end of the 11th century Cardinal Benno, the opponent of Hildebrand, is said to have made Gerbert the first of a long line of magician popes. William of Malmesbury adds a love adventure at Córdoba, a compact with the devil, the story of a speaking statue that foretold Gerbert's death at Jerusalem—a prophecy fulfilled, somewhat as in the case of Henry IV of England, by his dying in the Jerusalem church of Rome—and that imaginative story of the statue with the legend "Strike here" which found its way into the *Gesta Romanorum.*

Collections of Gerbert's works were edited by A. Olleris, *Oeuvres de Gerbert, pape sous le nom de Sylvestre II* (1867); by J. Havet, *Lettres de Gerbert* (1889); and by N. Boubnov, *Gerberti opera mathematica* (1899).

Silvester III (John), bishop of Sabina, became pope on Jan. 20, 1045, after the Romans had driven out Benedict IX; but he resigned the papacy on March 10, 1045. Retiring to his old bishopric, he recognized Gregory VI as pope. The synod of Sutri (Dec. 1046), under the presidency of the emperor Henry III, formally passed sentence of deposition on him, as is shown by the documents issued in his capacity as bishop of Sabina during 1046.

Silvester IV (Maginulf), antipope from 1105 to 1111, a man of dubious antecedents, was elected in opposition to Paschal II by the dissident nobles under Werner, margrave of Ancona, on Nov. 18, 1105. Though Paschal's troops expelled him from Rome the next day, his supporters continued to give trouble during the following year; and the emperor Henry V accorded him some recognition. When Paschal and Henry came to terms, however, the antipope's pretensions were dismissed (April 1111).

See also Papacy.

SILVICULTURE is the technical branch of forestry (*see* Forests and Forestry) which is concerned with the establishment and maintenance of the forest. *See* Arboriculture.

SIMANCAS, a town of northern Spain in Valladolid Province, on the right bank of the Pisuerga River and 8 mi. (13 km.) SW of Valladolid on the road to Zamora. Pop. (1960) 1,582 (mun. It was the Roman Septimanca and has a citadel dating from the Moorish occupation in the 9th century. In 939 it was the scene of a battle between the Moors and Christians. The citadel is now the Archivo General del Reino, to which the national archives of Spain were removed by order of Philip II in 1563. Their transfer to Simancas was said to have been first suggested by his secretary Francisco de los Cobos (d. 1547), who was the governor of this fortress. The extensive alterations were made by several celebrated

16th-century architects including Juan de Herrera. The arrangement of the papers was entrusted by the king to the archivist Diego de Ayala in 1561. They contain important private as well as state documents. The archives of the Indies were transferred in 1785 to the Lonja of Seville. (C. D. L.)

SIMBIRSK: *see* UL'YANOVSK.

SIMCOE, JOHN GRAVES (1752–1806), British soldier and first lieutenant governor of Upper Canada (1791–96), was born at Cotterstock, Northamptonshire, Eng., on Feb. 25, 1752. As commander of a Loyalist corps, the Queen's Rangers, he served with distinction during the American Revolution.

Appointed lieutenant governor of the newly established Upper Canada (later Ontario) in 1791, he proved an energetic administrator, although seldom moderate in his language about the United States. His enthusiasm for the new Canadian colony and for aristocratic government in it quickly waned, the more so as he greatly disliked the governor in chief, Lord Dorchester. In 1796 he agreed to go as governor and commander in chief to Saint-Domingue (Haiti), half-conquered by the British from the French. In seven months he reformed its administration and waged a successful campaign, but returned to England and resigned his colonial appointments. He was unable to get more active service, but was given command of the Western District with headquarters in Exeter (1799–1806). Then a new British government appointed him commander in chief in India; diverted on a diplomatic mission to Lisbon, Portugal, he fell ill and, returning to England, died at Exeter on Oct. 26, 1806.

SIMEON, SAINT, STYLITES (*c.* 390–459), Syrian monk, the originator of a fearful form of asceticism that consisted of standing ceaselessly, day and night, on top of a column (*see* STYLITE). Born near the border of Syria and Cilicia, and at first a shepherd, he spent several years in a monastery near Antioch, then remained three years walled up in a cell before he began to live in the middle of a circular enclosure. There his incredible austerity and the fame of his miracles attracted crowds of pilgrims. To escape from them he built taller and taller columns on which he could lead in peace a life of contemplation. His tallest column, on which he spent more than 20 years, was about 50 ft. high, railed round on top. He spent most of the day and night in prayer, with frequent deep obeisances. He ate practically nothing, and stood all the time, without any shelter from the sun, the cold, the wind, and the rain. Always exposed to public gaze, he seemed a superhuman example of spiritual strength, of penitence, and of closeness to God. Twice a day he preached to the people and concerned himself with their affairs, consoling the sick and miserable, and settling quarrels. He also converted pagans, of whom large numbers, especially Arabs, joined the Christian pilgrims who came to him from all parts of Syria and neighbouring countries and even from the West. The Greeks keep his feast on July 26, the date of his death, and principally on Sept. 1, when he was buried in Antioch.

BIBLIOGRAPHY.—H. Lietzmann, *Das Leben des hl. Simeon Stylites* (1908), including the three chief sources, with critical studies: Theodoret's *Historia religiosa* 26, the Greek life by the monk Anthony (with Lat. trans.) and a German trans. of the Syriac life; French trans. of Theodoret and Anthony, with rehabilitation of the latter, in A. J. Festugière, *Antioche païenne et chrétienne*, pp. 347–401 and 493–506 (1959). *See* also H. Delehaye, *Les Saints stylites* (1923); P. Peeters, *Orient et Byzance: Le tréfonds oriental de l'hagiographie byzantine*, pp. 93–136 (1950). (F. HA.)

SIMEON, SAINT, THE NEW THEOLOGIAN (949–1022), Byzantine abbot and mystic whose works had a formative influence on Orthodox spirituality, was born in Paphlagonia, of an aristocratic family, and came to Constantinople as a young boy. He insisted on entering the monastery of Studios (977), but differences with the abbot resulted in his migration to the neighbouring house of St. Mamas in the same year. There he became abbot (980) and imposed strict discipline. His vigorous cult of his spiritual father, Simeon the Studite, and other reasons brought him into conflict with the patriarch and he was exiled to the Asian shore of the Bosporus (1009). There he built up the monastery of St. Marina near Chrysopolis (Scutari) and, though eventually reconciled to the patriarch, refused to return to the capital. He was a well-known and popular figure and was called the Younger or the New Theologian, perhaps to distinguish him from the two other "theologians" par excellence in the Orthodox Church—John the Evangelist and Gregory of Nazianzus. Some of his works have been translated into modern Greek, Russian, and Latin; much has not been published in the original Greek.

His numerous writings fall into three main groups: sermons, the *capita*, and the "hymns of the divine loves." One group of the sermons, the catecheses, originally preached to the monks of St. Mamas, were later drastically revised and combined with other writings of Simeon to provide a compilation suitable for a wider public. Both his sermons and his hymns are illuminated by his own personal experience, and his underlying theme is the means, particularly obedience and tears, whereby through grace union with God may be attained in this life. His emphasis was often Christo-centric, though the climax of his mystical experiences was the indwelling of the Trinity revealed as divine light. His contribution is highly individual; he provides a link between earlier mystics, as John Climacus, and later Byzantine spirituality.

BIBLIOGRAPHY.—Hymns published by Dionysios Zagoraios with modern Gr. trans. of selected works, 2nd ed. (1886); critical ed. of *Capita* with Fr. trans. by J. Darrouzès (1957); critical ed. of catecheses with Fr. trans. by B. Krivocheine (1961); some works, mostly in Lat. trans. only, in J. P. Migne, *Patrologia Graeca*, vol. 120 (1864); Eng. trans. of hymns by J. M. Hussey (1961). For list of all works, with discussion of manuscript tradition, *see* B. Krivocheine, "The Writings of St. Symeon the New Theologian," *Orientalia Christiana periodica*, vol. 2, pp. 298–328 (1954). *See* also life by Simeon's disciple Nicetas Stethatus, ed. by I. SIMEON (SYMEON) OF DURHAM (d. *c.* 1130), English chronicler, author of the *Historia Dunelmensis ecclesiae* and probably author of part of the *Historia regum*, was a monk at Durham.

The *Historia Dunelmensis ecclesiae* is a useful history of the see of Durham from its establishment (635) at Lindisfarne (*see* HOLY ISLAND) to 1096. The *Historia regum* consists of two overlapping English histories, covering the years 731–957 and 848–1129 respectively. It was long attributed to Simeon, but it now seems certain that he had no part in compiling the first history, which contains unique and valuable Northumbrian annals for the 8th and 10th centuries. He was, however, probably responsible for the second history, a chronicle for the years 848–1118 based on Asser and Florence of Worcester, and a narrative of the years 1119–29, partly following Edmer but partly original.

BIBLIOGRAPHY.—Both works are in *Symeonis monachi opera omnia*, ed. by T. Arnold, 2 vol. (1882–85); for a translation, *see* J. Stevenson, *Church Historians of England*, vol. ii, part ii (1855). *See* also H. S. Offler, *Medieval Historians of Durham* (1958); P. H. Blair, "Some Observations on the 'Historia Regum' Attributed to Symeon of Durham," *Celt and Saxon*, ed. by N. K. Chadwick (1963).

SIMEON, CHARLES (1759–1836), Anglican churchman, a leader of the evangelical party and a representative of the evangelical tradition at its best, whose influence left an indelible mark on religious life at Cambridge, was born at Reading on Sept. 24, 1759, and educated at Eton and King's College, Cambridge, where he was a fellow from 1782 (vice-provost, 1790–92). He came under the influence of Henry and John Venn and in 1782 was presented to the living of Trinity Church, Cambridge, where he remained until his death. He was at first unpopular with his parishioners who had wanted the curate, John Hammond, in his place and his services were noisily interrupted. But his pastoral care, especially in sickness and in the famine of 1788, and his quiet, peaceable nature slowly won the regard of the town and the university, and he became widely known as an evangelical leader who was yet a convinced member of the Church of England and lover of its liturgy and discipline.

He was concerned for missionary work, especially in India, and persuaded his best pupils to the venture, above all his curate. Henry Martyn; he helped to found the Church Missionary Society (1799) and assisted the newly founded (1804) British and Foreign Bible Society and the Society for Promoting Christianity Among the Jews; he gave to the support of missions from his own pocket, including part of the payment for his *Horae Homileticae*, discourses on the Bible published in 21 vol. in 1832–33. Following the example of Henry Thornton, in order to ensure the continuity of evangelical teaching, he administered the Simeon Trust (founded 1816) to purchase the right to appoint clergymen to livings. He died on Nov. 13, 1836, and is buried in the chapel of King's College.

Smyth, *Simeon and Church Order* (1940); *Charles Simeon (1759–1836)*, ed. by A. Pollard and M. Hennell (1959). (W. O. C.)

SIMEON, in the Old Testament, a tribe of Israel, named after the second son of Jacob by Leah (Gen. 29:33). According to Gen. 34, the brothers Simeon and Levi massacred the males of Shechem to avenge the violation of their sister Dinah ("judgment") by Shechem the son of Hamor. Jacob disavowed the act, and on his deathbed solemnly cursed their ferocity, condemning the two to be divided in Jacob and scattered in Israel (49:5–7). Subsequently the priestly Levites (*q.v.*) are found distributed throughout Israel without portion or inheritance (Deut. 18:1, Josh. 13:14). Simeon, however, is assigned a territory—in the north, according to II Chron. 15:9, 34:6, but in southern Palestine according to Josh. 19:1–9, its cities being otherwise ascribed to Judah. Simeon is not mentioned in the "blessing of Moses" (Deut. 33), in the stories of the "judges," or in the earlier books of Samuel and Kings. It is conjectured that Dinah represents a clan or group that settled in Shechem and was exposed to danger (*e.g.*, oppression or absorption); the tribes Simeon and Levi intervened on its behalf, the ensuing massacre was avenged by the Canaanites and the two were broken up. These events are supposed to belong to an early stage in the invasion of Palestine by the Israelites (15th–13th century B.C.). (*See* TWELVE TRIBES OF ISRAEL.)

"Simeon" occurs in the New Testament, as the name of the seer who recognized the infant Jesus as the Redeemer (Luke 2:25–35) and as an alternate form of Simon.

SIMEON BEN YOHAI (2nd century A.D.), Galilean rabbinic teacher (*tanna*), one of the most eminent disciples of Akiba ben Joseph (*q.v.*) and the author, or editor, of the *Sifre*, a halakic midrash on Numbers and Deuteronomy, and of a midrash on Exodus, *Mekilta di Rab Shimeon ben Yohai* (*see* MIDRASH). The latter work, used by Maimonides, was lost for centuries and was not rediscovered and printed till the 20th century. Simeon's most eminent pupil was the patriarch Judah ha-Nasi, editor of the *Mishna*. Little is known of Simeon's life, but he became the focus of a cycle of legends centring about his concealment in a cave for 13 years, when he was pursued by Roman authorities. He advocated the ascetic ideal of total devotion to Torah learning. Later talmudic authorities concluded that "many tried to follow the ways of Simeon, but they did not succeed" (*Berachoth* 35b).

In the development of Jewish Law, Simeon stressed the importance of seeking "the reasons of the verses"—*i.e.*, the social purpose of the Torah (*Baba Metsia* 115a). He followed this rationalist procedure in ritual as well as in civil matters—for example, in exempting Ammonite and Moabite women from the prohibition "to enter into the assembly of the Lord" (Deut. 23:4–5 [3–4]; *Yebamoth* 77a, *Sifre* 249), since clearly the women could not be blamed for the inhospitality that had occasioned the prohibition.

Possibly because of Simeon's reputation as a miracle worker and an ascetic, the classic work of Cabala, the *Zohar* (13th century), was attributed to him. All modern scholars except the Orthodox are agreed that the *Zohar* was the work of Moses de León (*see* CABALA). Simeon's grave at Meron, near Safad in Galilee, became a shrine for the *Hasidim* and Oriental Jews, and even today *Lag Beomer* (33rd day after the second day of Passover), the traditional anniversary of his death, is observed as a festive day of remembrance, with thousands participating in the burning of garments and other ceremonies at the grave.

For Simeon's *Mekilta*, *see* M. M. Kasher (ed.), *Horambam Vehamechilta* (1943); for the school of Akiba, *see* A. J. Heschel, *Torah min Hashomayim* (1964). (J. B. A.)

SIMEON METAPHRASTES (also surnamed LOGOTHETE and MAGISTROS) (second half of 10th century A.D.) was the most famous Byzantine hagiographer. His *Menologion* in ten volumes contains 148 lives of saints, arranged according to their feast days from Sept. 1 to Aug. 29. Most of these texts had existed previously but were not well written; Simeon gave them a stylistic revision (Gr. *metaphrasis*). This new *Menologion* was so popular that older collections ceased almost entirely to be copied; hence the disappearance of so many pre-metaphrastean lives. Simeon also wrote letters, religious poetry, and a universal chronicle which raises particularly complicated problems of textual criticism. His feast day is Nov. 28 in the Greek Church.

Beck, *Kirche und theologische Literatur im byzantinischen Reich*, pp. 570–575 (1959). For the chronicle *see* G. Moravcsik, *Byzantinoturcica*, 2nd ed., vol. 1, pp. 515–518 (1958). (F. HA.)

SIMEULUE, the northernmost island of the chain off the west coast of Sumatra, Indonesia, and administratively part of Atjeh (*q.v.*) province. Pop. (1960 est.) 25,000. The island, about 61 mi. (98 km.) long, is hilly, the coasts being rocky and reefbound. Sinabang, on a bay in the southeast, is the capital and port, from where there is irregular connection with Tapaktuan on the Sumatran mainland. There is also a cable between Simeulue and Singkil, in Atjeh. Other small places on the coast are Sibigo, Laehobang, Lassihing, and Urung. The Banjak islands, 67 in all, lie southeast of Simeulue; they are prolific in coconut palm and are a source of copra. The inhabitants of the island were formerly a prey of the Achinese (*q.v.*, Atjehnese) slave traders. (J. O. M. B.)

SIMFEROPOL, a town and the administrative centre of the Krymskaya (Crimea) Oblast' of the Ukrainian Soviet Socialist Republic, U.S.S.R., stands on the left bank of the Salgir River, where it emerges from the Crimean Mountains. Pop. (1959) 186,167. Although there has been settlement on the site since ancient times, the modern town of Simferopol was founded by the Russians in 1784, adjacent to the Tatar town of Ak-Mechet, after the annexation of the Crimea. There are large engineering industries producing machine tools and equipment for chemical and food-processing factories, power stations, and railways. Tinned foods, jam, wine, tobacco and cigarettes, perfume, and knitwear are also produced. Simferopol's many educational and cultural institutions include agricultural, medical, and pedagogic institutes, a research institute of mineral resources, a picture gallery, and three theatres. (R. A. F)

SIMILAR FIGURES in geometry have the same shape but not necessarily the same size; *e.g.*, any two squares are similar: if they are of the same size, they are also congruent, or identically equal. Any two circles are similar, but not any two ellipses, for ellipses may have different shapes (*see* ELLIPSE). Solids may also be similar, as in the case of cubes or of spheres. Similarity of figures is the basis of trigonometry (*q.v.*) and of indirect measures in general. Speaking more precisely, two systems of points $A_1, B_1, C_1, \ldots$ and $A_2, B_2, C_2, \ldots$, are said to be similar when they can be so placed that all lines $A_1A_2, B_1B_2, C_1C_2, \ldots$ joining corresponding points form a pencil whose vertex O divides each line into segments having a constant ratio r. In the figure that is shown here, the constant ratio is 2/3. Two figures are said to be similar when their systems of points are similar. The point O is called the centre of similitude. If $r = 1$, the figures are said to be symmetric with respect to the centre O.

SIMLA, a town and district in the Ambala division, and the headquarters of the union territory of Himachal Pradesh, India. Town pop. (1961) 42,597. Simla, a cosmopolitan town and one of the most popular hill stations in India, lies 175 mi. (282 km.) N of Delhi, with which it is linked by both road and rail. It occupies a ridge of the lower Himalayas, running east and west for about 6 mi. (10 km.). The ridge culminates in the east in the summit of Jakko (8,053 ft. [2,455 m.]) and in the west in the Observatory Hill (7,050 ft. [2,149 m.]). To the north a beautiful wooded spur, known as Elysium, branches from the main ridge. The pattern of the settled area, which extends from 6,500 to 8,000 ft. (2,000 to 2,500 m.) above sea level, is like an irregular crescent. The higher parts are occupied by wealthy families, who live in villas and bungalows around Kaithu, Elysium, Jakko, and the central belt. On Observatory Hill stands the President's Lodge, formerly the summer residence of the British viceroy. The focal point of the town is beneath Jakko. There are the main libraries, cinemas, hotels, the town hall, and Christ Church. The main road and the only real shopping centre is the Mall, which runs from end to end of the town just beneath the ridge. Below the eastern part of the Mall is the tin-roofed Bazaar, a densely built area, with houses clinging to a steep slope, which is approached by a road at each end, and is otherwise accessible only by means of steps and tortuous alleys.

Near the railway station, in the southwest, are military and government offices, and three miles to the west is the cantonment of Jutogh. Besides several sanatoria the town has two undergraduate colleges and a women's training college attached to Panjab University. Simla has splendid scenery with steep valleys on either side, thickly forested with deodar; rhododendrons clothe the slopes up to the limit of perpetual snow. To the north is the network of the Himalayan ranges rising one above the other, with snow-covered crests in the distant north. To the south are the Kasauli and Sabathu hills. The town has a mean temperature of 4° C (39° F) in January and 19.5° C (67° F) in July. Average annual rainfall (most of it in July and August) is 63 in. (1,600 mm.). Snow often falls in winter.

Simla was used as a rest area for troops after the Gurkha War, 1814–16. The first English house was built there in 1819. The governor general, Lord Amherst, spent a part of the summer in Simla in 1827 and after that it began to grow in popularity as a health resort, government departments, commercial firms, the army, and tourists making increasing use of it. From 1865 to 1939 Simla was the summer capital of the government of India. The British set the fashion of a definite seasonal migration to this hill station to escape the summer heat of the plain, and wealthy Indians followed their lead. After the outbreak of World War II, the essential government departments remained in Delhi and those of lesser importance in Simla. From 1947 until 1953 Simla was the headquarters of the East Punjab Government, subsequently becoming the headquarters of the government of Himachal Pradesh.

SIMLA DISTRICT, the smallest district of the former Punjab, has an area of 254 sq.mi. (658 sq.km.) and a population (1961) of 112,653. (O. P. B.)

SIMMEL, GEORG (1858–1918), German philosopher and sociologist whose fame as an original scholar rests on several lengthy and brilliantly written essays on sociological methodology and analysis, although during the last decade of his life he devoted himself mainly to metaphysics and aesthetics. He became well known to U.S. sociologists, in part because of the translations and commentaries on his works by A. W. Small, one of the important early sociologists.

Simmel was born in Berlin, March 1, 1858, and was appointed a lecturer in philosophy at Berlin University in 1885, where he remained until called to the chair of philosophy at Strasbourg University in 1914. He died there on Sept. 28, 1918. Simmel is noted for his analytical study of the forms of social interaction. He sought to isolate the general forms or recurrent regularities of social interaction from the specific content of association in concrete types of activity, such as political, economic, and aesthetic. Hence, his sociological writings were abstract rather than realistically descriptive of life.

In his studies of social interaction Simmel gave special attention to the problem of authority and obedience. His methodological contributions did much to clarify the scope of sociology, to give it greater precision, and to establish it as a basic social science in Germany. Simmel made one important effort to apply his abstract principles to the interpretation of social behaviour in a specific field, economics, in his essay *The Philosophy of Money.* He stressed the role of a money economy in specializing social activity and depersonalizing individual and social relationships, a concept later developed more fully by Werner Sombart in his famous work on capitalism. Simmel's writings on the philosophy of history, ethics, religion, and art are also important.

See Rudolf Heberle, "The Sociology of Georg Simmel," ch. xi, in H. E. Barnes *et al., An Introduction to the History of Sociology* (1948). (H. E. BAR.)

SIMMS, WILLIAM GILMORE (1806–1870), U.S. regional novelist, was born in Charleston, S.C., April 17, 1806.

Edgar Allen Poe stated in 1844 that Simms had "more vigor, more imagination, more movement and more general capacity than all our novelists (save Cooper) combined." A 20th-century critic, J. B. Hubbell, stated that Simms "rather than Poe is the central figure of the literature of the Old South. He knew personally most of the southern writers of the time, and he more than any other man stimulated them to write and to publish. But he was a national as well as a sectional figure, and he was the most important literary link between North and South." (J. B. Hubbell, *The South in American Literature*, p. 572, Duke University Press, 1954.) Of Simms' 82 volumes, his historical novels are most important. His field of fiction is the frontier of the lower South—Spanish explorations of the 16th century, the settlement of South Carolina in the 17th, the revolution in South Carolina in the 18th, and southwestward migration in the 19th, preserving for the social historian an authentic and salty cast of woodsmen, Indians, Negro slaves, partisan fighters, outlaws, adventurers, loyalists, shyster lawyers, land speculators, gamblers, half-breeds, and typical ladies and gentlemen of what to Simms was a heroic age.

Motherless at two, Simms was reared by his grandmother, while his Scotch-Irish father fought in the Creek wars and under Jackson at New Orleans. Simms lived a vicariously adventurous childhood through his father, while absorbing history through his storytelling grandmother who had lived through the Revolution. He attended public schools four years. Upon entering the College of Charleston at the age of ten he knew enough French, Latin, German, and Spanish to dabble in translations. At the age of 12 he completed the study of materia medica, and leaving college became a druggist's apprentice. He began publishing poetry in Charleston papers at 16, edited a magazine and published a volume of poetry at 19, married at 20, and was admitted to the bar at 21.

Simms was a prodigious worker, whether at Woodlands Plantation in winter, Charleston in summer, or on yearly publishing trips north. As state legislator and magazine and newspaper editor (the *Charleston City Gazette*), he became embroiled in political and literary quarrels. From Charleston and the South he nevertheless received lifelong praise approaching adulation; from the North, wide audience and eminent literary friendships. Though he was shadowed by the defeat of the Confederacy, the death of his second wife, poverty, and the destruction of his home and library by Gen. William T. Sherman's stragglers, the five volumes of his published letters attest a gallant figure, the richness of whose performance was too long underestimated by literary historians. He died on June 11, 1870, in Charleston.

Simms' chief fault was writing too much, too carelessly, and with too frequent use of stock devices; he was at his best the master of a racy and masculine English prose style. His gift as a charming teller of tales in the oral tradition, and the care of an antiquarian in preparing historical materials, triumph over hasty composition, whether in *Vasconselos* (1853) in a 16th-century setting; *The Yemassee* (1835) in a colonial setting; his revolutionary series—*The Partisan* (1835), *Mellichampe* (1836), *The Kinsmen* (1841), *Katherine Walton* (1851), *Woodcraft* (1854), *The Forayers* (1855), *Eutaw* (1856); the best of his border romances—*Richard Hurdis* (1838) and *Border Beagles* (1840); his

short story collection *The Wigwam and the Cabin* (1845); or in his *History of South Carolina* (1840). Of his 19 volumes of poetry the collected *Poems* (1853) deserve mention. Most popular of his biographies were *The Life of Francis Marion* (1844) and *The Life of Chevalier Bayard* (1847). His literary criticism is represented in *Views and Reviews of American Literature* (1845).

See A. S. Salley and Donald Davidson (eds.), *Letters of William Gilmore Simms*, introd., vol. i (1952); Vernon L. Parrington, *Main Currents in American Thought*, vol. ii (1927). (M. C. S. O.)

SIMNEL, LAMBERT (*c.* 1475–1535), impostor and claimant to the English crown, the son of an Oxford joiner, was a cat's-paw in the conspiracies hatched to restore the Yorkist line after the victory of Henry VII (1485). A young Oxford priest, Richard Symonds, seeing in the handsome boy some alleged resemblance to Edward IV, determined to exploit him. In 1486, the rumour that the "princes in the Tower," Edward's children, were still alive, suggested that Simnel might be passed off as one of them; the year after, the false report of the death in the Tower of another young Yorkist, Edward, earl of Warwick, changed the impersonation. Symonds took his charge to Ireland where the Yorkist interest was strong, especially with the powerful house of Fitzgerald, earls of Kildare. In May 1487 Simnel was accepted as earl of Warwick and crowned at Dublin as King Edward VI, and despite Henry VII's efforts (which included parading the real earl through the streets of London) the conspiracy spread. In June 1487, Simnel landed in Lancashire, supported by 2,000 German mercenaries provided by Edward IV's sister Margaret, duchess of Burgundy, and in company with a genuine Yorkist claimant, John de la Pole, earl of Lincoln, who had abandoned his temporary loyalty to the Tudors. Although Lancashire gave them no support, the threat was, nevertheless, very real: Henry VII had to face it with what strength he could muster in the presence of a nation used to such disorders and ready to wait upon the outcome. This was settled in the Battle of Stoke (June 1487); Lincoln was killed, Simnel and Symonds were taken, the other Yorkist leaders disappeared. Symonds was kept in prison, but Henry VII displayed only sardonic contempt for Simnel whom he recognized to have been a harmless dupe. Employed in the royal kitchens, the pretender made a modest career for himself, dying soon after 1534.

See J. Gairdner, *Henry VII* (1889); J. D. Mackie, *The Earlier Tudors, 1485–1558* (1952). (G. R. E.)

SIMOCATTES, THEOPHYLACT (or THEOPHYLACTUS; Gr. THEOPHYLAKTOS SIMOKATTES) (fl. 6th–7th century A.D.), Byzantine writer whose history is a valuable source for the reign of Maurice (582–602). He was an Egyptian, who after legal training held office at Constantinople under Heraclius (610–641). His history, for which he had access to official sources of information, shows keen awareness of the Greek tradition of historiography, for he was acquainted with the work of Herodotus and Diodorus as well as later historians including near contemporaries. He also wrote a work on natural history (*Quaestiones naturales*) and a number of literary exercises in epistolary form.

His *Historia* was edited by C. de Boor in the "Teubner Series" (1887) and A. I. Bekker in the Bonn corpus (1834). Other works edited include *Quaestiones naturales*, ed. by J. L. Ideler, *Physici et medici graeci minores*, vol. i, pp. 168–183 (1841), and, together with the *Epistulae*, by J. F. Boissonade (1835); *Epistulae* ed. by R. Hercher, *Epistolographi Graeci*, pp. 763–787 (1873).

See K. Krumbacher, *Geschichte der byzantinischen Litteratur*, pp. 247–251, 2nd ed. (1897); G. Moravcsik, *Byzantinoturcica*, vol. 1, pp. 544–548, 2nd ed. (1958). (J. M. HY.)

SIMON, SAINT, one of the 12 apostles, always mentioned in the last of the three groups of four names in the apostle lists (Mark 3:18; Matt. 10:4; Luke 6:15; Acts 1:13). In Mark and Matthew he bears the surname *Kananaios*, or the Cananaean, often wrongly interpreted as meaning "from Cana" or "from Canaan." It is in fact the Greek transliteration of an Aramaic word *qan'anaya*, meaning "the Zealot," which is precisely the title given him by Luke both in his Gospel and in Acts. Whether he was one of the group of Zealots (the Jewish nationalistic party prior to A.D. 70) cannot be answered for lack of evidence. Nothing further is known about him from the New Testament. He is said to have preached the Gospel in Egypt and then joined St. Judas (Thaddaeus) in Persia, where both were martyred (according to the apocryphal Passion of Simon and Jude). Oct. 28 is the feast of SS. Simon and Jude. *See* also APOSTLE. (J. A. FI.)

SIMON OF ST. QUENTIN (fl. 1247), Dominican mission-traveler and diplomatist who accompanied the Dominican embassy, under Friar Ascelin or Anselm, which Pope Innocent IV sent in 1247 to the Mongols of Armenia and Persia. Large sections of Simon's history of this embassy have been preserved in Vincent of Beauvais's *Speculum historiale*. The embassy proceeded to the camp of Baiju, or Bachu *Noyan* (*i.e.*, "General" Baiju, *Noyan* signifying a commander of 10,000), at Sitiens in Armenia, 59 days' journey from Acre. The papal letters were translated into Persian, and thence into Mongol, and so presented to Baiju. But the Tatars were irritated by the haughtiness of the Dominicans and on July 25, 1247, the latter were dismissed with the *Noyan's* reply, dated July 20, which complained of the high words of the Latin envoys and commanded the pope to come in person and submit to the Master of all the Earth (the Mongol emperor). The mission thus ended in complete failure.

SIMON, SIR JOHN (1816–1904), English sanitary reformer, was born in London on Oct. 10, 1816. He studied medicine at St. Thomas's Hospital, and from 1840 held minor surgical posts at King's College Hospital. In 1847 he became surgeon and lecturer in pathology at St. Thomas's, retaining these posts until 1876. His pathological research led to his election to the Royal Society at the early age of 29, and his inventive and resourceful surgery soon secured him an outstanding position in that art. These scientific pursuits provided the groundwork for his chief occupation as a sanitary administrator. From 1848 to 1855 he held the position of first medical officer of health to the City of London. The much-publicized success of his pioneering efforts there made him a national figure and established the character of the medical officership in English local government thereafter.

Between 1855 and 1876 Simon was the first medical officer to the central government and his most fruitful years, 1858–71, were spent in this post. He gradually created a medical department of state to superintend the national health, established state scientific research, investigated all health concerns and published magisterial reports thereon, perfected the vaccination system, supervised the medical profession, and procured much legislation, including the Sanitary Act of 1866 which for the first time rendered a public health law universal, scientific, and compulsory. On being transferred in 1871 to the local government board, Simon found that the dominant lay secretariat frustrated his aims, and he resigned in 1876. His later life was spent in literary and professional work. He was created knight commander of the Bath in 1887. He died in London on July 23, 1904.

See R. Lambert, *Sir John Simon 1816–1904* (1963). (R. J. LA.)

SIMON, JOHN ALLSEBROOK SIMON, 1ST VISCOUNT (1873–1954), British lawyer and Liberal politician, who held four of the great offices of state: home secretary (1915–16 and 1935–37), foreign secretary (1931–35), chancellor of the exchequer (1937–40), and lord chancellor (1940–45). He was born in Manchester on Feb. 28, 1873, the son of a Congregational minister. Educated at Fettes College, Edinburgh, and at Wadham College, Oxford, he was elected a fellow of All Souls College, Oxford, in 1897, and was given the honorary degree of doctor of civil law by Oxford University in 1926. So devoted was he to Oxford that, at his express wish, his body was cremated in his D.C.L. gown.

Simon possessed exceptional intellectual gifts and a capacity for public affairs that raised him, through a successful career at the bar, to the front rank in politics. Yet, as a public figure, he earned a name for coldness and lack of humanity that both puzzled and wounded him. The explanation was the grief he suffered through the death in 1902 of his first wife Ethel Venables, less than four years after their marriage. In his autobiography, *Retrospect*

(1952), he wrote "The preachers are wrong who speak as though grief and disappointment are calculated to refine character. Far more men and women are soured by misfortune than are injured by prosperity." He married again in 1917 but those 15 years of loneliness made a permanent mark on his character.

Simon was called to the bar in 1899 and was elected Liberal M.P. for Walthamstow, in Essex, in 1906. He was made solicitor general in H. H. Asquith's government in October 1910, when he was knighted. Promoted attorney general in October 1913, he became home secretary in May 1915. There seemed nothing to stop his steady political advance, but in January 1916 he took a decision which excluded him from office until 1931: he resigned the post of home secretary as a protest against the government's decision to introduce conscription during World War I. This was an honorable act but, as Simon admitted years afterward, it was an error of judgment. He lost his seat in 1918 but returned to the House of Commons in 1922 as Liberal member for Spen Valley, in Yorkshire, which he represented until 1940 when he was created a viscount.

Simon was far from idle while out of office. His legal practice earned him more than £50,000 a year. He was chairman of the Indian Statutory Commission which, between 1927 and 1930, examined the constitutional future of India. During the world economic crisis of 1931, Simon abandoned his belief in free trade and advocated protection. Some other Liberals followed him and from 1931 to 1940 he was leader of a separate Liberal National Party that worked closely with the Conservatives. After the election of the National government (October 1931) Simon returned to office in November as foreign secretary. He was unable, acting through the League of Nations and in consultation with the United States, to stop Japan's occupation of Manchuria (1931). Simon became home secretary once more in 1935, and chancellor of the exchequer in 1937. He was created Viscount Simon in May 1940 and was lord chancellor from 1940 to 1945. He died in London on Jan. 11, 1954. (J. F. B.)

SIMON, JULES FRANÇOIS (1814–1896), French philosopher and political leader, the theorist of Radicalism who as prime minister in 1876–77 became a central figure in the formative crisis of the Third Republic, was born on Dec. 27, 1814, at Lorient (Morbihan). His father sent him first to school at Vannes and then (1833) to the École Normale in Paris. He taught philosophy at Caen and Versailles, and became a pupil at the Sorbonne, where he later lectured. He was elected to the National Assembly of 1848 as a liberal, devoted philosophically to the cause of freedom of speech, worship, and thought. He opposed the *coup d'état* of Louis Napoleon in December 1851 and was suspended from his academic post. Until 1863 he devoted himself to historical and philosophical work, producing several books of a semipopular kind. Then he took the necessary oath of allegiance to the empire and was able to secure election to the *Corps Législatif* in 1863. The coalition to which he belonged, the Union Libérale, polled some 2,000,000 votes, most of which came from the large towns. Simon was now firmly set on the path to a political career.

At first it was, for so staunch a liberal, a career of opposition and criticism. In religion a deist and (after 1870) a freemason, Simon brought to the support of the liberal opposition to Napoleon III a store of energy, subtlety, and ability which he concealed behind a serene and detached manner. In 1868 he published *La Politique radicale*, which later became, along with Léon Gambetta's Belleville manifesto of 1869, the basis of the Radical Party program. Reelected in 1869, he became a member of the Government of National Defense set up in Paris after the defeat of Napoleon III's army by the Germans at Sedan had destroyed the Second Empire. Sent to Bordeaux to get Gambetta to agree to peace, Simon was defied by that enthusiast for "a people's war" against the Germans; but on Feb. 18, 1871, Adolphe Thiers made him minister of education, religion, and fine arts in his emergency government.

Conditions were not favourable for Simon's favourite schemes of educational reform. He was bitterly opposed by the clerical parties, and contrived only to make certain reforms in secondary schools, though he deserves credit for achieving the basic task of getting schools in working order again after the upheavals of the war, the invasion, and the Commune of Paris. The author or editor of numerous works on philosophical subjects, and a member of the Académie des Sciences Morales et Politiques from 1863, he was elected to the Académie Française in 1875.

Simon fell from office with Thiers on May 18, 1873. His second tenure of power occurred in very different circumstances. The elections of 1876 returned a strong Republican majority to the Chamber of Deputies. President MacMahon, who succeeded Thiers, was committed, by temperament and affiliations, to a conservative and clerical policy. But the Republican gains obliged him, on Dec. 12, 1876, to invite Simon to form a ministry. Although relatively moderate, the ministry soon became involved in violent conflict with the clerical movements, and on May 16, 1877, MacMahon wrote Simon a letter which was tantamount to dismissal. Simon, although opposed to the more rabidly anticlerical measures of Gambetta or Jules Grévy, was undefeated in the chamber and could have defied the president. He weakly resigned, thereby precipitating the constitutional crisis of *le Seize Mai* (May 16), centring on the question whether ministerial responsibility was owed to the president or to the Chamber. Because events determined that it should be owed to the Chamber, MacMahon himself resigned on Jan. 30, 1879, and the Third Republic became essentially a parliamentary system.

Simon had played a mainly negative part in the crisis. He never regained office and rapidly lost political influence. He continued to engage in political journalism, but became a senator for life. He died in Paris on June 8, 1896, a half-forgotten figure of the formative years of the republic. He had published *Le Gouvernement de M. Thiers* in 1878. *Le Soir de ma journée* appeared posthumously (1902).

See L. Séché, *Jules Simon* (1898). (D. Tn.)

SIMON, RICHARD (1638–1712), French biblical critic, whose clear vision and accurate formulation of biblical problems and especially his insistence on the historicocritical method, pioneered modern biblical study, was born at Dieppe, May 13, 1638, and received his formal education under the Oratorians and the Jesuits, and at the Sorbonne. He joined the Oratorians in 1662, was ordained priest in 1670, was expelled from the Oratorians in 1678, and served as curé in Bolleville until 1682. Thereafter he continued his research and writing privately in Rouen, Paris, and Dieppe, where he died April 11, 1712.

Simon was too advanced for his age, and his method and its results were assailed by Roman Catholics (ten of his writings were placed on the *Index*) and Protestants alike. On his part, Simon opposed Spinoza's attempt to imbue the study of Scripture with rationalism, attacked the Protestant abandonment of tradition, and struck at Roman Catholic neglect of historical (scriptural and traditional) theology.

Paradoxically, the Lutheran biblical critic J. S. Semler coloured Simon's method and views with rationalism, and in this guise they became the staple of rationalistic higher criticism, thus rendering Simon's work further suspect for Roman Catholics. Since 1900, however, he has generally been accorded due recognition as a Catholic scholar.

Simon's best-known work is the *Histoire critique du Vieux Testament.* The first edition (1678) was confiscated; a faulty edition made from the few surviving copies appeared in Amsterdam in 1680, but the best edition, supervised by the author himself, was published at Rotterdam in 1685. Other works include: *Du Texte du Nouveau Testament* (1689); *Des Versions du Nouveau Testament* (1690); *Des Principaux commentateurs du Nouveau Testament* (1693); and *Nouvelles observations sur le texte et les versions du Nouveau Testament* (1695).

Bibliography.—A complete critical study of Simon and his work is still wanting, but the following may be profitably consulted: A. Bernus, *Richard Simon et son Histoire Critique du Vieux Testament* (1869); H. Margival, *Richard Simon et la critique biblique au XVII^e siècle* (1900); F. Stummer, *Die Bedeutung Richard Simons für die Pentateuchkritik* (1912); A. Molien, in *Dictionnaire de théologie catholique*, vol. xiv, col. 2094–2118 (1941); R. Deville, "Richard Simon, critique catholique du pentateuque," in *Nouvelle revue théologique*, 73:723–739 (1951); J. Steinmann, *Richard Simon et les origines de l'exégèse biblique* (1960). (J. P. W.)

SIMONIDES of Ceos (*c.* 556–*c.* 470 B.C.), ancient Greek lyric poet and epigrammatist who appears to have originated the literary form of the epinician ode (*i.e.*, ode in honour of victors in the great games at Olympia) and to have been the first Greek author to write on commission, for fees. A native of Iulis on the Aegean island of Ceos (now Kea [Keos]), he studied music and poetical composition at home, but left the island as a young man and seems to have lived mostly in Athens thereafter. Quotations and allusions in later writers connect him with the "tyrants" of Athens, of Crannon and Larissa in Thessaly, and of Syracuse, where he is said to have died; but he did not depend entirely on patronage—his epinician for an Olympic victor of 520 B.C. is the earliest such poem recorded, and later writers refer to his professionalism.

Though he was often successful in the Athenian competitions for dithyrambic poetry (*q.v.*), he seems to have preferred men to gods as subjects for poetry: the surviving remains of his choral lyrics include fragments of songs in honour of those who fought at Thermopylae and Salamis, and his poem of advice to Scopas of Crannon is extensively quoted in Plato's *Protagoras;* the extant epigrams —for which he was so famous that many which he cannot have written are ascribed to him—were mostly intended as epitaphs or for dedicatory inscriptions. The fragments illustrate his reported comparison of poetry to verbal painting and of painting to mute poetry. Ionian by birth and adaptable and progressive by temperament, he was better fitted than Pindar, the conservative Theban, to express the panhellenic ideals of the new age which developed after the Greek victories over the Persians. Bacchylides (*q.v.*) was his nephew.

Bibliography.—Lyric poems in D. L. Page, *Poetae melici Graeci*, pp. 237–325 (1962); epigrams in E. Diehl, *Anthologia lyrica Graeca*, vol. ii, pp. 84–118 (1925); allusions and anecdotes in J. M. Edmonds, *Lyra Graeca*, vol. ii (1924). *See* also C. M. Bowra, *Greek Lyric Poetry*, 2nd ed. (1961), *Pindar* (1964). (Jn. A. D.)

SIMON MAGUS (1st century A.D.), according to Acts 8:5–24, a magician regarded by many inhabitants of Samaria as "that power of God which is called Great"; after being converted and baptized by the evangelist Philip, he offered money to two of the apostles for the power to impart the Spirit (hence the word "simony"). Rebuked by Peter, Simon requested the apostles' prayers. The conclusion of this story in Acts is probably intended to imply that Simon's repentance was genuine; but later Christian writers, such as Justin, Irenaeus, Hippolytus, and Epiphanius, treat him as the originator of Gnosticism (*q.v.*). Practically nothing is known of the process which produced Simonianism, though presumably before and after his Christian period Simon was regarded as an incarnation of some god's power because of his ability to perform miracles. Apparently he was a Christian long enough to learn something about Jesus and to develop doctrines about himself in relation to christological thought. According to the *Clementine Homilies* (*see* Clementine Literature) he was originally a disciple of John the Baptist; he may conceivably have had some relation to the covenanters of Qumran (for which *see* Dead Sea Scrolls).

At a later time Simon seems to have journeyed to Rome in the company of a Tyrian ex-prostitute named Helen, who he claimed was his First Thought, through whom he himself created the universe. She had been imprisoned by angels and powers who had emanated from her, and had passed through a succession of incarnations, once as Helen of Troy. Simon, the Father, had descended to rescue this "lost sheep" (cf. Luke 15:6). Parts of this myth recall the Oriental myths about the imprisonment of Inanna, Sumerian queen of heaven, and other goddesses. In Rome Simon probably made some converts, since in the second century at Rome it was claimed that a statue bearing an inscription to the god Semo Sancus had been erected *Simoni deo sancto* (Justin, *Apol.*, i, *26, 2*).

Probably in the 2nd century, Simonians stated that Simon had appeared among the Jews as Son and had seemed to suffer, had descended in Samaria as Father, and had come among the rest of the nations as Holy Spirit. This quasi-Trinitarian picture is clearly Christian in origin, as is the Simonian statement that those who have placed their hope on Simon and Helen are "saved by his grace, not by just works" (cf. Eph. 2:8–9).

The Simonians regarded Zeus and Athena as equivalent to Simon and Helen, and the myth of the birth of Athena is not unlike that of Helen's origin. The Simonians made use of all kinds of materials and developed their theology (or rather theologies; the "Great Pronouncement" which Hippolytus ascribes to Simon has connections with Stoicism and with other Gnostic systems) in highly imaginative fashion. How much of their thought goes back to their founder is impossible to determine, but it cannot be demonstrated that the essentials of the system are pre-Christian.

See R. P. Casey, "Simon Magus," in F. J. F. Jackson and K. Lake, *The Beginnings of Christianity*, vol. 5 (1933); R. M. Grant, *Gnosticism and Early Christianity* (1959). (R. McQ. G.)

SIMONSTOWN (Simonstad), a town and naval base of Cape of Good Hope Province, S.Af., lies 22½ mi. (36 km.) S. of Cape Town by road. Pop. (1960 census) 8,635, comprising 3,518 Europeans, 3,584 Coloureds, 1,414 Bantu, and 119 Asians. Among places of interest are the Admiralty House (1814), the church of St. Francis of Assisi (1814, rebuilt 1834—the first English church founded in South Africa), the still older naval cemetery, and the Residency (1776), with its former slave quarters. There are facilities for bathing, golf, and tennis. An industrial site has been established and there is a fish-oil refinery, fishing being one of the main occupations. The town is linked by bus and electric train with Cape Town.

Named after Simon van der Stel, governor of the Cape during 1679–99, Simonstown was a Dutch military and naval depot from 1741. In 1814 it became the headquarters of the British South Atlantic Naval Squadron. In 1957 it was transferred to South Africa, Britain being guaranteed continued use of its facilities.

SIMONY is defined as the buying or selling for a temporal (*i.e.*, material) price something spiritual or closely connected with the spiritual. More widely, it is any contract of this kind forbidden by divine or ecclesiastical law. The name is taken from Simon (Acts 8:18), who endeavoured to buy from the apostles the power of conferring the gifts of the Holy Ghost (*see* Simon Magus). Simony in the form of buying holy orders or church office was virtually unknown in the first three centuries of Christian life but became familiar when the church had positions of wealth and influence to bestow. The first legislation on the point was the second canon of the Council of Chalcedon (451); thenceforward prohibitions and penalties were reiterated against buying or selling promotion to the episcopate, priesthood, and diaconate. Later the area of the offense was held to cover all traffic in benefices, and later still it was widened by ecclesiastical law to cover pecuniary transactions on Masses (apart from the authorized offering), blessed oils, and other consecrated objects, and finally included any lucrative action, such as resignation or withdrawal in favour of another, connected with an ecclesiastical benefice. In the case of holy orders the penalty was always suspension of both the bestower and the recipient and deprivation of any benefice concerned.

From an occasional scandal, simony became endemic in Western Europe in the 9th and 10th centuries, when regalian and other proprietary rights over prelacies and churches prevailed throughout Europe in feudal society, and the "heresy" of simony became a major object of attack on the part of the papacy in the age of Gregory VII. The traditional canonical sanctions were rigorously applied, and simony at the high levels of church life became once more occasional rather than normal, though throughout the Middle Ages numerous cases occurred in the episcopate and even in the papacy. More common still were the purchase of benefices and the organized traffic in offices both at the Curia and in the various regional churches.

Simony in its most flagrant forms gradually disappeared from the 16th century onward with the disendowment and secularization of church property, but in the Church of England, where the medieval system has continued in a modified form to the present day, simony has remained a real, if rare, source of offense. In the modern Roman Catholic Church relevant legislation has chiefly dealt with abuses connected with Mass stipends.

SIMOOM: *see* WIND.

SIMPLICIUS, SAINT (d. 483), pope from 468 to 483, was born at Tivoli. During his pontificate the Western Empire was overthrown, and Italy passed into the hands of the barbarian king Odoacer (476). In the East, the usurpation of the empire by Basiliscus (475–476), who supported the Monophysites, gave rise to many ecclesiastical troubles. The emperor Zeno, having procured the removal of Basiliscus, endeavoured to compound with the Monophysite party; and Acacius, bishop of Constantinople, who had previously been on the pope's side in defense of the Council of Chalcedon, abandoned Simplicius and subscribed to the *Henoticon*, the conciliatory document promulgated in 482 by the emperor. Simplicius died on March 2, or perhaps March 10, 483. He is commemorated on March 2. *See* also PAPACY.

SIMPLICIUS (6th century A.D.), Greek philosopher, a native of Cilicia, was a pupil of Damascius at Athens and of Ammonius at Alexandria; his work displays the influence of both these schools of Neoplatonism (*q.v.*). The school of philosophy at Athens having been disendowed and its teaching forbidden (529), Damascius, Simplicius, Priscianus, and four others resolved in 531 or 532 to seek refuge with Chosroes, king of Persia, but within two years they returned to Greece.

After his return Simplicius wrote commentaries on Aristotle's *De coelo*, *Physica*, *De anima*, and *Categoriae*, which, with a commentary on the *Enchiridion* of Epictetus, have survived. These contain many valuable fragments of the older philosophers as well as of his immediate predecessors. One of his general principles is that Aristotle is in harmony with Plato, being opposed only to a superficial understanding of his words. (D. J. A.)

SIMPLON PASS, Switzerland, lies in the Lepontine Alps at 6,578 ft. (2,005 m.) on the watershed between a north-flowing tributary of the Rhône and a south-flowing tributary of the Toce. It was not till the mid-13th century that it attained any importance as a routeway and it was only with the building (1800–07) of a carriage road (which negotiates the Gondo Gorge) by Napoleon that it began to compete with the other Alpine passes as a major link between central and southern Europe. Near the summit of the pass is the hospice, first mentioned in 1235 as in the charge of the Order of St. John; it is now occupied by the Augustinians, having been given over to that order by Napoleon in gratitude for their hospitality on his passage (1800) over the Great Saint-Bernard Pass. Bellevue Simplon-Kulm Hotel stands near the hospice. A railway tunnel opened in 1906 passes 4,430 ft. (1,350 m.) beneath the pass. It is about 12 mi. (20 km.) long and connects Brig, Switz., with Iselle, Italy. When the pass is closed to road traffic, usually from mid-October to early April, cars are transported through the tunnel by train. (A. F. A. M.)

SIMPSON, SIR JAMES YOUNG (1811–1870), Scottish obstetrician, whose fame rests principally upon his pioneer work in the introduction of anesthesia into midwifery practice, was born at Bathgate, Linlithgowshire, Scot., on June 7, 1811. He was sent at the age of 14 to Edinburgh University and obtained his M.D. degree in 1832. He was elected senior president of the Royal Medical Society of Edinburgh in 1835 and in 1837–38 acted as deputy for John Thomson, professor of pathology. In 1840 he was appointed to the chair of midwifery in the university. When news of the first trials of ether reached Scotland in 1846, Simpson immediately realized its potential value and tried it in obstetric practice. In March 1847 he advocated its use in a paper read before the Royal Medical Society. He continued, however, to make systematic search for more efficient anesthetics, carrying out many self-experiments with his assistants, and on Nov. 4, 1847, he discovered the anesthetic properties of chloroform. He published a full account of chloroform (1847) in which he stressed its advantages over ether and strongly advocated its use in surgical operations and in obstetric practice.

The use of chloroform for the relief of pain in childbirth was violently opposed both on medical and on theological grounds, but Simpson's uncompromising advocacy and, finally, the administration of chloroform to Queen Victoria at the birth of Prince Leopold in 1853 silenced all opposition.

Apart from his great work on anesthesia, Simpson made contributions of permanent value to many departments of obstetrics and gynecology. His principal writings are *Obstetric Memoirs and Contributions* (2 vol., 1855–56); *Selected Obstetrical and Gynaecological Works* (1871); *Anaesthesia, Hospitalism, Homoeopathy, etc.* (1871); *Clinical Lectures on the Diseases of Women* (1872). He was also greatly interested in archaeology and in the history of medicine; two volumes of his *Archaeological Essays* were published in 1873. He was appointed one of the queen's physicians for Scotland in 1847 and in 1866 was created a baronet. He died on May 6, 1870, in London.

SIMROCK, KARL JOSEPH (1802–1876), German literary scholar and poet, was born at Bonn on Aug. 28, 1802. Simrock's great achievement was to make available for his generation a vast body of earlier Germanic literature, either by translation into modern German (*Das Nibelungenlied*, 1827), by rewriting (*Das Amelungenlied*, 1843–49), or by editing (*Die deutsche Volksbücher*, 18 volumes, 1839–67). He also translated many of Shakespeare's plays and in 1855 published a *Handbuch der deutschen Mythologie*.

As a young man Simrock studied law at Bonn and Berlin but also attended literary lectures by A. W. Schlegel and Karl Lachmann (*qq.v.*). In 1830 he was dismissed from his judicial appointment for writing a poem in praise of the July Revolution, but the death of his father shortly after left him in comfortable circumstances and he retired to Bonn to devote himself to literary studies. He died there on July 18, 1876, having been made an honorary professor in 1850.

See *Ausgewählte Werke*, ed. by G. Klee, with biography, 12 vol. (1907); N. Hocker, *K. Simrock* (1877). (G. T. HU.)

SIMS, WILLIAM SOWDEN (1858–1936), U.S. naval officer who by his persistent efforts to improve ship design, fleet tactics, and naval gunnery influenced the Navy, so it was said, "more than any other man who ever wore the uniform." He was born on Oct. 15, 1858, at Port Hope, Ont., where his father, a U.S. engineer, was then employed. The family moved to Pennsylvania in 1872 and William, after being rejected once, entered the U.S. Naval Academy. After graduating in 1880 he served almost continuously on sea duty for the next 17 years. While attached to the nautical school ship "Saratoga" (1889–93) he prepared a text on navigation that was used for many years in both the naval service and the merchant marine.

At the end of the century (1897–1900) Sims served as naval attaché to the U.S. embassies in Paris and St. Petersburg. His observation of foreign navies convinced him of the comparative inferiority of the U.S. Navy. From the China Station, where he served from 1900 to 1902, he sent to the Navy Department a series of remarkable reports setting forth the defects in U.S. ships and naval marksmanship. In several papers he described a new system of gunnery that had been developed by Capt. Percy Scott, the great British officer who was also serving on the China Station. Receiving no satisfactory response from the Navy Department, Sims wrote directly to Pres. Theodore Roosevelt, who brought him to Washington as inspector of target practice. After seven years in this position Sims returned to sea duty with the reputation of "the man who taught the Navy how to shoot."

In the next eight years (1909–17) he was captain of two different battleships and commander (1913–15) of the Atlantic Torpedo Flotilla where he developed an imaginative tactical doctrine for destroyers, then a new type of naval vessel. After the United States entered World War I he became commander of the U.S. Naval Forces Operating in European Waters, with headquarters in London. His most notable contributions to the victory at sea were his part in promoting adoption of the convoy system and his great success in working cooperatively with the naval commands of the Allied powers.

Returning to the United States in 1919 Sims was reassigned,

at his own request, to duty as president of the Naval War College in Newport, R.I. Resenting awards of decorations to many officers whom he considered undeserving, he refused to accept his own Distinguished Service Medal. From Newport he wrote a letter to the secretary of the navy severely criticizing the manner in which the Navy Department had administered the naval effort in the war. There followed an extended congressional investigation which produced inconclusive and partisan judgments. Shortly thereafter Sims, who had earlier reached the temporary rank of admiral, retired from the Navy on Oct. 15, 1922. He died in Boston, Mass., on Sept. 28, 1936.

See Elting E. Morison, *Admiral Sims and the Modern American Navy* (1942). (E. E. Mo.)

SIN, name of the moon god of the Babylonian-Assyrian pantheon, derived from old-Akkadian *zu-en* (usually written *en-zu*), "lord of wisdom." His Sumerian name is Nanna. Son of Enlil, he was head of the secondary cosmic triad of the Akkadian pantheon, its two lesser members being his son and daughter, Shamash and Ishtar (*qq.v.*). (In Sumer this triad was absorbed into the corresponding Sumerian triad of Nanna, Utu, and Inanna.)

The chief seats of Sin's worship were Ur in southern Babylonia and Harran in northern Assyria, where he was styled "lord of Harran," but temples are found in all the large cities of Sumer, Babylonia, and Assyria in his honour. His chief function was to be the "lamp of heaven and earth." He and his son Shamash open the gate of Anu, the chief god of heaven. He is "lord of the months."

Sin is represented with flowing beard and with the crescent above his horned tiara, on seal cylinders and on the great stela of King Ur-Nammu (*c.* 2130 B.C.). Later, his symbol is often the crescent alone. In the astral-theological system he is represented by the number 30 (obviously connected with the 30 days' average duration of the moon's course); while the planet Venus (*i.e.*, his daughter Ishtar) is represented by the number 15. As "lord of signs" and of "decisions" (*e.g.*, at the waning of the moon) he is named in omen literature.

In Assyria the cult of the moon god seems to have been less prominent than in Babylonia. He occurs frequently in inscriptions alongside Shamash and Ashur, the head of the Assyrian pantheon; but his shrines do not seem to have great local or national importance, except at Harran. Nabonidus, the last king of Babylon (556–539), whose mother was a priestess of Sin at Harran, inaugurated a movement to elevate the cult of Sin to the supreme place in the pantheon.

At an earlier time the emphasis placed upon moon worship by Sargon of Akkad (*c.* 2350–2300 B.C.) may have been due to his western Semitic origins. In Arabia and among all the Semitic peoples of western Asia the moon god was a most important deity.

The consort of Sin was Ningal to whom a special temple was built at Ur, and her cult was widely known in Syria. The cult of the Babylonian Sin seems to have been particularly favoured by the Assyrian colony in Cappadocia early in the 2nd millennium B.C., and there is evidence of his cult among the Hittites of Anatolia and Syria.

SIN is the name given to moral evil when considered from the religious point of view. In ancient Greek thought sin was looked upon as in essence a failure on the part of man to achieve his true self-expression and to preserve his due relation to the rest of the universe; it was attributed mainly to ignorance. Christianity, while not denying this aspect, sees sin as a deliberate violation of the will of God attributable to man's pride, self-centredness, and disobedience. In this respect the Christian view is in direct continuity with the Old Testament and with Judaism. While insisting more strongly than most religions upon the gravity of sin, both in its essence and in its consequences, Christianity has emphatically rejected the Manichaean doctrine that either the created world as a whole or the material part of it is inherently evil (*see* MANICHAEISM). It holds that evil is the result of the misuse of their free will by created beings, both angelic and human, and that the body, with its passions and impulses, is to be neither ignored nor despised but sanctified; in the Bible, the "flesh" which is spoken of disparagingly is not the human body but human nature in rebellion against God.

Theologians divide sin into "actual" and "original." Actual sin is sin in the ordinary sense of the word and consists of evil acts whether of thought, word, or deed. Original sin (the term can be misleading) is the morally vitiated condition in which we find ourselves at birth as members of a sinful race. In Gen. 3 this is depicted as an inherited consequence of the first human sin. Theologians differ as to the interpretation of this narrative, but it is agreed that original sin, however mysterious its origin and nature may be, arises from the fact that we come into the world not as isolated individuals but as members of a corporate human race inheriting both good and evil features from its past history.

Actual sin is subdivided, on the basis of its gravity, into mortal and venial. This distinction is often difficult to apply but can hardly be avoided. Mortal sin is a deliberate turning away from God, sin in a grave matter committed in full knowledge with full consent of the will; until it is repented it cuts the sinner off from God's sanctifying grace (*see* GRACE). Venial sin, while it weakens the sinner's union with God, is not a deliberate turning from him and so does not wholly block the inflow of sanctifying grace.

Actual sin is also subdivided into material and formal. Formal sin is both wrong in itself and is known by the sinner to be wrong; it therefore involves him in personal guilt. Material sin consists of an act which is wrong in itself (because contrary to God's law and man's moral nature) but is not known to be wrong and so is not culpable.

See also SINS, SEVEN DEADLY; and references under "Sin" in the Index.

See R. C. Mortimer, *Elements of Moral Theology*, ch. iii–v (1947); N. P. Williams, *Ideas of the Fall and of Original Sin* (1927). (E. L. M.)

SINAI, the name given to the triangular peninsula lying between Egypt, Israel, and Saudi Arabia, with the Mediterranean forming its northern boundary, the Suez Canal and Gulf of Suez on the west, and the Gulf of Aqaba to the southeast. Sinai is usually regarded geographically as part of Asia, but politically is a desert governorate of the United Arab Republic (Egypt). Area 23,200 sq.mi. (60,088 sq.km.). Pop. (1960) 126,000.

The oldest rocks and the highest mountains in Sinai are to be found in the southern third of the peninsula, an extension of the Red Sea Hills of the African mainland. These form a complex of Precambrian crystalline rocks: gneisses and schists into which were intruded masses of igneous plutonic rocks with varied igneous dikes veining the whole great complex. They form high, rugged mountains predominantly red in colour, from which the Red Sea takes its name. In the west, basaltic lava flows, probably of Miocene age, rest upon the old rocks. Along the Gulf of Suez coast a narrow plain of recent rocks separates the mountains from the sea except just south of the Wadi Fayran (Feiran) where for 20 mi (32 km.) abrupt cliffs of red granite rise from the shore. All along the shore of the Gulf of Aqaba the Sinai Mountains rise in a precipitous wall. North of the Wadi Fayran outcrops of red (Nubian sandstone terminate the ancient core of the peninsula. Against them to the north in a series of dissected scarps successively younger strata outcrop, mainly of limestone of Cretaceous and Eocene age. The gravel-covered central part of the limestone plateau, known as the wilderness of At Tih ("the wandering") averages 3,000 ft. (914 m.); its highest part, Jabal al 'Ajmah (Egma) in the south, attains 5,335 ft. (1,626 m.). To the north the land slopes down to the Mediterranean, its surface broken by inlier of older rocks creating marked limestone and sandstone hill masses, principally Yu'alliq (3,570 ft. [1,088 m.]), Hilal, both of Middle Cretaceous series, and Magharah of Jurassic age. Near the Mediterranean shoreline is a broad tract of sand dunes, some over 300 ft. (91 m.) high. This northern shoreline, fringed with salt marsh is sinking. In the west this is compensated for locally by the eastward drift of Nile sediment.

The granite peaks in the south, the highest mountains in the governorate of Sinai, include Mt. Catherine or Jabal Katrinah (8,651 ft. [2,637 m.]), Umm Shawmar (8,482 ft. [2,585 m.]), Ath Thabt (7,997 ft. [2,437 m.]), and Musa or Mt. Sinai (7,482 ft. [2,228 m.]). The area is difficult of access: deep, rocky gorges hem in the maze of sharp ridges and gaunt peaks. This mountainous area receives a few inches of rain each year, mostly in irregular, heavy downpours, insufficient for agriculture but sustaining springs and wells, and in a few bordering wadis small streams flow and nourish oases, such as at Feiran. The greater part of the scanty drainage of the northern two-thirds of the peninsula is ultimately to the Wadi al 'Arish which, rising in Al 'Ajmah Plateau, eventually reaches the Mediterranean. For most of the year the plateau is waterless except for a few permanent springs, as at An Nakhl. The Wadi al 'Arish rarely carries water to the sea, but water is obtained from wells dug in its bed and a small dam has been built. Underground water is also tapped by wells in the hollows between dunes along the northern coast where, four or five feet down, a foot or so of fresh water rests on salt.

The climate is healthful. In the mountain regions the nights are usually cold, but over most of the peninsula the heat of summer is intense. The rainy period of winter often results in serious floods. In a normal year there is sufficient rainfall to support scrub and tamarisk bushes and even a few poor crops. There are date palms at Al 'Arish, Feiran, and At Tur.

Animals are rare. They include ibex, gazelle, sand fox, leopard, wildcat, jackal, hare, hedgehog, and mole. Falcons and eagles are indigenous, and there are also the seasonal migrants such as quail, partridge, and grouse, which are shot for food as are the ibex and gazelle.

Sinai is sparsely populated by *bedu* (Bedouin *q.v.*) tribes, which are divided into two main groups. In the south the most numerous are the Sawalihah; in the north, the Terabin. The people of the coastal area are an admixture, and after 1948 there was a great influx of refugees encamped in the Gaza strip. A small group, the Jebeliyeh, living round St. Catherine's Monastery, are said to be the direct descendants of Bosnian and Wallachian serfs settled there by Justinian as guards for the monastery and forcibly converted to Islam at the time of the Arab invasion. The majority of the sedentary population lives near the north coast, especially at Al 'Arish, the administrative centre (pop. [1957 est.] 15,400) and at Al Qantarah ash Sharqiyah on the eastern side of the Suez Canal (pop. 13,384).

The railway between Palestine and Egypt was inoperative after 1948. The main paved road runs from Ismailia (Al Isma'iliyah) to Abu 'Uwayjilah, where it forks, one branch going north to Gaza and the other to Al 'Awja'. The old pilgrim route, still in use, runs from Suez via An Nakhl, Ath Thamad, and Aqaba to Medina and Mecca. Most of the country is not suitable for wheeled vehicles but it is possible to pass along the wadi beds when these are not in flood. Inaccessibility has delayed exploration and development of mineral resources. Manganese is worked at Umm Bugma, 65 mi. (105 km.) S of Suez; and after World War II oil fields were developed beside the Gulf of Suez, at Sudr, Wadi Fayran, and Al Bala'im. These fields account for four-fifths of Egypt's total production. (A. B. M.)

History.—The name Sinai is thought to be derived from the Akkadian moon-god Sin. Mt. Sinai is famous as the scene of the giving of the law to Moses and the entering of the Israelites into a covenant with the Lord, but there is considerable doubt as to which of the mountains of Sinai was the relevant site. Jabal Sirbal was originally so accepted, with the result that the city of Paran was built at its foot and in time became a cathedral city and a bishopric; but the claims of Mt. Sinai were later preferred, and on this mountain was built St. Catherine's Monastery.

In the Wadi al 'Arish, at 'Ayn al Qusaymah, Bi'r Hasanah, and An Nakhl, implements of Acheulo-Levalloisian type were discovered, and it is therefore thought that Paleolithic man was present in north, central, and southwestern Sinai. Neolithic and Chalcolithic remains were found on the Ismailia-Bi'r Hasanah track. Stone circles, rectangular stone ruins, and circular tombs, all of uncertain date, occur in the Wadi Sulaf and in many other regions of the peninsula. The ancient Egyptians mined turquoise and copper in the mountains, in the Wadi Magharah, and in the Feiran Oasis; their inscriptions date from the 1st dynasty. At Sarabit al Khadim, Sir W. M. Flinders Petrie found a temple dedicated to Hathor. It was used by the mine workers and contained records and inscriptions of many of the Middle and New Kingdom rulers. The last Egyptian king to make recorded offerings at this place was Ramses V of the 20th dynasty.

The Sarabit inscriptions collected by Petrie and published by A. H. Gardiner and E. T. Peet may be the earliest alphabetic script, but the matter is still undecided. The passage of the Israelites through Sinai and the route and date of the Exodus are still matters for argument. At Shaykh Zuwaid in the north of Sinai there is an Egyptian frontier fortress dating at least from the time of the 18th dynasty, and it is likely that there was a chain of these fortresses extending along the northern coastal route. There is evidence from the texts and from surface finds that the Egyptians held all this region at the time when they were effectively controlling Palestine and Syria. After the decline of the Egyptian Empire, Nabataeans from Petra controlled the trade routes of the Wadi 'Arabah and the peninsula during the first two centuries B.C., until they were defeated by the Romans in A.D. 106. The region then became the Arabian province of the Roman Empire, and a capital was established at Bozrah (modern Bosra).

During the early Christian period Sinai became the home of a large number of hermits, particularly in the southern mountain region.

The building of the monastery of St. Catherine dates from A.D. 530 when Justinian I, after complaints of robber incursions from the monks who had settled there, fortified the traditional site of the burning bush observed by Moses on the lower slopes of Mt. Sinai. This provided a centre for the scattered communities of Christians, and was spared by the invading Muslims; to conciliate the latter, the monks, according to tradition, erected the small mosque that stands within the walls. The monastery was a pilgrimage centre during the Middle Ages. It still retains much of its original appearance and has had an unbroken history since the 6th century. The original gray granite walls (280 x 250 ft. [85 x 76 m.]) still stand, and so does the church dedicated to the Virgin Mary, which was built at the same time. In the apse is a mosaic of the Transfiguration, probably also dating from this period, though it has been restored. The monastery's greatest treasures are its icons, some of which are prior to the 8th century, and its manuscripts. These, housed in the library built in 1945, are mainly in Greek and Arabic. In 1949–50 most of these manuscripts were microfilmed by the American Foundation for the Study of Man, acting on behalf of the Library of Congress and with the assistance of the University of Alexandria.

The most important manuscript now in the monastery is the Codex Syriacus, a Syriac text of the Gospels written about 400. The Codex Sinaiticus, now in the British Museum, is a Greek manuscript of the Bible dating to the 4th century.

After 1517 Sinai formed part of the Ottoman Empire and the country was administered by an official from Constantinople. When Egypt became independent of Turkey, conditions in Sinai deteriorated and traveling became difficult. Order was not restored until 1831, when Ibrahim Pasha, son of Mehmed Ali, advanced through Sinai and defeated the Turks at Acre. At the Treaty of London in 1840 Egypt was nominally restored to Turkish rule, and remained in this position until the outbreak of war in 1914. In October of that year Turkish forces seized Al 'Arish, and in 1915 and 1916 they advanced to the Suez Canal, but were driven off. In January 1917 the Battle of Rafah in northern Sinai marked the final advance of the British Army through the country. At the end of World War I Sinai was returned to Egypt and has since been administered by that country. After 1948 the Sinai-Israeli border was the scene of frequent frontier incidents. In 1956 the Israeli Army advanced through Sinai to the Suez Canal, defeating units of the Egyptian Army. They withdrew in 1957 at the behest of the UN General Assembly.

As the land bridge between Asia and Africa, Sinai retains considerable importance in Middle Eastern affairs. (M. V. S.-W.)

SINAI, ORTHODOX CHURCH OF MOUNT. The Greek Orthodox Church of Mt. Sinai (often incorrectly called the Sinai Independent Greek Orthodox Church) consists of the fraternity of the monastery of St. Catherine on Mt. Sinai, which is situated more than 5,000 ft. (1,500 m.) above sea level in a narrow valley north of Jabal Musa in the Sinai Peninsula of Egypt. It is the smallest of the autonomous churches that together compose the Orthodox Eastern Church (*q.v.*). The abbot of the monastery, who is also the archbishop of Sinai, Paran, and Raithu, is elected by the brotherhood and consecrated by the Greek Orthodox patriarch of Jerusalem. Founded by the Byzantine emperor Justinian I in 527, the monastery became an important centre of Orthodox spirituality. One of its early abbots was St. John (*q.v.*) Climacus. The monastery was at first under the jurisdiction of the Jerusalem patriarch; its independence was recognized by Constantinople in 1575. There are about 20 monks belonging to the monastery (whose numbers are limited to 36); this figure includes those living in its annexes (*metochia*) elsewhere, chiefly at Cairo and Suez. The laity of the Church of Sinai are some Christian Arabs employed by the monastery and fishermen on the Red Sea coast at At Tur (Tor; formerly Raithu). The Bedouin Arabs who live near the monastery have always acted as its guards and have in their turn been supported by it; although Muslims, they are devoted to the monastery, within whose walls is a small mosque where they worship. The monastery's greatest treasures are its manuscripts (which once included the Codex Sinaiticus now in the British Museum) and its icons, some from the pre-iconoclastic period of Byzantine art (*see* further SINAI).

SINAIA, a health resort town and scenic spot in the *regiune* (administrative and economic region) of Ploeşti, Rumania, lies on the Prahova River, 2,770 ft. (844 m.) above sea level, in the southeastern foothills of the Bucegi Mountains in the Transylvanian Alps, and 78 mi. (126 km.) NNW of Bucharest. Pop. (1960 est.) 9,717. It has modern hotels and rest houses, mountain refuges, and winter-sports facilities. The Peleş Museum contains collections of paintings, furniture, and carpets. There are food-processing and metallurgical industries, and the town is connected by rail and road with Ploeşti and Braşov.

SINALOA, a Mexican state on the Gulf of California and Pacific Ocean, established in 1830. Pop. (1960) 838,404; area 22,429 sq.mi. (58,092 sq.km.). Sinaloa is bounded north by Sonora, east by Chihuahua and Durango, and south by Nayarit, with about 400 mi. of coast on the west. The state is coastal, barren and tropical, with mountains on its eastern border. Five main streams and river valleys run from these mountains to the coast. Each river valley system is relatively isolated and is the scene of extensive irrigation, hydroelectric, and communications projects. The Miguel Hidalgo Dam on the Fuerte River, completed in 1956, waters about 123,550 ac.

Sinaloa is primarily an agricultural area which raises wheat, chick-peas, cotton, tobacco, sugarcane, tomatoes, fruits, and winter vegetables on irrigated lands. Local manufactures include beer, ice, cigarettes, cooking oils, soap and cotton textiles; there is an iron foundry and a plating and galvanizing establishment. The most important coastal industry is fishing, chiefly for sharks, the livers of which yield vitamin products, and for shrimps, processed locally. Tourism and game fishing are also significant.

The backbone of Sinaloa is the Mexican Southern Pacific Railway, acquired from its U.S. owners by Mexico in 1951. It runs from Nogales to Guadalajara and, in its course through Sinaloa, parallels the coast and ties the river valleys together. A spur of the Southern Pacific line extends to the water's edge at Mazatlán, where there are improved port works and a large airport. The Pacific highway, which reaches Nogales, ties Culiacán (*q.v.*), the state capital and commercial centre, to Mazatlán (*q.v.*), and both to Guadalajara. A railway between Mazatlán and Durango opened agricultural and mining outlets. The latter are of considerable importance, as Sinaloa produces salt, graphite, manganese, gold, silver, copper, iron and lead. (J. A. CW.)

SINANTHROPUS (PEKING MAN). Remains of this significant fossil were found in a cave or fissure filling at Chou-k'ou-tien, near Peking (*see* CHINA: *History*). The site was discovered in 1921 by J. G. Andersson, W. Granger, and O. Zdansky; the latter conducted the first excavations in 1923. In a Middle Pleistocene faunal assemblage, including rhinoceros, deer, horse, pig, bear, sabre-toothed tiger, hyena, and giant beaver, several human teeth were found (*Homo* sp.): a large lower molar of unusual pattern was discovered by B. Bohlin in October 1927. This single tooth led Davidson Black (*q.v.*) to infer a previously unknown hominid genus and species, which he named *Sinanthropus pekinensis*.

By the 1960s remains of about 45 individuals of *Sinanthropus* had been found, including many isolated teeth, parts of lower jaws, and the remains of 14 or more skulls; but of the rest of the skeleton little was known. The skulls had been damaged apparently to extract the brains—in all cases the surrounding of the foramen magnum was damaged and was the only part of the skull that could not be reconstructed; the long bones had been broken presumably to extract and eat the marrow (*see* WEIDENREICH, FRANZ). The industry associated with the bones consisted of crude tools, largely of quartz. Layers of ashes showed that *Sinanthropus* also used fire (*see* FIRE: *Early Control of Fire*).

The thick skull of Peking Man is typically long and low with a prominent continuous supraorbital ridge and a cranial capacity of about 915 to 1,225 cc. Dentition is robust, the pattern of the molars being complicated by secondary wrinkles; chinless lower jaws show strong sexual dimorphism. Body height is estimated as about 5 ft. for the males and 4¾ ft. for the females.

Black (1932) pointed out the close relationship between *Sinanthropus* and *Pithecanthropus erectus* from Java, and contemporary scholars commonly use the term *Pithecanthropus pekinensis* or even *Pithecanthropus erectus pekinensis*, putting *Sinanthropus* into the same genus as Java Man, now often called *Homo erectus pekinensis* (*see* PITHECANTHROPUS; MAN, EVOLUTION OF: *Pithecanthropus*).

Weidenreich, *The Skull of Sinanthropus Pekinensis* . . . (1943); popular treatments include M. Boule and H. V. Vallois, *Fossil Men* (1957), and R. Moore, *Man, Time, and Fossils*, rev. ed. (1961) (G. H. R. v. K.)

SINCLAIR, a celebrated Scottish family, members of which have held the titles of jarl of Orkney and earl of Caithness. The name is a variant of Saint Clair. SIR WILLIAM SINCLAIR (*c.* 1260–*c.* 1303), younger son of Robert, comte de St. Clair of Normandy, married Amicia, apparently heiress of the barony of Roslin, and the descendant of a line of barons, one of whom (traditionally also of St. Clair descent) obtained Roslin from Malcolm III in the 11th century. Sir William was a leader of the Scots in their war against the English. His grandson SIR WILLIAM SINCLAIR of Roslin (d. 1330) was killed by the Moors in Spain with Sir James Douglas ("the Good"), who had set out to take the heart of Robert I the Bruce to the Holy Land. His son SIR WILLIAM (d. *c.* 1358) married Isabella, daughter of Malise, earl of Strathearn, Caithness, and Orkney, and their son SIR HENRY (d. *c.* 1400) as heir was confirmed in the jarldom of Orkney by Haakon VI, king of Norway, in 1379. He conquered the Faeroe Islands and rediscovered Greenland with the Venetian travelers Niccolò and Antonio Zeno.

Henry's grandson WILLIAM (d. *c.* 1480), 3rd jarl of Orkney of his line, a lord of Parliament as Lord Sinclair (*c.* 1449) and

chancellor of Scotland (1454–58), was created earl of Caithness in 1455. He was celebrated as a patron of the arts and in 1446 founded the collegiate Church of Roslin—"Roslin Chapel." In 1468 Norway ceded the Orkney Islands to James III of Scotland who in 1470 forced William to exchange all his rights there for Ravenscraig Castle, in Fife, and he retained thenceforth only the title of earl of Caithness. In 1476 he disinherited his eldest son, WILLIAM (d. 1487) "the Waster," and settled the earldom on WILLIAM (d. 1513), 2nd earl, the second son of his second marriage, who was killed at Flodden, and the Roslin estate on SIR OLIVER, the first son of his second marriage. By an agreement (1481) with Oliver, William "the Waster" received Ravenscraig castle and fief, renouncing all interest in Roslin. From Sir Oliver descended the house of Sinclair of Roslin, whose direct line ended in 1778.

GEORGE (*c.* 1526–1582), 4th earl of Caithness, grandson of the 2nd earl, was a supporter of Mary Stuart, queen of Scots. Chancellor of the jury which acquitted the earl of Bothwell of the murder of Henry, Lord Darnley, in 1567, he maintained great state in Girnigoe Castle, where he starved to death his eldest son JOHN (d. *c.* 1578). John's son GEORGE (1566–1643), 5th earl, was outlawed for deeds of violence, fled to Shetland, and was succeeded by his great-grandson GEORGE (d. 1676), 6th earl. Heavily in debt, he settled his estates in 1672 on a creditor, Sir John Campbell of Glenorchy (later earl of Breadalbane), who got himself created earl of Caithness in 1677. But in 1681 the privy council decided for a grandson of the 5th earl, GEORGE SINCLAIR (d. 1698) of Keiss, 7th earl. The title then passed to JOHN (d. 1705), 8th earl, grandson of James Sinclair of Murchil, brother of the 5th earl. His son ALEXANDER (*c.* 1684–1765), 9th earl, was last peer to take his seat in the Scots Parliament.

WILLIAM SINCLAIR (d. 1779) of Ratter, a descendant of Sir John Sinclair of Greenland, the third brother of the 5th earl, succeeded as 10th earl, but on the expiry of the Ratter branch in 1789, SIR JAMES SINCLAIR (1766–1823) of Mey, 7th bart., a descendant of George Sinclair of Mey, third son of the 4th earl, became 12th earl. On the death of his great-grandson GEORGE PHILIPS ALEXANDER (1858–1889), 15th earl, Barrogill (or Mey) Castle passed from the family and JAMES AUGUSTUS (1827–1891), 16th earl, descending from Robert Sinclair of Durran, third son of the 1st bart. of Mey, inherited the earldom. From him is descended MALCOLM IAN (1948–), 20th earl, and chief of clan Sinclair.

The line of Lords Sinclair derives from the 1st earl's eldest son WILLIAM "the Waster." His son HERNY (d. 1513), 3rd lord, received parliamentary ratification of his title in 1489. JOHN (1610–1676), 9th lord, got a resettlement on the sons of his only daughter Catherine, mistress of Sinclair, and failing them on the heirs male of her husband, John St. Clair of Herdmanston. Under this, on the death of her son HENRY (1660–1723), 10th lord, and his two sons (of whom JOHN, master of Sinclair, was attainted as a Jacobite in 1715), the right passed to a "stranger in blood" CHARLES ST. CLAIR (1692–1775) of Herdmanston, *de jure* 11th lord, to whose grandson CHARLES (1768–1863), 13th lord, the peerage was restored in 1782. The present holder CHARLES MURRAY KENNEDY ST. CLAIR (1914–), 17th lord, is descended from him.

Sir James Erskine (1762–1837), of Alva, 6th bart., grandson of Catherine, second daughter of the 10th lord and Sir John Erskine of Alva, 3rd bart., inherited the Roslin estate in 1789 as heir of entail, assumed the name St. Clair-Erskine, and in 1805 became 2nd earl of Rosslyn. The earldom had been created in 1801 for the lord chancellor Sir Alexander Wedderburn (maternal uncle of Sir James) with a special remainder in an heir of entail in the Roslin estate. From Sir James are descended the earls of Rosslyn.

See R. A. Hay, *Genealogie of the Sainte Claires of Rosslyn* (1835). (T. I.)

SINCLAIR, UPTON BEALL (1878–), U.S. novelist and polemicist, author of *The Jungle*, a landmark among naturalistic, proletarian novels. Sinclair's fiction was largely topical in nature and in the U.S. most of his books did not survive their occasion; but they were widely translated and continued to be read in other countries. Born in Baltimore, Md., on Sept. 20, 1878, he graduated from the College of the City of New York in 1897 and did graduate work at Columbia University, supporting himself by various journalistic endeavours. *The Jungle* (1906), his sixth novel and first popular success, was written when he was sent by the Socialist weekly newspaper *Appeal to Reason* to Chicago to investigate conditions in the stockyards. His report, cast in fictional form, tells the story of a family of Lithuanian immigrants employed in the stockyards; the chief character, Jurgis Rudkus, the sole member of the family not completely destroyed by the environment, eventually finds some hope for a better life through membership in the Socialist Party. Intended to create sympathy for the workers, *The Jungle* rather ironically aroused indignation at the quality of processed meat, and thus helped bring about passage of food inspection laws; as Sinclair said at the time, "I aimed at the public's heart and by accident I hit it in the stomach." (*See* also MUCKRAKERS.)

A long series of other topical novels followed, none as popular as *The Jungle;* among those of some lasting interest may be mentioned *Oil!* (1927), on events of the 1920s, and *Boston* (1928), on the Sacco-Vanzetti case. Sinclair again reached a wide audience with the Lanny Budd series, 11 contemporary historical novels beginning with *World's End* (1940).

Sinclair ended his activity in the Socialist Party in 1933 by organizing the EPIC ("End Poverty in California") movement; in 1934 he was defeated as Democratic candidate for governor. Of his autobiographical writings, *American Outpost: a Book of Reminiscences* (English title, *Candid Reminiscences: My First Thirty Years;* 1932) was reworked and extended in *The Autobiography of Upton Sinclair* (1962); *My Lifetime in Letters* (1960) is a collection of letters written to Sinclair.

SIND, a region of West Pakistan lying east and southeast of Baluchistan and south of the Punjab. It consists mainly of the alluvial plain formed and watered by the Indus River, but also includes, westward, Kohistan—the uplands north of Karachi—and the fringe of the Kirthar Range, and, eastward, the Registan or Thar Desert, extending from the Nara Channel into Indian Rajasthan. Politically it comprises the Khairpur and Hyderabad divisions, the former consisting of the districts of Jacobabad (formerly Upper Sind Frontier), Sukkur, Larkana, Nawabshah, and Khairpur, and the latter the districts of Hyderabad, Tatta, Dadu, Thar Parkar, and Sanghar. Total area 57,114 sq.mi. (147,925 sq.km.). Pop. (1961) 6,424,668.

The movements of population following the 1947 partition of India led to the influx into Sind of large numbers of refugees who were gradually absorbed into the population. By 1961 Hindus, who at one time formed about one-quarter of the population, numbered less than one-tenth. The prevailing language is Sindhi, but Rajasthani, Baluchi, Punjabi, and Gujarati are also spoken. In Karachi, Hyderabad, and Jacobabad, Siraiki, a dialect of Sindhi, is found.

Soil, Vegetation, and Climate.—A large area of the region is covered by fine fertile alluvium, which becomes coarser toward the north, where it retains moisture better and is easier to plow; the south rarely yields such rich harvests. All parts of the region are liable to the deposition of salt, which so reduces fertility that land seriously infested is useless, the worst effects being observed in the fine-textured soils of southern Sind. Many parts have also become waterlogged. Almost the whole of the central plain from the Panjnad to the Arabian Sea is marked by the changes in the courses of the Indus or its distributaries. The silt deposited by the Indus in its bed has raised its level in many parts above the surrounding country and there are artificial embankments on either side. The soil is fertile. Canals from the Lloyd (Sukkur) and Ghulam Muhammad barrages serve 7,500,000 ac. (3,035,250 ha.), producing good crops of wheat, rice, and cotton. Gudu barrage, which was under construction in upper Sind in the mid-1960s, commands a cultivable area of 2,500,000 ac. (1,011,750 ha.). There are areas in the northwest which are too high to be irrigated by flow from flood canals, and are clothed with scrub. Parts of the flood plain are covered with forests.

Aridity limits forest to about 1,200 sq.mi. (3,108 sq.km.) near the Indus from Ghotki to the mid-delta. Babul (*Acacia arabica*) is most characteristic in lower Sind and yields fuel and timber for boats. Its bark is used for tanning and the leaves and pods as fodder for camels and goats. Kandi (*Prosopis spicigera*) provides fuel and fodder.

The climate is arid and extreme. The winters are mild and the summers very hot, the temperature frequently rising to 45.5° C (114° F) and occasionally to 49° C (120° F). The mean maximum temperature for June for Jacobabad is 45.5° C, with an absolute maximum of 53° C (127° F), the highest recorded in the subcontinent. Rainfall is both scanty and irregular, the mean annual for Hyderabad being 9 in. The climate of the coastal strip is equable and humid.

History.—Excavations at Mohenjo-Daro, 180 mi. northeast of Karachi, have revealed the remains of a large city which existed between 2500 and 1500 B.C., and whose inhabitants enjoyed a high degree of civilization. Sind was invaded by Alexander the Great in 325 B.C. On his death two years later it passed to Seleucus I Nicator, who yielded it in 305 to Chandragupta, the founder of the Maurya dynasty. After a phase of Buddhist influence under Asoka, Chandragupta's grandson, there were incursions from the west and north. A Sudra dynasty with its capital at Aror (Alor) was followed by a period of Brahman rule (7th century A.D.). In 712 Sind was conquered by the Arabs and for nearly three centuries was nominally subject to the Arab caliphs. Though conquered by Mahmud of Ghazni (11th century), Sind long remained semi-independent under local Muslim dynasties, and it was not till the time of Akbar (16th century), who was born at Umarkot in Sind, that the province was incorporated into the Mogul Empire. When that empire broke up on the death of Aurangzeb (1707), local dynasties again arose. The Talpurs, of Baluch descent, were ruling Sind under the title of mirs, with their capital at Hyderabad, when during the First Afghan War (1839–42) the British army marched through the territory, using it as a base for its operations against Afghanistan. The mirs were compelled to accept a treaty by which they paid a tribute to Shah Shuja of Afghanistan, surrendered the fort of Bukkur to the British, and allowed a steam flotilla to navigate the Indus. In 1842 Sir Charles James Napier (*q.v.*) arrived in Sind and fresh terms were imposed on the mirs. The Baluch army resented this loss of independence and attacked the British residency near Hyderabad. After two decisive victories by Napier, Sind was annexed to British India as part of the Bombay Presidency. In 1936 it became a governor's province and in the following year it was constituted an autonomous province. After the creation of Pakistan in 1947 it again became a governor's province. In 1948 Karachi and its suburbs were separated from Sind and the seat of the province was shifted to Hyderabad. When West Pakistan was consolidated into a single province in 1955, the separate Sind government ceased to exist, and the region was divided between the two divisions of Hyderabad and Khairpur.

SINDBAD THE SAILOR, a hero in the *Thousand and One Nights* (*q.v.*), who recounts his adventures on seven voyages. These are based on the experiences of navigators, probably in the early Abbasid period (*c.* A.D. 750–850). Fortunes were made by merchants of Basra trading with the East Indies and China; but the risks were great. In these stories, the dangers are exaggerated by a strong infusion of the miraculous which offers parallels with the earlier literature of several nations.

The stories follow a pattern. Sindbad sails from Basra with merchandise. He is marooned or shipwrecked, and encounters terrible dangers which he only survives by a combination of resourcefulness and luck. He finally returns home with a fortune. On the sixth voyage, he reaches Sarandib (Ceylon). The king gives him presents to take back to the caliph, Harun al-Rashid, in Baghdad. In the Calcutta text of the *Nights*, the normal seventh voyage is replaced by the story of how the caliph induces him to go back to Ceylon with return gifts for the king.

Considerable light is shed on seafaring and trade in the East. For example, though Sindbad does not specify the goods which he takes from Basra, it is stated that he obtains diamonds and other precious stones, sandalwood, camphor, coconuts, cloves, cinnamon, pepper, aloes, ambergris, and ivory during his voyages. Among the natural hazards of seafaring, the captain loses his course on the third and sixth voyages. The ship is wrecked on the fourth to seventh voyages, though in one case (the fifth voyage), this is due not to storms, but to the fabulous roc (*q.v.*), a bird which drops huge rocks on the ship. In one instance (the third voyage) hairy apes swarm over the ship and leave the crew on an island. Perhaps the activities of pirates are suggested here. In the seventh voyage (Calcutta version), Sindbad and his shipmates are captured by savages in canoes, possibly in the Andamans.

Miraculous hazards include the giant roc bird (second and fifth voyages) whose egg resembles a huge white dome. The whale which is mistaken for an island (first voyage) has parallels with the great whales of Pliny and Solinus. The valley of diamonds (second voyage) has parallels in al-Qazwini (the 13th-century Persian geographer), Marco Polo, and St. Epiphanius, bishop of Salamis in Cyprus (d. A.D. 403). The cannibal giant of the third voyage suggests Cyclops. In the fourth voyage, Sindbad's companions are fattened by cannibals with food which causes them to lose their reason. This calls to mind the lotus-eating of the *Odyssey*. Sindbad's burial in the cavern of the dead is foreshadowed in a reference by St. Jerome to a supposed Scythian custom of burying alive with the dead those who have been dear to them. On the fifth voyage, the "old man of the sea" who compels Sindbad to carry him has been identified with the huge apes of Borneo and Sumatra.

P. Casanova suggests that Sindbad's adventures may have influenced Defoe's *Robinson Crusoe* and Swift's *Gulliver's Travels*. Sindbad the Sailor should not be confused with Sindbad the Wise, hero of the story of the Seven Wise Masters (*q.v.*).

SINDHIA, the name of the Maratha ruling family of Gwalior which for a time in the 18th century dominated the politics of northern India. One branch held the headship of a village near the Maratha capital, Satara, in the 17th century. The founder of the Gwalior house was Ranoji, who was said to have been a personal attendant of the peshwa (title of the hereditary Maratha rulers), Balaji Baji Rao. His military abilities brought him promotion; in 1726 he was sent to Malwa to collect revenue for the peshwa. He died in 1745, having fixed his capital at Ujjain. The Sindhia capital was later moved to the rock fortress of Gwalior.

After Ranoji's grandson's death at the Battle of Panipat in 1761 his illegitimate son Mahadaji succeeded (1761–94). One of the ablest men of his time, he created a north Indian empire, though he always gave nominal allegiance to the peshwa. He emerged from war with the East India Company (1775–82) as the recognized ruler of northwest India. With the aid of French officers he defeated the Rajputs, took the Mughal emperor Shah Alam under protection, and finally won control of the peshwa by defeating Holkar, the peshwa's chief general, in 1793. He died at the height of his fame in 1794.

His grandnephew Daulat Rao, his chosen heir (ruled 1794–1827), was a man of lesser stature. He was worsted by Tukoji Holkar in the struggle for control of the peshwa. He came into collision with the British in 1803, was defeated in four battles, saw his French-trained army broken up, and had to make peace. He lost Delhi and the emperor but retained control of Rajputana until 1817, when Lord Hastings gave him the choice of cooperating against the Pindaris (*q.v.*) or war. He submitted and died in 1827.

The Gwalior State continued intact until India gained independence in 1947. Its territory was incorporated in Madhya Pradesh in 1956. The most distinguished Sindhia of modern times was Sir Madhava Rao Sindhia (1876–1925), who, succeeding in

1886, ruled with vigour and enlightenment for 31 years. *See also* GWALIOR; MADHYA PRADESH.

SINDHĪ LANGUAGE is spoken by about 7,000,000 people (mid-1960s) in the province of Sind, West Pakistan. With Lahndā and Kāshmīrī it belongs to the northwestern group of Indo-Aryan languages (*q.v.*). Sindhī-speaking people are also found in neighbouring districts, in the Rann of Cutch, and in Kathiawar. Many Sindhī-speaking Hindus from Pakistan have migrated to Bombay and other Indian cities, *e.g.* Delhi, Ajmer, Jaipur, and Gwalior.

Linguistically, Sindhī is bounded on the west by the Balōchī (*q.v.*) language, an Iranian language, and by the Lahndā language (*q.v.*), to which it is closely akin, on the north. Of the four dialects of Sindhī, Vichōlī (Hyderabad) is standard, being employed for literary purposes. Another important dialect, Kacchī, is spoken in Cutch, and is strongly influenced by Gujarātī.

Muslim influence, over 1,000 years, gave a large number of Persian and Arabic borrowings, and the written character used for Sindhī is a variety of the Persian, with necessary modifications for sounds peculiar to the language; Hindus use a form of Devanāgarī.

Phonology.—The Sindhī system corresponds, in general, to that of Indo-Aryan. It shares one peculiarity with Kāshmīrī, viz., instead of a single final consonant, it has the consonant plus a voiceless vowel—for example, *chōkar*ᵘ "boy" and *chōkar*ᵉ "girl." Another feature is the series of "recursive" consonants, transcribed $\bar{g}$, $\bar{j}$, $\bar{ḍ}$, $\bar{b}$ (or *gg, jj, ḍḍ, bb*), which are pronounced by drawing in (instead of expelling) the breath, with the larynx lowered and the glottis closed. These may occur initially. Still another feature is the occurrence of cerebrals where dentals are found in other Indo-Aryan languages. (*Cf.* Sindhī *ḍ̄iaṇ* and Hindī *dēnā* "give.")

Morphology.—Sindhī has two genders, masculine and feminine, and two numbers, singular and plural. Generally, case relationship is indicated by means of postpositions added to the oblique forms. An adjective agrees in gender, number, and case with its noun. Sindhī, like Lahndā and Kāshmīrī, uses pronominal suffixes attached, as in Lahndā, to nouns as well as participial forms, while in Kāshmīrī they are used only with verbs.

The Sindhī verb has two conjugations, intransitive and transitive. Compound tenses consist of combinations of participles plus auxiliary. (For Sindhī *see* the *Linguistic Survey of India*, vol. viii, pt. i, 1919.)

Literature.—Until recently little Sindhī literature had been printed; activity quickened during the 1920s with the formation of literary societies and availability of publishing outlets. The Sindi Sahitya Mandal (Sindhī Literary Circle) was founded in 1949 in Bombay; others are active in other Sindhī cities.

SINGAPORE, an independent sovereign republic, a member of the United Nations and of the Commonwealth of Nations, includes one main island and many small islands lying at the southern end of the Malay Peninsula, with which it is connected by a rail and road causeway (¾ mi. [1 km.]) across the Johore Strait. Singapore Island, bounded south by the Singapore Strait, is roughly diamond shaped, 26 mi. by 14 mi. (42 km. by 23 km.), with an area of 209.6 sq.mi. (543 sq.km.) and a midpoint of latitude 1°22′ N, longitude 103°50′ E. The approximately 40 small islands total 15 sq.mi. (39 sq.km.).

SINGAPORE

Singapore owes much of its wealth and continued prosperity to its focal position in Southeast Asia on international sea and air routes. Its strategic position and deepwater harbour have enabled the city of Singapore (*q.v.*) to become the largest port in Southeast Asia, the natural outlet for the products of the Malay Peninsula, and one of the world's greatest commercial centres. The island also serves as an important naval and air base.

PHYSICAL CHARACTERISTICS

An outlier of rocks and structures running through the Malay Peninsula, Singapore has a central granite zone culminating in Bukit ("hill") Timah (581 ft. [177 m.]), west of which Triassic quartzites and shales dip to the southwest and form low degraded scarps which are heavily eroded into hills aligned in a northwest-southeast direction with the steepest ridge behind Pasir ("sand") Panjang. East of the granite zone lies a mass of weathered detritus averaging 100 ft. (30 m.) in height. Weathered red and yellow lateritic soils and thick iron pan cap all rocks. A quarter of the island is lower than 25 ft. (8 m.). Only Pasir Panjang has a steep coast.

The deepwater channel of Keppel Harbour is sheltered from the south by the hilly islands of Blakang Mati and Brani. Elsewhere the coast is silting, and dangerous coral reefs and sandbanks lie offshore. At the eastern end of the Johore Strait is a deep scoured channel, which permits large vessels to approach the naval dockyard at the northern corner of Singapore Island. The solid causeway across the strait prevents the through movement of vessels and hastens silting at the western end.

On the central granite hills of Singapore Island is the only remnant of its forest, a stand of dense, mixed evergreen trees which protects three reservoirs formed by damming small streams. They are now inadequate for the island, and water is piped from south Johore. The climate is equatorial, with temperatures throughout the year varying a few degrees either side of the 28° C (82° F) mean. There is no well-defined wet or dry season, and the annual rainfall of 95 in. (2,413 mm.) is evenly distributed throughout the year. Prevailing winds are from the northeast from November to February and from the south during May to August, but strong daily land and sea breezes maintain agreeable physiological conditions. Heavy rains and high seas come during the northeasterlies, from which the harbour is well protected. (E. H. G. D.)

HISTORY

Malay tradition confirms that the first colonizer of Singapore was a prince from Palembang, the Sumatran capital of the empire of Sri Vijaya. It may have been the Chola (*q.v.*) ruler Rajendracola Deva I (1016–44) who named the settlement Singapore ("city of the Singhs" or "lions"). He almost certainly attacked the island in 1025 during his descent on Sri Vijaya and its colonies.

There was another Chola raid in 1068. In Javanese inscriptions and Chinese records down to the end of the 14th century the commoner name for the island is the Javanese Temasek or Tumasik from *tasek*, "sea." In 1275 the Javanese king Kritanagara, when he raided Pahang, probably attacked Temasek. According to a Chinese traveler, Wang Ta-yuan, just before 1349 about 70 Siamese war boats besieged Temasek for a month but had to withdraw. A Javanese work, the *Nagarakritagama*, written in 1365, includes Temasek among the conquests of the Javanese empire of Majapahit.

At the end of the 14th century, Temasek fell into decay and was supplanted by the port of Malacca. Yet in 1552 it was still a port of call from which St. Francis Xavier dispatched letters to Goa, and João de Barros, in the *Décadas da Asia* (published 1553), describes it as "a resort not only of Indian shipping but of traders from China, Siam, Champa, Cambodia, and the Malay Archipelago."

East India Company.—On Jan. 28, 1819, Sir Thomas Stamford Raffles (*q.v.*) of the East India Company, searching for a factory site, forestalled by the Dutch at Riouw (Riau, Rhio), and, having found the Carimon Islands unsuitable, landed at Singapore. He found only a few Chinese planters, some aborigines, and a few Malays, and was told by the hereditary chief, the *temenggong* (direct ancestor of the sultans of modern Johore), that there were no Dutch there and that the company could purchase land. The *temenggong*, however, was a subordinate of his cousin Abdul Rahman, sultan of Riouw, Lingga, Pahang, Johore, and Singapore, who was under Dutch surveillance. Abdul Rahman was a younger son and not a sultan *de jure*. Raffles, disobeying instructions not to offend the Dutch, withdrew his own recognition of Abdul Rahman as sultan of Singapore and installed Abdul Rahman's elder brother, Husain, to validate the purchase of land there on behalf of the company. The Dutch protested. In London the court of directors, though it decided Raffles had contravened instructions, took no action.

In 1824 an Anglo-Dutch treaty left Malaya and Singapore in the British sphere, and on Aug. 2 the whole of Singapore Island was ceded to the British for a money payment. In 1826 Singapore, Penang, and Malacca were combined as the Straits Settlements to form an outlying presidency of India. In 1830 they were reduced to a residency under Bengal, and two years later Singapore became their capital. When the East India Company lost its monopoly of the China trade (1833) it also lost its interest in Malaya. The settlements were transferred to the direct control of the governor-general of India in 1851. In 1867 they were made a crown colony under the Colonial Office.

Development of the Port.—Meanwhile, the trade of Singapore had suffered from British development after 1842 of a rival port, Hong Kong, as later it was to suffer from the French occupation of Indochina, the development of Saigon and Haiphong, and from the establishment of Dutch ports and shipping lines in the Netherlands East Indies. With the opening of the Suez Canal in 1869 and the advent of steamships, however, an era of prosperity began that led eventually to the construction of three miles of wharves at Tanjong Pagar and finally in 1921 to a naval base. The economic growth of the Malay states after they became British protectorates enlarged transit trade. (R. O. WT.)

It was the demand of the industrial West for tin and rubber that made Singapore one of the greatest ports in the world. After World War I steps were taken to modernize Malayan defenses and, with the lapsing of the Anglo-Japanese alliance, to build a large naval base in Singapore.

World War II.—In World War II the Japanese landed in Kelantan and Thailand on Dec. 7, 1941 (Dec. 8 west of Hawaii). By the end of January 1942 they had overrun the peninsula and were opposite the island of Singapore. The sinking of the battleship "Prince of Wales" and the battle cruiser "Repulse" had given them command of the sea, and a superior air force covered the advance down the peninsula. The Japanese crossed the Johore Strait on Feb. 8, 1942, and the British command surrendered the island and city on Feb. 15. Singapore remained in Japanese occupation until September 1945.

Political Developments after the War.—British political plans for Malaya excluded Singapore from the Malay Union and later the Federation of Malaya (*see* MALAYSIA: *History: Malaya*) mainly because Singapore's predominantly Chinese population would be a racial obstacle to a common citizenship. As a separate crown colony (from 1946) Singapore made constitutional progress despite the Communist insurrection in Malaya. Elected ministers and a Legislative Assembly with an elected majority assumed government responsibility in 1955, except for defense and foreign affairs. In 1959 the official and nominated elements were eliminated and Singapore became self-governing, although Britain still retained control of defense and foreign affairs.

Singapore joined the Federation of Malaysia on its formation in September 1963, retaining autonomy in education and labour and accepting in consequence a smaller number of seats in Parliament. The ruling People's Action Party (PAP) led by Lee Kuan Yew had refused in 1959 to form a government until eight extreme left-wing leaders who had been detained by the colonial authorities were released. This left wing opposed the concept of Malaysia, broke away to form the Barisan Sosialis Party, and was accused of being a Communist Front organization amenable to the control of the Indonesian Communist Party. The PAP faced fresh dangers of subversion when Indonesian opposition to Malaysia took the form of military and economic "confrontation" (1964). There were a number of bomb outrages and attempts to blow up military installations and public utilities; the suspension of Indonesian trade reduced the gross national product by 8%.

"Confrontation" ended in June 1966, but Singapore had left Malaysia in August 1965, invited to do so by the Malaysian government as a result of political friction between the state and central governments. This conflict had racial undertones, and it continued to affect relations between independent Singapore and Malaysia.

POPULATION

At the census in 1957 Singapore's population numbered 1,445,929, comprising 1,090,596 Chinese (75%), 197,059 Malays, 124,084 Indians and Pakistanis, 11,382 Eurasians, 10,826 Europeans (excluding servicemen), 5,426 Ceylonese, and 6,556 others. The estimated population in December 1966 was 1,945,000 (a density of 9,262 per square mile), largely a natural increase although assisted by some migration from West Malaysia. Over half the population was under 15 years of age. When Raffles founded the British settlement in 1819 fewer than 200 people lived on the island. Five years later there were over 10,000; by 1860 half the population of 82,000 was Chinese; and by 1931 the Chinese formed 75% of the population of 559,945. For many decades Singapore was a "frontier town," its population largely migratory and the women vastly outnumbered. When the first immigration quotas were imposed in 1932 there were no restrictions on women immigrants. Since World War II the policy has been increasingly selective and there is now virtually no immigration.

ADMINISTRATION AND SOCIAL CONDITIONS

When Singapore became a republic in 1965 Tun Yusuf bin Ishak, the head of state (*yang di-pertuan negara*), became president; Lee Kuan Yew remained prime minister. The president is elected by Parliament for a term of four years. The prime minister and nine other ministers form the Cabinet, which is responsible to an elected Parliament of 51 members. Voting is compulsory. There are no local government bodies. Appointments to the civil service are made by an independent Public Services Commission. Criminal and civil jurisdiction is exercised by the High Court, consisting of the chief justice and six judges. There are two civil district courts; 15 district and magistrates' criminal courts; and a juvenile court. The Shariah Court has jurisdiction in matters of Islamic law. There is a Federal Court of Appeal, and in certain cases further appeal to the Judicial Committee of the Privy Council in London is possible.

The main religions are Islam, Buddhism, Hinduism, and Christianity. Malay is the national language, but Malay, Chinese, Tamil, and English are all official languages and English is the

language of the administration.

Labour and Welfare.—Legislation governing working conditions provides in general a 44-hour week and an 8-hour day for manual workers. Employment of women and young persons is regulated, and provision is made for compensation for injury or death at work and for retirement benefits. Labour disputes which cannot be settled by agreement, with the aid if necessary of ministry officials, are adjudicated by two Industrial Arbitration Courts, which also record and supervise agreements reached by collective bargaining. There are about 100 trade unions with a total membership of 160,000. The Social Welfare Department has charge of public assistance.

The Woman's Charter, which came into effect in 1961, enforced monogamy, made marriage registration compulsory (these provisions do not apply to Muslim marriages), and raised the marriage age from 16 to 18. The validity of existing polygamous marriages was not affected. The charter also regulates divorce.

Housing.—The whole area within six miles of the Singapore River, which runs through the heart of Singapore city, is built over —a mixture of congested streets and covered five-foot ways, modern office and apartment buildings, and shopping districts and residential suburbs in which old-style colonial bungalows survive. About 500,000 people in Singapore Island live in the Housing and Development Board's apartment buildings. During 1935–59 the Singapore Improvement Trust built 23,019 homes and shops. Between 1960 and 1965 the Housing Board added 54,430 units. Another 60,000 units were being built under the 1966–70 plan. Some 2,000 ac. (809 ha.) were being reclaimed at Kallang basin and between Bedok and Tanjong ("cape") Rhu, on the south coast, for the siting of light industries and rehousing under the urban renewal plan. This plan also involved clearing the crowded and dilapidated 100-year-old shop-houses and two-storied buildings in some of the older parts of Singapore city.

Health.—In the mid-1960s the state supported 11 hospitals with 7,000 beds. They included a large general hospital, a district hospital, an orthopedic hospital, and specialist hospitals for mental and infectious diseases, including tuberculosis and leprosy, and an opium-addict treatment centre on St. John's Island, in the straits. Five private hospitals have 750 beds. The Health Institute houses the school health services and the university's Department of Social Medicine and trains health officers. Physicians, dentists, and pharmacists are trained in the University of Singapore. Between 1947 and 1965 the birth rate fell from 45.9 per 1,000 population to 29.9; the infant mortality rate from 81.3 to 26.3; and the death rate from 13.3 to 5.5, one of the lowest in the world.

Education.—Since the population of Singapore is so youthful, one in four attends school and education absorbs one quarter of the republic's annual expenditure. All children receive six years' free primary education, and the Malays enjoy free education to university standard. Half a million pupils follow a common syllabus designed to foster a national consciousness. This is also furthered by a number of integrated schools, which about 19% of the pupils attend. Another 43% are in English-language schools, 32% are taught in Chinese, 5% in Malay, and 1% in Tamil. Most children are at least bilingual. The emphasis of the second five-year plan was to ensure that after 1966 every child who qualified had the opportunity of secondary education. The University of Singapore had approximately 3,000 students in the mid-1960s; Nanyang University, founded in 1953 largely by Chinese subscriptions, had over 2,000; and the Singapore Polytechnic had 2,300, 950 of them full-time.

Defense.—Singapore's armed forces consist primarily of two battalions of infantry with an ancillary artillery unit and supporting forces. A new form of national service is being introduced. All are liable. Ten percent of the men will be selected for full-time two years' service, forming two infantry battalions which will replace the Defense Force units. The remainder will be liable for 12 years' part-time service. Singapore is also the main base for British Navy, Army, and Air Force units in the Far East. This arrangement was preserved after Singapore seceded from Malaysia, with which Singapore has a defense agreement. Over 30,000 civilian workers are employed at the British bases.

Political Parties.—In 1966 the PAP led by Lee Kuan Yew, the prime minister, held 42 out of 51 seats in Parliament. Before the end of the year the Barisan Sosialis Party, which had won 13 seats in the general election in 1963, boycotted all parliamentary proceedings. Its remaining M.P.s then resigned. In 1966 the Singapore United Malay National Organization (UMNO), a branch of the Malaysian UMNO, sought to establish itself as a separate party.

THE ECONOMY

Trade.—Singapore was founded as a free port, open to the ships and traders of every country, at a time of monopoly trading in many parts of the Far East. It remained a free port for 140 years. Until the late 1950s there were no import duties except on petroleum, tobacco, and liquors. The rapid growth of the population and the changing prospects for trade, as neighbouring countries developed their economies, then turned Singapore's attention to industry, and the first protective duties were imposed. Nearly two-thirds of the $944,000,000 spent on the 1961–65 development plan was devoted to economic development, and the $1,521,000,000 of the 1966–70 plan put the same emphasis on an industrial substructure. (Currency, quoted here and following, is in Singapore, not U.S., dollars.) The continuing importance of the entrepôt trade was recognized, however, by the provision of free trade zones and by the general absence of customs formalities in the importation of commodities which are processed for reexport. Manufactured goods, machinery, and foodstuffs form the other half of this entrepôt trade. Singapore is the world's largest rubber market and exporter, although producing practically no rubber itself.

In the 1960s Singapore's external trade averaged $7,500,000,000 yearly, with an unfavourable balance of $700,000,000. There was a setback when trade with Indonesia was broken off during "confrontation," but the figures began to rise again in 1966. The part played by the entrepôt trade in Singapore's economy is well illustrated by the fact that the gross national product, which per capita is the second highest in Asia, is less than half the value of the island's foreign trade. Singapore handles or transships a great deal of Malaysia's trade. Its principal overseas customers are the United Kingdom, the U.S., Japan, and Hong Kong; chief suppliers are the U.K., Japan, China, and Australia.

Agriculture and Fisheries.—Vegetables are cultivated intensively in parts of the island. Coconuts, fruit, tapioca, tobacco, and pepper are grown mostly on family smallholdings. Larger holdings are usually mixed farms, for raising poultry and pigs as well as vegetables. There are substantial exports of pork, poultry, and eggs. About 10,000 tons of fish are landed, from coastal waters, palisade fish traps, and fish ponds.

Industry.—Encouragement of industry is the responsibility of an Economic Development Board which manages the industrial estates, provides technical and financial assistance, and takes part in joint ventures with private investors. The largest project is the Jurong estate, of 9,000 ac. (3,642 ha.), to the west of Singapore city. It has sites for heavy and light industries, adequate power and water, access roads, a spur railway, and its own harbour. The centre of this complex is the National Iron and Steel Mill, with associated shipbuilding and structural steel interests, and a planned blast furnace capacity of 300,000 tons of steel a year. Five smaller industrial sites include a reservation for boatbuilding and marine industry. By the end of 1966 more than 150 firms had been granted pioneer certificates, entitling them to tax remissions and other privileges extended by the government to new industry. These enterprises ranged from petroleum refineries, flour mills, and chocolate and textile manufactures, to the assembly of motor vehicles and manufactures of metal, soap and toilet preparations, industrial chemicals, tires, and condensed milk.

Shipping and Transportation.—Over 23,000 ships, of a registered 100,000,000 tons total, annually enter and clear the port of Singapore. Singapore is also a bunkering port and, as a blending and distributing centre, handles 10,000,000 tons of oil a year. A great deal of the general cargo is unloaded from vessels anchored in the roads. Telok ("bay") Ayer basin is reserved for small boats engaged in the barter trade with Indonesia. The terminus

of Malayan Railways is linked to the harbour services.

Sixteen major airlines operate regular services from, or through, Paya Lebar airport, 7½ mi. [12 km.] NE of the city centre. There are 525 mi. (844 km.) of roads, and the causeway over the Johore Strait links the island with peninsular Malaysia. Island-wide motorbus services are the main form of public transport, but 3,000 trishaws survive, and the taxis are supplemented by "pirate" cars which act as minibuses and are used especially by schoolchildren and office workers.

Power.—For power the island depends on thermal-generated electricity from two power stations with an output of over 1,000,000,000 kw-hr. in 1966. Another power station comprising four 60-megawatt units was to be completed by 1970. Much of Singapore's water is drawn from Johore.

Communications.—Radio and television services in the four official languages and additional dialects are operated by the government. There are three English-language daily newspapers, three Chinese, two Malay, and two Tamil. Singapore has extensive radiotelephone communication and a public teleprinter service with most parts of the world. The SEACOM cable provides high-quality telephone circuits with Jesselton and Hong Kong.

Finance.—Singapore and Malaysia have a common banking system and until June 1967 had a common currency (*see* MALAYSIA: *The Economy: Trade and Finance*). Government revenue in 1967 was estimated at $590,500,000 (Singapore, not U.S., dollars) and expenditure at $590,200,000. Expenditure included the municipal services, which were mainly financed by a property tax (rates). Income and company tax and customs and excise duties were the principal national taxes, the protective duties, not imposed till the late 1950s, making as yet only a small contribution. Only 7% of the working population paid income tax. There were 34 commercial banks, the assets of which at the beginning of 1966 totaled $2,382,000,000. *See* also MALAYSIA.

SINGAPORE (city), the capital of the Republic of Singapore (*q.v.*), lies at the southern end of the diamond-shaped island of Singapore, at the narrow gateway between the Indian Ocean and the South China Sea. Created a city by royal charter in 1951, Singapore was administered as a municipality by an elected mayor and fully elected council from 1957 to 1959. In 1959, when the colony of Singapore became internally self-governing, administrative responsibility for the city was assumed by the state.

The town, founded by Sir Thomas Stamford Raffles (*q.v.*) in 1819, was centred on the landing place he used near the mouth of the Singapore River. Within three weeks the resident in charge reported that "inhabitants are flocking in from every quarter." The commercial possibilities and the strategic value of the settlement were such that progress was uninterrupted even after the British acquisition of Hong Kong deprived it of some of its trade. The opening of the Suez Canal in 1869 increased its importance, and as steam replaced sail Singapore became a bunkering station. Keppel Harbour was developed in the early 20th century, but the old anchorage in the roads has remained in use, providing the city with one of the world's most fascinating waterfronts.

In the older part of the city are grouped the principal government and public buildings, the Supreme Court, banks and commercial offices, and St. Andrew's Cathedral, built by convict labour. The famous Botanic Gardens are three miles north of the city centre, close to the University of Singapore. The government maintains a national museum and library, a national theatre, and an aquarium all within the city area of approximately 37 sq.mi. (96 sq.km.). The estimated population in 1966 was 1,200,000, but separate city statistics had ceased to be available and an extensive building program was changing both the face of the city and the distribution of population. After World War II multistoried buildings dotted the waterfront skyline, and redevelopment after 1960 saw slum areas replaced by tall apartment buildings and modern housing developments complete with shopping arcades, schools, playgrounds, and other amenities. Much of picturesque "Chinatown" remained, but this too was changing. (A. KE.)

SINGER, ISAAC MERRIT (1811–1875), U.S. inventor who developed the first practical domestic sewing machine and brought it into general use, was born on Oct. 27, 1811, in Rensselaer County, N.Y. In 1851 he developed and patented a sewing machine which embodied a spring presser foot and feed synchronous with the needle action and thus permitted continuous and curved stitching. An overhanging arm projecting the needle bar over the work, which was spread over a horizontal table, made it possible to sew on any part of the work. Singer's machine was the first that could perform these necessary functions, and its basic design features have been followed in almost all subsequent machines. Nonetheless, Elias B. Howe (*q.v.*) must be credited with the first employment of the basic eye-pointed needle and lock stitch (in 1846), which, since Singer had embodied these in his machine, resulted in Howe's winning an infringement suit against Singer in 1854. The suit did not prevent Singer from manufacturing his machine, however, and in June 1851 he formed a partnership with Edward Clark, their company becoming, by 1860, the largest producer of sewing machines in the world. Singer left commercial development of his invention to Clark while he supervised manufacturing and the "experimental department," where he perfected other improvements. In 1863 he and Clark formed the Singer Manufacturing Company and Singer retired to England, where he died on July 23, 1875. (A. B. J.)

SINGHBHUM, the southernmost district in the Chota Nagpur division of Bihar, India. Area 5,191 sq.mi. (13,445 sq.km.). Pop. (1961) 2,049,911. Singhbhum forms part of the southern fringe of the Chota Nagpur Plateau and is a hilly upland tract composed largely of crystalline and ancient sedimentary rocks. There is a central 1,000-ft. (300-m.) gneissic and schistose peneplain drained by the Kharkai and Sanjai rivers. This fertile plain is bordered in the northwest and southwest by higher dissected and forested masses of hills with a general elevation of 2,000 ft. above sea level but occasionally rising to 3,000 ft. Toward the east there are dissected and forested hills of lower elevation (*c.* 1,000 ft.), through the centre of which runs the narrow Subarnarekha Valley. Forests occupy about one-third of the district. About one-fourth is cultivated, rice covering 80% of the sown area.

Singhbhum is one of the most important districts of India for metallic minerals. In the extreme south iron ores amounting to half the Indian output are produced from banded hematite-quartzites. Manganese (annual output *c.* 40,000 tons) and chromite (*c.* 3,500 tons) are mined near Chaibasa. Almost the whole of the country's kyanite production comes from Singhbhum, which is also the only district in India where copper (annual output *c.* 400,000 tons) is mined. Among the heavy industries are the iron and steel and allied manufactures at Jamshedpur (*q.v.*) and copper at Maubhandar. Shellac is manufactured at Chandil and Chakradharpur. The largest town is Jamshedpur but the headquarters of the administration are at Chaibasa (pop. [1961] 22,019). Singhbhum is traversed by the Bombay–Nagpur–Calcutta Railway, which passes through Jamshedpur where railway lines from the Damodar coalfields and the iron and copper regions converge. About two-fifths of the population of the district consists of tribal peoples, of whom the most numerous are the Hos and the Santals. (E. AH.)

SINGIDA REGION, TANGANYIKA, established in October 1963 following a reorganization of administrative units in Tanganyika (Tanzania), comprises Iramba, Singida, and Manyoni districts, which previously belonged to the former Central Region. It is bounded north by Shinyanga and Northern (Arusha) regions, and east by Dodoma Region, south by Iringa and Mbeya regions, and west by Tabora Region. Area, 19,050 sq.mi. Pop. (1963 est.) 393,520. The region lies on the central plateau of Tanganyika, its height ranging from 3,000 to more than 5,000 ft., and is a major watershed. Following the southeastern boundary, the Njombe River joins the Rufiji system and the Indian Ocean, whereas in

the southwest drainage is to Lake Tanganyika and the Congo River. Much of the drainage is to dischargeless basins, to the Wembere depression on the northwestern boundary (draining to Lake Eyasi), and to the Bahi Swamp. Mean annual rainfall is mostly less than 30 in., rain falling during November–April, with almost complete drought for six months.

Regional headquarters are at Singida. The main African tribes are the Iramba and Nyaturu (or Turu; in Iramba and Singida) and the Gogo (in Manyoni). The economy is based mainly on livestock, producing hides, skins, and clarified butter. Some areas are infested by the tsetse fly. Beeswax, honey, and gum arabic are collected and there is fishing and salt making in Bahi Swamp. The region is linked by road and by the Central Railway with the interior and the coast. (J. M. Ke.)

SINGING, the oldest form of music making, is an art with many associations, social and literary, as well as musical, and demands treatment, therefore, from both historical and technical viewpoints. It may best be treated in its traditional aspects in the first place, followed by stylistic and technical considerations.

Folk and Oriental Styles.—Of the vast bibliography of man as a music maker, Charles Seeger remarks: "Much of it is of music-hearing man. But little of it is of singing man; and that little is confined nearly entirely to him as a user of one single singing style—that of the *bel canto* of the opera and concert singer in the European tradition of the fine art of music" (*Western Folklore*, vol. xvii, no. 1, 1958).

In the past, differences in singing style were often remarked upon. In the 4th century, to the emperor Julian the Apostate, German singing was like the croaking of birds. A little later, Roman churchmen were complaining of the "beastly" singing of the Franks and Burgundians, who made "horrid clucking noises and crushed the melody to pieces in their throats." A 16th-century German commentator, Andreas Ornithoparcus, remarked (the translation is by the early 17th-century composer John Dowland): "The English doe carroll; the French sing; the Spaniards weepe; the Italians which dwell about the coast of *Ianua* caper with their voices; the other barke; but the Germans (which I am ashamed to utter) doe howle like Wolves." Such distinctions, whose rough justice the modern musical folklorist would in some instances admit, became ignored when, after 1600, a more or less standard manner of voice production imposed itself on the performance of Western art music.

It is only since the advent of mechanical and electronic sound recording that other singing styles than the conventional *bel canto* have come to be acknowledged, though in fact only a small proportion of the world's population practices or even admires this manner of singing. The art musics of the Orient employ quite other singing styles, as do also the various folk musics throughout the world.

The qualities of style that make a performer important in his tradition are differently assessed in different places. Notably, there are the regional variations in preferred ways of producing the voice, such as caught the ear of commentators in the past. For instance, English folk singers tend to pitch their voices high, while in Sardinia a guttural growl is practised. Pygmy peoples, wherever they occur, affect a sweet yodeling quality. In Azerbaijan and among the Kurds a strident yelping coloratura is highly prized among the professional minstrels or *ashugs*. (*See* also Folk Music.)

Various attempts have been made to classify the styles of folk singing, and Alan Lomax (*American Anthropologist*, vol. 61, no. 6, 1959) distinguishes among other families the "Eurasian," "Old European," and "Modern European" (to name only those close to the music of the Western world). We may take the Eurasian area to include Gaelic Ireland, parts of France, southern Spain and Italy, parts of Yugoslavia, southern Greece and Turkey, along with a number of Asian and north African countries. The area is characterized by solo song, unblended unison, and the use of accompanying instruments. The voice tone is high-pitched, tight-throated, often strident, with an emission suited to long-lined, decorated melodies.

The Old European tract may be said to include the Hebrides, Wales, Brittany, northern Spain, northern Italy, Switzerland, Germany, Scandinavia, Czechoslovakia, Poland, and the Ukraine. Here the song is mainly choral and collective, and accompaniment is unimportant. The voice is produced from a relaxed throat and is deeper-pitched than in the Eurasian area. The melodies are expressed in a relatively simple foursquare manner, with but sparse ornamentation.

The Modern European is described by Lomax as a hybrid style which grew up in the borderlands between Eurasian and Old European, and "most of the folk singing which western Europeans and Americans know" belongs to this style. Its area includes Lowland Scotland, parts of England, western and central France, central Spain, central Italy, and the greater part of "white" North America. It is characterized by solo songs sung in a hard, often nasal voice, with little ornament. As with the Old European—though not the Eurasian—style, the singer's interest and vocal emission are centred on text rather than tune, on sense rather than expression. With this style, timbre, dynamics, tempo, once established, remain constant throughout the song.

This classification may serve as a rough guide to the distribution of European and Western folk-singing styles, but to test its adequacy requires a more massive reservoir of knowledge than exists at present. It may be that the florid, tight-throated style of Eurasian singing—a style with common frontiers extending at least from Portugal, along both shores of the Mediterranean, and as far as India—derives from a current of musical practice that flowed out, both eastward and westward, probably from Mesopotamia in prehistoric times. The plain, relaxed style called here Old European—the frontiers of which may prove to extend from the Hebrides to the Tien Shan Mountains of Central Asia—is typical of another, even earlier, current, possibly from a Caucasian source.

It is repeatedly suggested that these various singing styles, along with those of the American Indians, Pygmoids, Bantu Africans, Australians, Melanesians, and Polynesians (to name the chief remaining families of distinguishable style), are related to institutional and emotional factors in the life of the exponents. These are considerations for the ethnographer and the psychologist. (A. L. Ll.)

From the Middle Ages to Bel Canto.—During the Middle Ages and Renaissance singers were theoretically divided into two still familiar categories: those who were technically proficient and, at the same time, were skilled musicians, and those who were merely the possessors of agile voices. A papal bull of 1324–25 likens the latter type of singer to "a drunkard, which indeed goeth home, but by which path he cannot tell." It is, in fact, possible to learn more about the abilities of the singers of this period from accounts of their performances recorded by outraged clerics and indignant musicians than from the more literary adulations of their admirers.

Two further contemporary sources of information on singing are the written music, where comparison of one manuscript with another will often show variations of vocal ornamentation that may point to a personal or a local style; and the popular music instruction books (*see* Musicology) that began to appear after 1500, many of which deal in some detail with singing. With these, however, as with their contemporary counterparts on instrumental playing, the modern reader is handicapped by the authors' assumption that the sounds they describe are familiar.

Indeed, the question of the quality of vocal (and instrumental) sound in early music—from, in fact, the Middle Ages to the advent of the phonograph—is a vexed one and is of crucial importance to any modern performance of the music. While musical styles have varied widely according to period, country, and individual, it is infinitely easier to reconstruct a past instrumental style than it is to form any idea of a past vocal style. The instrumentalist's technique is governed to a very large extent by the limitations and characteristics of his instrument. The enormous musical potentialities of the human voice, on the contrary, have remained constant for all periods; yet, while vocal styles must have varied as greatly as the instrumental style with which they coexisted, there is very little evidence to show what quality of

sound a medieval or Renaissance singer produced. It has been pointed out, however, that in many paintings of the 15th and 16th centuries singers are shown with tense facial muscles (in contrast to the relaxed expressions of the instrumentalists), which seems to point to a hard (to modern Western ears) vocal timbre and well-articulated attack. Furthermore, the vocal music of, for example, the period from the end of the 13th to the end of the 14th century requires remarkable vocal precision and agility, while the theoretical writings of that time, as well as those of later periods, suggest that an acute degree of exact intonation was demanded of both singers and instrumentalists.

While much medieval and Renaissance vocal music, in which the instrumental part often had an importance equal to that of the vocal line, required from the singer a strong sense of ensemble, the chordally accompanied song of the late 16th and early 17th centuries in Italy and France gave the solo singer a new freedom and a new dramatic role as interpreter of words and emotions. By the beginning of the 17th century a clearer view of vocal practice becomes possible, and singing teachers begin to publish books describing their methods. The old styles of vocal ornamentation, practically interchangeable with instrumental ornamentation, gave way to new, expressive, mannered, and purely vocal styles (*see* ORNAMENTATION), and the rise of opera put the virtuoso singer in a position of power over both composer and audience that he was to maintain for the next 200 years. (*See* also MUSIC, TEACHING OF; SONG.) (M. Mw.)

Bel Canto.—Singing, in its physical aspect, has a well-defined technique which depends on the use of the lungs, in the form of a bellows; on the larynx, which acts as a reed or vibrator; on the chest and head cavities, which have the function of an amplifier, as the tube in a wind instrument; and on the tongue, together with the palate, teeth, and lips, which articulate and impose consonants and vowels on the amplified sound. Though these four mechanisms function independently, they are nevertheless coordinated in the establishment of a vocal technique and are made to interact upon one another. From a musical viewpoint, the sounds produced by a singer are required to have tone quality; to be in tune; to be maintained in their tone quality; and to be capable of dynamic gradations. The technique of singing depends ultimately on the coordination of the various mechanisms designed to produce a propulsion of sound in a steady flow.

Modern styles of singing largely derive from the Italian *bel canto*, which has its origin in a style associated with the polyphonic music of the 16th century. Since this music was remarkable for its symbolism expressing the significance or the moods of the text, a great range of expression was required from the singers, who, in these polyphonic works, assumed something of the function of a vocal orchestra. The art of *bel canto* singing accordingly evolved to allow the singers the maximum power and variety of expression.

Bel canto singing was built primarily on the recognition that the intensity of vocal tone on a single note may be increased or diminished. The varying of this intensity was known as the *messa di voce*. There is, however, a difference between variation in intensity and variation in volume of vocal tone. The *bel canto* style depended on the technique of intensity; that is, tone was varied by increasing or decreasing the air pressure on the glottal lips and not by enlarging the oral chamber, which merely resulted in a larger tonal volume. The *bel canto* style was also based on the principle that the voice has two "tones," a diapason tone produced when the larynx is in a relatively low position, and a flute tone when the larynx assumes a higher position. Both singers and composers were aware of these distinctions, which, however, were largely obliterated when a broader style of singing was introduced by Wagner and later composers.

Among the different genres of the *bel canto* style was the *canto spianato*, using a great variety of colouring, as in the arias of Alessandro Scarlatti and his contemporaries; and the *canto fiorito*, or florid song, using the flute tone in agile arias and the diapason tone in dramatic arias. There was, furthermore, the *canto declamato*, or declamatory chant, of which the subdivisions were the *serioso* type, using the diapason tone, and the *buffo* type, usually sung in the flute tone. In the 18th-century *opera buffa*, accompanied recitative was sung in the full tone and *recitativo secco* in the lighter tone.

Physical aspects of the technique of *bel canto* singing demanded a stance in which the chest was raised and the stomach drawn in; the raising of the soft palate together with a corresponding lowering of the larynx; and the drawing back of the chin with the effect of opening the throat. Correct breathing was above all essential, and the Italians went so far as to declare that "he who knows how to breathe can sing." By a contraction of the upper abdominal muscles, control is achieved over the diaphragm, which thus enables the flow of air pressure from the lungs to be kept steady. This principle, which was the basis of singing in the 18th century, was later adopted by the Spanish tenor Manuel García, who declared that "the lungs are for tone emission, the glottis is for pitch, the oral cavity is for vowel and timbre, and the front of the mouth is for consonants." The function of the diaphragm is to regulate the pressure of air, while the larynx, as a nozzle in a water spray, determines the nature of the flow.

With the muscles in appropriate position and the reserve of air under proper control, accented notes in singing are given their full value not as startling percussive notes but in the manner of an accented note produced by a violinist who prepares his effect by the proper placing of his bow. An exercise known as *vibrazione* enabled the singer to control the voice at the larynx and, by attacking a note softly, to increase the volume by pressure of the larynx. These methods of tone production and control, used by García and later singers, originated from a practice known as *coup de glotte*.

Later Styles.—Later schools of singing paid much attention to the resonation of the voice in the "mask," that is, the cavities of the head, though this resonation did not affect the radiation power of the voice but only its volume. These singers, and also the still later *parlando* singers who effected a union of speech and singing, made a conscious use of resonation in this way and differed from the *bel canto* singers in that they exercised less control over physical mechanisms.

The development of the orchestra by Berlioz, Verdi, and Wagner encouraged singers to seek means of amplifying their voices by methods of resonation unknown in the *bel canto* style, and a new method was established of "singing on resonance." Jean de Reszke, who emphasized the function of the nose in resonation, was the main exponent of this school. Apart from the facial mask and the nose, other resonators were held to be the hard palate and the teeth. Followers of this school maintained that the voice should be "placed" in a particular area of resonation, according to the physique of the singer. This school also maintained that the underlying principle of the vocal art is to "sing as you speak."

Demands made on the voice by Wagner and later composers transformed the principles of the *bel canto* style, largely because the human voice would have been submerged by the vast orchestral resources drawn upon by these composers. Even so, the robust Wagnerian singers often had great difficulty in projecting their voices through the heavy orchestral texture. The technique of the *parlando* singer eventually enabled the *Sprechstimme* ("speaking voice") of Schoenberg and his followers to become established, while the use of the microphone in popular music led to an even closer approximation to the speaking voice.

In other developments of vocal music about the mid-20th century, the tendency, particularly when the singer was required to place emphasis upon an isolated word or a dramatic effect, was to associate the *parlando* and resonation styles with the remaining traditions of *bel canto* singing. *See* also VOICE.

SINGLE TAX, as the term originally developed, referred to a tax upon land values and was proposed as the sole source of government revenues, to replace all existing taxes.

The idea of a single tax on land is at least two centuries old, appearing, for example, in the writings of the 18th-century physiocrats and of the famous English economist David Ricardo. But the term itself and the modern single-tax movement originated with the publication of *Progress and Poverty*, the first systematic presentation of the plan, written by a San Francisco newspaper editor, Henry George (*q.v.*), in 1879. The proposal gained substan-

tial strength in ensuing decades, and then gradually declined in popular appeal. There were, however, in the second half of the 20th century still a number of very devoted disciples, the best known of whom was Harry Gunnison Brown, and publications in the field were sponsored by the Schalkenbach Foundation, established for this purpose.

The basic arguments for the single tax were twofold. On the one hand it was argued that land rent, unlike other income, is a product of the growth of the economy, not of individual effort, and thus society is justified in recovering it to support the costs of government. Since land rent is a surplus return, a tax on it cannot be shifted forward to consumers, and cannot reduce the supply of land available to the economy. Land rent is essentially an "unearned increment" and thus governments are justified in taxing it at a 100% annual rate. On the other hand, use of the tax would allow elimination of other forms of tax, and particularly taxes on buildings, which interfere with construction and economic development generally. Thus the tax would stimulate growth of the economy. The argument was also made that a single tax would be simple, uncomplicated, and economical to collect.

The critics of the proposal condemn the tax as contrary to usual standards of ability to pay, since there is no correlation between land ownership and total wealth and income. Portions of other incomes may be regarded as much "unearned" as land rent. If the tax were imposed today it would in large measure rest on the wrong persons, on those who had invested their capital in land rather than those who had benefited from the increase in land values. Furthermore, as a practical matter, separation of land values from those of buildings and other improvements would be extremely difficult.

While no attempt has ever been made to use the land tax as a single tax, and it is universally recognized that the levy could not meet all needs of government, several jurisdictions have applied their property taxes to land only instead of to land and buildings, or have taxed land more heavily than buildings. Examples include the states of Australia, the western provinces in Canada, the Commonwealth countries in East and Central Africa, and a few municipalities in the United States. A land tax was imposed for a short time in England before World War II, and "unearned increment" was taxed under the Labour government from 1945 to 1951. The single-tax supporters claim that the use of the plan in Australia has greatly stimulated building in the states using it, but the evidence is not conclusive.

SINHA, SATYENDRA PRASSANO (1ST BARON SINHA OF RAIPUR) (1864–1928), Indian lawyer and statesman, who had an extremely successful legal career, won high esteem in nationalist circles, and was appointed to high office under the British government, was born in the village of Raipur, Birbhum district, Bengal, in June 1864. He was educated at the Presidency College, Calcutta, and was called to the bar from Lincoln's Inn. He was the first Indian to be appointed advocate-general of Bengal (1907) and the first to be appointed to the governor-general's Executive Council, in which he served as law member during 1909–10. He was knighted in 1914, presided over the Indian National Congress Party's session at Bombay in 1915, and subsequently served in the Imperial War Cabinet. In 1919 he joined the Lloyd George ministry as undersecretary for India, being raised to the peerage as Baron Sinha of Raipur, and steered through the House of Lords the bill to enact the Montagu-Chelmsford proposals for the reform of the Indian constitution. In 1920 he was appointed governor of Bihar and Orissa, being again the first Indian to hold such office under the British, but resigned on grounds of ill health in the following year. He was appointed a member of the Judicial Committee of the Privy Council in 1926. He died on March 6, 1928, at Berhampur. (KE. A. B.)

SINHAILIEN (HSIN-HAI-LIEN), an important city and rail-terminal seaport on the Yellow sea in north Kiangsu province, China. It is an amalgamation of several settlements founded at different times, bearing many individual names between 1900 and 1949. Haichow (Hai-chou) was the name once applied to an old junk port at the coastal end of a canal system. Sinpu (Hsin-p'u) was the early inland eastern terminal of the Lunghai railway. Lao-yao and Lien-yun-kang appeared on some maps to name a new deepwater port built in the 1930s south of the unusable silted estuary of the Yun-yen Ho and Shu Ho. Tung-hai and Ta-p'u both were used as names for the central portion of the urban complex. Sinhailien, applied to the whole city, and Lien-yun-kang, applied to the port, were both in use in the second half of the 20th century. Pop. (1953) 207,600. (J. E. SR.)

SINHALESE LANGUAGE. Sinhalese is an Indo-European language of the Indo-Aryan family, spoken in the island of Ceylon by about 7,000,000 people (1965). It has developed along independent lines, because of the separation of Ceylon from the mainland of India and from the main Indo-Aryan language areas of north India by the Dravidian-speaking southern regions. In the 19th century the name "Sinhalese" was usually written "Cingalese"; the people themselves call it "Sinhala" (accent on first syllable).

The language has its own syllabic script, the letters or characters being of a generally rounded appearance. For literary purposes, there is a complete set of equivalents for all Sanskrit letters, but for representing the Sinhalese sounds, 12 vowel characters and 26 consonant characters are sufficient. Orthography, however, is not very fixed. Accent is not significant. The vocabulary is basically Indo-Aryan, with a considerable number of Dravidian (mostly Tamil) loanwords. There are also some Portuguese and Dutch loanwords bequeathed by the pre-British colonizers of Ceylon, and a large number of English loanwords. English loanwords, however, are still usually avoided in written Sinhalese. Words can be classified as noun, verb, or particle. Among nouns, five case-forms can be distinguished. In literary Sinhalese, finite verbs have the archaic personal inflections, but in the spoken language these are replaced by a single invariable form. Much use is made of a verbal absolutive (having done, having gone), and of a relative participle (cow eating grass; we living house; *i.e.*, the grass which the cow is eating; the house which we are living in).

The earliest surviving specimens of the language are brief inscriptions on rock, in Brahmi letters (*see* ALPHABET: *Other Alphabets*), of which the earliest date from *c.* 200 B.C. The language of these inscriptions does not appear to be greatly different from other Indian Prakrits (*i.e.*, chronologically Middle Indo-Aryan languages) at that time. About the 5th century A.D., however, considerable developments occurred, the course of which can be traced in barest outline through inscriptions; and by the period of the earliest surviving literary works, toward the end of the 10th century, both the language and the script are much closer to their present forms than to those of the early centuries. By *c.* 1250, the literary language had attained a form which has hardly varied since, though the 20th-century spoken language (still scarcely used for literary purposes) differs from it considerably.

There is a considerable literature dating from about A.D. 1000, nearly all Buddhist in inspiration and subject matter, and much of it in prose. The best known classical poets are Śrī Rāhula (15th century) and Alagiyavanna (*c.* 1600). Modern secular literature is entirely confined to the 20th century, and by 1950 had still not attained substantial proportions. The novels of W. A. Silva (d. 1957) have had a wide popularity.

SINING (HSI-NING), capital of Tsinghai Province, China, on the south bank of Sining River, a tributary of the Yellow River, and 110 mi. WNW of Lan-chou. Sining, which is situated on the northeast margin of the Tibetan highlands at an elevation of 7,500 ft., is the centre of an agricultural district east of Lake Koko Nor, producing spring wheat and barley. Wool, hides and salt are also marketed. Long linked only by highways with the rest of China, the city was in 1959 reached by a railroad from

Lan-chou. Sining is the gateway to the Tsaidam basin, where the Chinese have developed new petroleum fields and mining industries. Pop. (1953) 93,700. (T. Sd.)

SINKIANG (Hsin-Chiang), name of a former province of westernmost China, converted September 1955 into the Sinkiang Uighur Autonomous Region (Hsin-chiang Uighur Tzu-chih Ch'ü), a political division at the provincial level set aside for the Uighur ethnic minority. Area 635,829 sq.mi. (1,646,799 sq.km.) pop. (1957 est.) 5,640,000. The name Sinkiang means "new borderland" and is roughly coextensive with what was historically known as Chinese Turkistan.

Sinkiang is bordered on the northeast by the Mongolian People's Republic, on the southwest by Kashmir and a narrow strip of Afghanistan, and on the west and north by the Central Asian republics of the Soviet Union. Physiographically, Sinkiang consists of two mountain-ringed basins separated by the east-west-trending Tien Shan (*q.v.*). The Dzungarian basin, in the north, has an elevation of 600 to 1,500 ft., and receives summer rainfall that makes Dzungaria (*q.v.*) ideal as a grazing land. The Tarim (*q.v.*) basin, south of the Tien Shan, has an average elevation of 2,500 to 3,000 ft. It is much more arid than Dzungaria, and its centre is occupied by the sandy Takla Makan (*q.v.*) Desert. At the eastern end of the Tarim basin lies the salt lake and marshland of Lop Nor (*q.v.*).

Sinkiang is multinational. The Uighurs (*see* Uighur), a Muslim Turkic-speaking people, the most important ethnic group, numbered 3,640,125 (1953) and comprised 75% of the population. They settled primarily in irrigated agricultural oases along the northern foot of the Tien Shan, and around the edge of the Tarim basin. The second largest ethnic group is the Kazakh, also a Muslim Turkic people, related to the Kazakhs of the Soviet Union. They numbered 475,000 in Sinkiang in the 1953 census. Unlike the Uighurs, the Kazakhs are primarily nomadic herders and graze their livestock in the Dzungarian pasture lands where a separate political division (Ili Kazakh Autonomous Chou, with its capital at Kuldja) was set aside for them. The Kazakhs also have two autonomous *hsien* (counties), at Mu-lei-ho and Barkol (Chen-hsi), in eastern Sinkiang (*see* also Turkic Peoples).

There were about 300,000 Chinese in Sinkiang, residing mainly in cities and towns, where they worked as government officials, merchants, and professional people. Chinese Muslims (*Hui*), numbering 200,000 in 1953, were concentrated in the Urumchi area in the Ch'ang-chi Autonomous Chou and also in the Yen-ch'i Autonomous district, south of the Tien Shan. There were 120,000 Mongols in Sinkiang, occupied mainly as livestock herders. Mongol autonomous areas include the Boro Tala Autonomous Chou, on the south slopes of the Dzungarian Ala-Tau on the Soviet border; the Bayin Gol Autonomous Chou in the basin of the lake Baghrash Kol south of the Tien Shan; and the Kobuk-Sai-li Autonomous district, on the slopes of the Saur range on the Soviet border. The Kirgiz people (70,000 in 1953) constitute the Kizil Darya Autonomous Chou, north and west of Kashgar, adjoining the Kirgiz S.S.R. of the Soviet Union. About 20,000 Sibo people, a Tungusic group near Kuldja, and 15,000 Tadzhiks are also set up in an autonomous district. (*See* also Mongol; Tadzhik; Tungus.)

Sinkiang's economy is primarily agricultural. Its cultivated land was expanded after 1949 through addition of new irrigated areas, such as the Manas River project on the northern foot of the Tien Shan. Grain crops, mainly wheat, corn, kaoliang, and sorghum, and ginned cotton are important products of the Tarim basin oases. Sinkiang's livestock herds, estimated about 21,000,000 head in the late 1950s, included about one-quarter of China's sheep, which yielded more than 60% of the nation's wool. In the early 1960s industry was in an early stage of development, with handicrafts (cotton goods, paper, rugs, leather goods, and jade articles) accounting for two-thirds of the total value of manufacturing. The principal cities and their 1953 census populations are: the regional capital, Urumchi (140,700), Kashgar (91,000), Yarkand (80,000) (*qq.v.*), I-Ning (Kuldja) (108,200), and Aksu (90,000). The development of modern industry depends in part on the development of the region's mineral resources and the construction of modern transportation routes. Petroleum was produced on a small scale at Tu-shan-tzu, near Wu-su. A large petroleum centre at Karamai, 70 mi. N of Wu-su, was under development in the early 1960s. Mineral prospects also include tungsten, molybdenum, and other nonferrous metals, as well as coal and iron ore. A major railroad crossing Sinkiang from Kansu province to the junction of Aktogai on the Turksib Railroad in the Soviet Union was completed in the early 1960s.

South Sinkiang was controlled by China (200 B.C.–A.D. 220) during the Han dynasty. The Uighurs ruled for many centuries until the area was conquered by Genghis Khan and his successors and later by the Kalmyks. Sinkiang eventually came under Chinese control in the 17th century during the Ch'ing dynasty. It became a Chinese province in 1884. During the Nationalist period, warlords ruled Sinkiang, sometimes with Soviet support. Chinese Communists seized control in October 1949. (T. Sd.)

SINKING FUND: *see* Debt, Public.

SINO-JAPANESE WAR. For the first conflict known by this name, in which China and Japan fought (1894–95) over Korea, *see* Chinese-Japanese War. In this war, China was quickly defeated by Japan, which was then emerging as a world power. For the second Sino-Japanese War, which was part of World War II, *see* World War II: *The Chinese-Japanese War (1937–45)*. China suffered invasion on a vast scale but finally saw its enemy defeated.

SINOP (ancient Sinope), the chief town of Sinop *il* (province) on the north coast of Turkey, lies on a low isthmus joining the promontory of Karababa Tepesi (Boz Tepe) to the mainland, and 190 mi. (306 km.) NE of Ankara. Pop. (1960) 10,214. Though it possesses the only safe natural roadstead on the north coast of Asia Minor, the difficulties of communication with the interior and the rivalry of Inebolu on the west and Samsun on the east prevented Sinop from becoming a great commercial centre. The town is shut off from the plateau by forest-clad mountains. On the isthmus, toward the mainland, stands a huge but mostly ruined castle, originally Byzantine and afterward strengthened by the Seljuk sultans. Of early Roman or Greek antiquities there are only the columns, architraves, and inscribed stones built into the old walls; but the ancient local coinage furnishes a very beautiful and interesting series of types.

Sinope, whose origin was assigned by its ancient inhabitants to Autolycus, a companion of Hercules, was founded sometime in the 7th century B.C. by the Ionians of Miletus, and ultimately became the most flourishing Greek settlement on the Black Sea. This was so because it was not only a port but the terminus of a great caravan route from the Euphrates to the Black Sea, over which were brought the products of central Asia and Cappadocia (whence came the famous "Sinopic" red earth, probably red ochre). In the 5th century B.C. it received a colony of Athenians, and by the 4th it had extended its authority over a considerable tract of country. Its fleet was dominant in the Black Sea, except toward the west, where it shared the field with Byzantium. When in 220 B.C. Sinope was attacked by the king of Pontus, the Rhodians enabled it to maintain its independence. In 183 B.C. the city, taken by surprise and captured by Pharnaces I, became the capital of the Pontic monarchy (*see* Pontus). Under Mithradates VI the Great, who was born in Sinope (as was Diogenes), it had just been raised to the highest degree of prosperity, with fine buildings, naval arsenals, and well-built harbours, when it was captured by Lucullus and nearly destroyed by fire (70 B.C.). Under Julius Caesar the city became a Roman colony, but was already declining with the diversion of traffic to Ephesus, the port for the Roman Empire, and in part to Amisus (Samsun).

In the Middle Ages it became subject to the Greek Empire of Trebizond (Trabzon), and passed into the hands of the Seljuk Turks; and in 1461 was incorporated in the Ottoman Empire. In November 1853 the Russian vice-admiral P. S. Nakhimov destroyed there a division of the Turkish fleet and reduced a good part of the town to ashes; this incident helped to sway British opinion in favour of entering the Crimean War.

Sinop Il had a population in 1960 of 249,730. It is mountainous and drained by the Gok Irmak. Olives, flax, and tobacco are the chief crops. (N. Tu.; S. Er.; E. Tu.)

SINO-TIBETAN LANGUAGES: *see* SOUTHEAST ASIAN LANGUAGES.

SINS, SEVEN DEADLY, a classification that goes back to the early history of Christian monasticism. A sin was classified as deadly not merely because it was a serious offense morally but because "it gives rise to others, especially in the manner of a final cause" or motivation (Thomas Aquinas). The traditional catalogue of the seven deadly sins is: (1) vainglory or pride; (2) covetousness; (3) lust, understood as inordinate or illicit sexual desire; (4) envy; (5) gluttony, which usually included drunkenness; (6) anger; and (7) sloth, sometimes called acedia or accidia. The classical discussion is in Thomas Aquinas, *Summa theologiae*, i-ii, Q. 84, art. 4. (J. J. PN.)

SINTER, in petrology, certain mineral deposits, more or less porous or vesicular (cinderlike) in texture. At least two kinds of sinter are recognized: one siliceous, the other calcareous. Siliceous sinter is a deposit of opaline or amorphous silica from hot springs and geysers, occurring as an incrustation around the springs, and sometimes forming conical mounds or terraces. The deposition of siliceous sinter is largely due to the action of algae and other forms of vegetation in the thermal waters. Siliceous sinter has also been called geyserite and fiorite.

Calcareous sinter, sometimes called tufa, calcareous tufa, or calc-tufa, is a deposit of calcium carbonate, exemplified by travertine, which formed the principal building stone of Rome, and was named from the Italian *travertino*, a corruption of *tiburtino*, the stone of Tibur, now Tivoli (*see* STONE). So-called petrifying springs, not uncommon in limestone districts, yield calcareous waters which deposit a sintery incrustation on objects exposed to their action.

The cavities in calcareous sinter are partly due to the decay of mosses and other vegetable structures that have assisted in its precipitation. Even in thermal waters, like the hot springs of Carlsbad, Bohemia, which deposit *Sprudelstein*, the origin of the deposits is mainly due to organic agencies, as shown as far back as 1862 by the German botanist Ferdinand Julius Cohn. While calcareous deposits in the open air form sinterlike travertine, those in caves constitute stalactites and stalagmites. *See* also CALCITE; STALACTITES AND STALAGMITES.

SINT-NIKLAAS (SAINT NICOLAS), a town of Belgium in East Flanders province, lies 13½ mi. (22 km.) WSW of Antwerp. Pop. (1961) 47,819. The town is a rail junction and the centre of the Waasland market-gardening district, its market place of 7½ ac. (3 ha.) being the largest in Belgium. Notable buildings are the new town hall (1876), the old town hall (1663) and other 17th-century buildings, the Church of St. Nicholas (15th–16th century; restored 1900), and Walburg Château (16th century) in the public park. The museum contains a Mercator collection. The town received its charter in 1513 and has textile industries. (J. DR.)

SINTRA (CINTRA), a town of Lisboa district, west central Portugal, lies 17 mi. (28 km.) W.N.W. of Lisbon by rail or road. Pop. (1960) 20,321. It is picturesquely situated on the northern slope of the Serra de Sintra, a rugged mountain mass largely overgrown with pine, mimosa, cedar, eucalyptus, cork and other trees, above which rise bare and jagged gray rocks (Cruz Alta, 1,732 ft.). The beauty of Sintra is celebrated by Lord Byron in *Childe Harold* and by Luís Vaz de Camões in *Os Lusíadas*. On one of the peaks is the Palacio da Pena, a fantastic 19th-century building, partly an adaptation of a 16th-century monastery and partly an imitation of a medieval fortress. On another peak is the Castelo dos Mouros, an extensive Moorish fortification. In the town itself is a 12th–15th-century royal palace, partly Moorish, partly debased Gothic, and remarkable for the decoration of its rooms and its two immense conical chimneys. On the road to the village of Colares are the palace and park of Montserrate. The park, with its tropical luxuriance of vegetation and its variety of lake, forest and mountain scenery, is one of the finest examples of landscape gardening in the Iberian peninsula.

Sintra has given its name to two conventions, one in 1509 between Portugal and Castile settling differences concerning voyages of exploration, and one in 1808 by which the British and Portu-

BURTON HOLMES FROM EWING GALLOWAY

guese allowed the beaten French army to return home during the Peninsular War.

SINŬIJU (Japanese, SHINGISHU), a city and capital of North Pyongan Province, North Korea, was developed by the Japanese during their occupation (1910–45) at a site 7 mi. W of the old city of Uiju where a railroad bridge was built across the Yalu River connecting with the Manchurian city of Antung. Sinŭiju (or New Uiju) is an industrial and commercial city and wood rafted down the Yalu forms the base of a large forest products industry. Trade with Manchuria and China is funneled through the city to Korea. Pop. (1958 est.) 200,000. (S. McC.)

SINUS, in anatomy, is a space filled with blood (*e.g.*, in the dura mater covering the brain) or air (*e.g.*, in the cranial bones). The word is also used by surgeons to signify a discharging tract that will not heal and has in many cases a foreign body or dead bone at the bottom. Popularly, the term sinus is used most often to designate one of the air cavities (paranasal sinuses) connected with the nose. The largest of these cavities (maxillary sinus), is in the cheekbone. The next in size is in the forehead (frontal sinus). Smaller cavities open into the back (sphenoidal sinus) and sides (ethmoidal sinus) of the nose. The paranasal sinuses are lined with ciliated mucous membrane continuous with that of the nose.

Sinusitis is the medical term for disease of the paranasal sinuses, popularly called sinus trouble. Sinusitis may be either acute or chronic.

Acute sinusitis may occur as an aftermath of a cold, due to secondary bacterial infection, or it may be precipitated by faulty breathing habits in swimming or by sudden changes in barometric pressure in flying or diving. Allergy and conditions resulting in lowered general resistance may predispose to attacks. Infections of the upper molar and bicuspid teeth may cause acute maxillary sinusitis.

Symptoms are pain and headache, tenderness over the affected area, nasal obstruction and discharge and malaise. Conservative

treatment, bed rest, fluids, heat externally, sedation for pain, and vasoconstrictor sprays to relieve obstruction generally are effective. Persistence of symptoms may indicate the use of suction to promote drainage, and antibiotic therapy, based upon culture and sensitivity studies. X-ray examination may suggest irrigation of the maxillary or external drainage of the frontal sinus.

Chronic sinusitis may follow repeated or neglected attacks of acute sinusitis, particularly if there is impaired nasal breathing and drainage due to intranasal obstruction. These may be aggravated by poor environmental conditions, dust or excessively dry air of heated dwellings. Dental infection in the upper molar and bicuspid area may cause chronic disease in the maxillary sinus.

Symptoms are tendency to colds, purulent nasal discharge, obstructed breathing, loss of smell and sometimes headaches. Pain is rare except during acute phases. Foul-smelling discharge may indicate dental origin. While there may be increased postnasal discharge, its significance often is overstressed, as the normal drainage from the nose is posteriorly to the pharynx. Frequently symptoms attributed to sinusitis may be manifestations of general conditions (particularly allergy or disturbance of the endocrine system) or result of faulty nutritional or living conditions or of habitual use of nasal sprays or drugs. Stress and tension may be contributing factors.

Successful treatment depends upon a thorough systematic evaluation of the patient, including X-ray and other diagnostic studies, to determine not only the status of the sinuses but also the significance of any underlying conditions. Surgery may be indicated to restore ventilation and drainage, to eliminate irreversibly diseased tissues, and to avoid complications. (S. HA.; F. T. HI.; X.)

SION (SITTEN), capital of the canton of Valais, Switzerland, is at an altitude of 1,700 ft. (518 m.) in the Rhone Valley, 60 mi. (97 km.) SE of Lausanne. Pop. (1960) 16,051. It is built around two prominent hillocks: the northern has the remains of the 13th-century Tourbillon Castle and the southern, those of the castle of Valère (Valeria), now containing a historical museum and a mainly 13th-century church. Other notable buildings are the Gothic Cathedral of Notre-Dame, St. Theodule's Church, and the 17th-century town hall. The town is linked by road with the summer and winter resorts of the canton, and is on rail and road routes from Lausanne to Milan via the Simplon Pass (*q.v.*) and Tunnel. Sion (ancient Sedunum) dates from Roman times and became an episcopal see in the 6th century. From 999 the bishops of Sion held the temporal and spiritual power in Valais which they retained, at least in part, until 1798 (*see* VALAIS: *History*).

SIOUAN INDIANS, North American linguistic family that takes its name from that of the largest tribe, the Sioux or Dakota (*q.v.*). Next to Algonkians, they were perhaps the most populous stock north of Mexico. They held three territories, the largest mainly west of the Mississippi River, another east of the Appalachian Mountains in Virginia and the Carolinas; the smallest, in two fragments, in Mississippi. The last two divisions are nearly extinct. The culture was not uniform, but accorded with the region in which each tribe lived. Physical types probably varied similarly. In the Great Plains, the Siouans were the preponderant linguistic stock (*see* PLAINS INDIANS). The principal Siouan tribes were (those asterisked being separately treated): (1) in the west, *Dakota and *Assiniboin, the former really seven tribes; *Mandan, *Hidatsa, and *Crow; *Winnebago; tribes speaking the Chiwere dialect, namely the Iowa, Oto Missouri; tribes speaking Dhegiha, viz., *Omaha, Ponca, Kansa, *Osage, Quapaw or Arkansa; (2) in the south, Ofo and *Biloxi; (3) in the east, Monacan, Manahoac, Tutelo, Saponi, Occaneechi, Woccon, Catawba, Santee, Cheraw or Saraw, and probably Wateree, Congaree, Pedee, and others. In the 1960s there were about 60,000 Siouan Indians; their highest level of population was probably at least 80,000. *See* also DORSEY, JAMES OWEN; and references under "Siouan Indians" in the Index.

See W. L. Chafe, "Another Look at Siouan and Iroquoian," *American Anthropologist*, vol. 66 (Aug. 1964). (A. L. K.; X.)

SIOUX CITY, a city of northwestern Iowa, U.S., lies on the bluffs of the Missouri at the mouths of the Big Sioux and Floyd rivers, where the states of Iowa, South Dakota and Nebraska meet; a port of entry and the seat of Woodbury county.

In 1804 Captains Meriwether Lewis and William Clark visited the site of Sioux City and there buried Sgt. Charles Floyd, the only man lost on their famous journey (*see* LEWIS AND CLARK EXPEDITION). Theophile Bruguier, a French-Canadian fur trader, settled there in 1849 and married the daughter of War Eagle, a powerful chief of the Yankton Sioux. In 1854 John K. Cook platted Sioux City while surveying the region for the U.S. government. It prospered originally as a supply centre for the northern plains and as a land-office town. The first steamboat from St. Louis reached Sioux City in 1856 and in 1857 the city, with a population of 400, was incorporated. The first railroad arrived in 1868 and the first meat-packing plant was opened a few years later. During the boom of the 1880s, when settlers occupied northwestern Iowa and the Dakotas, the packing industry expanded and the population jumped from 7,366 to 37,806. Although retarded by depression in the 1890s, during which its population dropped, Sioux City grew rapidly between 1900 and 1920, when its population topped 70,000. Pop. (1960) 89,159; standard metropolitan statistical area (Woodbury county, Iowa, and Dakota county, Neb.) 120,017. (For comparative population figures *see* table in IOWA: *Population*.)

Early settlers in Woodbury county came mainly from the Ohio valley, New York, Pennsylvania and older Iowa. French Canadians, Germans and Scandinavians also settled there and a Russian group was present by 1900. A community of Negro packing-house workers developed after 1910.

Commerce is marked by heavy wholesale trade and grain exchange activity. Industries include meat packing, food processing, and feed and clothing production, as well as other diversified manufactures.

Morningside college, a Methodist liberal arts institution which maintains a conservatory of music, was founded in Sioux City as the University of the Northwest in 1889. In 1930 the Sisters of St. Francis established Briar Cliff college (Roman Catholic) for women. Sioux City has a symphony orchestra and an extensive park system in which are preserved memorials of Indian days including War Eagle's grave and the Council Oak of the Sioux. Sioux City adopted a commission form of government in 1910 and in 1953 switched to the council-manager plan. (A. G. Bo.)

SIOUX FALLS, the seat of Minnehaha County, in southeastern South Dakota, U.S., a few miles from the Minnesota border and about 75 mi. N of Sioux City, Ia., on the rolling hills and in the wooded valley bordering the Big Sioux River. Pop. (1960) 65,466; standard metropolitan statistical area (Minnehaha County) 86,575. (For comparative population figures *see* table in SOUTH DAKOTA: *Population*.) The population of the city is much like that of the Dakota farm area, heavily Scandinavian and German.

Except for an early fur-trading establishment that later became Fort Pierre, Sioux Falls is the oldest community in South Dakota. It was founded in 1857 by Iowa and Minnesota land speculators who were disappointed when in 1861 Yankton, rather than Sioux Falls, was named capital of the new Territory of Dakota. The settlement was deserted during the uprising of the Minnesota Sioux which started the following year. Permanent settlement dates from 1870; it was incorporated as a village in 1877 and as a city in 1883. With the influx of settlers during the Dakota boom of the 1880s, followed by the decline in importance of steamboat transportation which had given Yankton its earlier prominence, Sioux Falls developed into the principal community in the state. The falls of the river, from which the city takes its name, were harnessed for water power in 1873 and the shipment of "Sioux Falls granite," a hard quartzite once used for paving blocks and as a building stone, began with the arrival of the first railroad in 1878. Because of the laxity of the South Dakota divorce laws prior to 1908 Sioux Falls was for a time nationally famous as a "divorce mill."

Located in an area of diversified farming where corn is the principal crop and livestock feeding the main source of income, Sioux Falls came into its own as a result of the wide use of trucks and the increasing dependence of farmers upon specialized farm

machinery, fertilizers, and mixed feeds. A distributing centre for the neighbouring farm area of Iowa, Minnesota, and South Dakota, it has over 200 wholesale firms. Its main industries are food processing, particularly meat packing, and wood and metal fabrication. Farm prosperity of the World War II period, which lasted several years after the war, also helped to build Sioux Falls as a shopping, entertainment, and commercial centre.

Educational facilities include Augustana, a Lutheran college founded in 1860, and Sioux Falls College, a Baptist institution established in 1883. The city has several parks and two golf courses. It has superior medical facilities, including a veterans hospital and a crippled children's hospital. The state penitentiary and a school for the deaf are also located there. (E. W. St.)

SIOUX INDIANS: *see* Dakota; Siouan Indians.

SIPHNOS (modern Greek Sifnos), an island of the Cyclades, Greece, 30 mi. (48 km.) SW of Syros. Area 32 sq.mi. (82 sq.km.); pop. (1961) 2,258. Along the west slope of a limestone ridge, whose principal summits, Ayios Ilias (2,129 ft. [649 m.]) and Ayios Simeon (1,624 ft. [495 m.]), are crowned by old Byzantine churches, lie a series of villages. Apollonia, the modern capital, has the name of an ancient town; Kastro, which has medieval fortifications, represents the ancient city of Siphnos; excavations by the British have yielded finds from the 8th century B.C. to Roman times. In ancient times Siphnos was colonized by Ionians from Athens. It refused tribute to Xerxes, and sent one ship to fight on the Greek side at Salamis (480 B.C.). The great wealth of Siphnos came from its gold and silver mines, from the proceeds of which it built a treasury at Delphi about 525 B.C. (*see* Greek Art); but by the 1st century A.D. these were flooded and the island was poor. Byzantine churches and convents are scattered about the island. The School of the Holy Tomb was founded by Greek refugees from the iconoclastic persecutions at Byzantium and became a centre of Greek culture until the 19th century. After the capture of Constantinople in 1204 Siphnos became part of the Venetian duchy of Naxos from 1207, but was recovered by the Byzantines in the 1270s. Regained by the Venetians, it was ruled by the Da Corogna family (1307–1456) and after 1456 by the Gozzadini, who were not expelled by the Turks until 1617. Olive oil is a principal product. (J. Bo.)

SIPHON (Syphon), an instrument, usually in the form of a tube bent to form two legs of unequal length, for conveying liquid over the edge of a vessel and delivering it at a lower level (Lat. *sipho;* Gr. *siphon,* "a tube"). A siphon also affords a ready method of transferring liquids over a hump or elevation. The action depends upon the difference of the pressure on the liquid at the extremities of the tube, the flow being toward the lower level and ceasing when the levels coincide. Siphons are made of glass, rubber, copper, or lead, according to the liquid which is to be transferred. The simple siphon is used by filling it with the liquid to be decanted and plunging the shorter leg into the liquid to be drawn.

Innumerable forms of siphons have been devised, adapted for all purposes, and provided with arrangements for filling the tube or for keeping it full and starting it into action automatically when required. Pipes conveying the water of an aqueduct across a valley and following the contour of the sides are siphons when they depend on the principle of the above instrument. Such a large siphon must be fitted with a valve for allowing the escape of entrapped air at the top of the hump or upper elevation of the siphon pipeline. In the siphon used as a container for carbonated (aerated) waters a tube passes through the neck of the vessel, one end terminating in a curved spout, the other reaching to the bottom of the vessel. When a spring valve on the tube is opened, the water is driven out by the pressure of the gas it contains. The "Regency portable fountain," patented in 1825 by Charles Plinth, was the prototype of the modern siphon; it differed in having a stopcock in place of a spring valve. The *siphon champenois* of Deleuze and Dutillet (1829) was a hollow corkscrew, with a valve, which was passed through the cork into a bottle of effervescent liquid. The *vase siphoïde* of Antoine Perpigna, patented in 1837, was essentially the modern siphon, its head being fitted with a spring valve.

SIPHONAPTERA: *see* Flea.

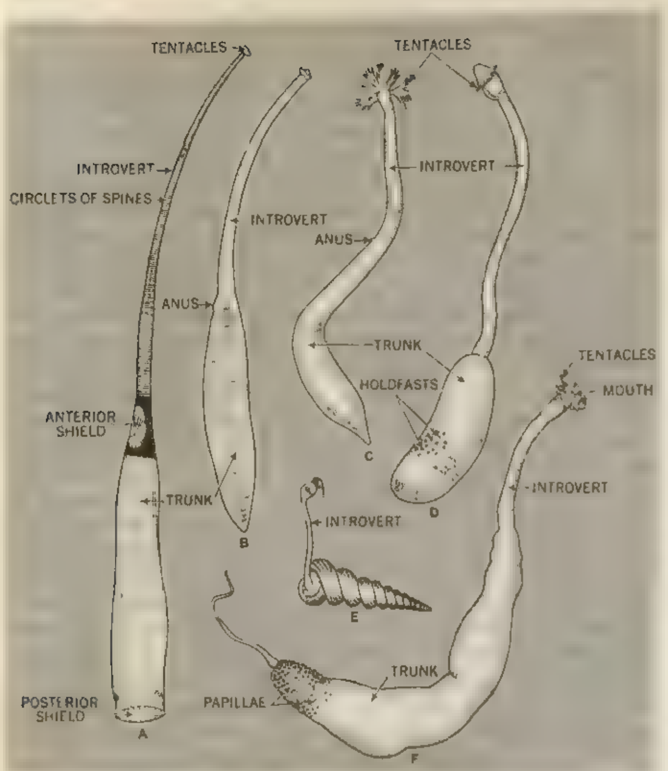
SIPPAR, an ancient city of Babylonia on the east bank of the Euphrates, identified with Abu Habbah (Tell Abu Habbah), about 20 mi. (32 km.) SW of Baghdad, Iraq. In 1881–82 H. Rassam began tracing a rectangular temenos wall which measured 1,050 × 787 ft. (320 × 240 m.); it enclosed a ziggurat with temples dedicated to the sun-god Shamash and to the goddess Anunitum. The city was subject to the 1st dynasty of Babylon. Later kings of this dynasty fostered the cult of Shamash; Hammurabi among others repaired the city walls, dug a moat, dredged the Euphrates, and built a protective quay. After the 1st dynasty of Babylon little is known about Sippar till 1174 B.C. when it was sacked and looted by the Elamite king Kutir-Nahhunte. It must have recovered, for it was captured by the Assyrian king Tiglath-pileser I, *c.* 1100 B.C. Sippar, however, survived these shocks and under the 8th dynasty of Babylon King Nabu-apal-iddina, *c.* 880 B.C., rebuilt the great temple of Shamash, which had previously been wrecked by the nomadic Sutu of the desert. This king recorded that while digging in the ruins he found the ancient image of the god, and he depicted himself on a stone memorial tablet as a suppliant before Shamash, who is enthroned beneath a canopy; in front of him the sun-disk, suspended from heaven by a rope, rests on an altar. This tablet, now in the British Museum, was found by King Nabopolassar (626–605 B.C.) when he restored the temple. Thousands of cuneiform tablets, mostly commercial, and contemporary with Nabonidus, the last king of Babylon, have come from this site. After the Battle of Opis (539 B.C.), when Nabonidus' army was defeated by the Persian king Cyrus, Sippar opened its gates and offered no resistance to the conqueror.

Bibliography.—H. Rassam, *Asshur and the Land of Nimrod* (1897); L. W. King, *A History of Babylon* (1919); W. Andrae and J. Jordan, "Abu-Habbah-Sippar" in *Iraq*, vol. i (1934); A. Parrot, *Archéologie mésopotamienne* (1946); T. Jacobsen, "The Waters of Ur" in *Iraq*, vol. xxii (1960). (M. E. L. M.)

SIPUNCULIDA, a phylum of bottom-dwelling marine worms that inhabit burrows, tubes, or borrowed shells; they are adapted to this mode of life by a forward displacement of the anus, on the dorsal surface near the base of the protrusible proboscis, or introvert. The body is thus elongated in a ventral direction almost at right angles to the anteroposterior axis, as it is in Bryozoa and Phoronida (*qq.v.*). This curious arrangement led E. R. Lankester to coin the now obsolete name Podaxonia for these three otherwise unrelated groups. The Sipunculida are distinguished from the Annelida (*q.v.*) not so much by the position of the anus—in some annelids the anus may be displaced forward dorsally—as by the total lack of segmentation. The former phylum Gephyrea, which included organisms now referred to the Sipunculida, Echiurida, and Priapulida, cannot be sustained in view of the lack of relationships between its members.

Natural History.—Although sipunculids are bottom dwellers, it is not necessary for them to inhabit U-shaped tubes with entrance and exit holes, as in the case of echiurids and many tube-dwelling annelids, since the anus is shifted forward toward the mouth. Some species burrow to considerable depths; others construct tubes by cementing sand grains together; while yet others live in abandoned tubes of annelids or shells of mollusks. Some species of *Aspidosiphon* form a symbiotic relationship with a coral that grows on the outside of the snail shell originally inhabited by the worm: as the coral grows, the worm enlarges its tube, which becomes encased in the calcareous base of the coral. In this and related genera, horny or calcareous preanal plates are used to close the mouth of the burrow.

The group is found predominantly in shallow water along shores, but representatives have been taken from great depths of the ocean: the "Galathea" expedition (1950–52) recorded sipunculids from the Kermadec Deep, off New Zealand, at 26,935 ft. (8,210 m.). Some species are almost cosmopolitan, such as *Sipunculus nudus;* others may be circumarctic or circumtropical. Each geographical area tends to have its characteristic assemblage of species. Antarctic species are frequently identical with, or closely related to, forms that occur in the far north; *e.g. Golfingia* species and *Phascolion strombi.* However, the great majority of species are found in warmer waters.



FROM L. H. HYMAN, "THE INVERTEBRATES: SMALLER COELOMATE GROUPS" (VOL. V), MCGRAW-HILL BOOK CO., INC.

FIG. 1.—TYPES OF SIPUNCULOIDS: (A) ASPIDOSIPHON SPECIOSUS; (B) GOLFINGIA MINUTA; (C) DENDROSTOMUM; (D) PHASCOLION STROMBI; (E) P. STROMBI IN A SNAIL SHELL; (F) GOLFINGIA FLAGRIFERA

Some species, like those found in the Baltic Sea, are tolerant of moderately low salinity levels. A Sumatran species, *Phascolosoma lurco,* is terrestrial, living in mangrove soil, much like an earthworm. A former supposedly planktonic genus, *Pelagosphaera,* is now known to be a larval stage: its metamorphosis has been observed and recorded.

External Characters.—The body of a sipunculid is divided into two regions, a trunk consisting chiefly of the elongated belly of the worm and a retractile introvert that bears the mouth at its anterior end. The mouth is partly or completely surrounded by tentacles or tentacle-bearing folds. The introvert was called a proboscis by earlier authors but the term, although descriptive, is misleading. Retractor muscles, typically four but sometimes only two or one, originate from the body wall of the trunk region at the base of the tentacles. Contraction of these muscles serves to withdraw the introvert into the body like the finger of a glove. Evagination depends upon hydraulic pressure developed in the coelomic fluid by contraction of the body musculature. In *Xenosiphon* eversion is effectively aided by the action of a pair of protractor muscles.

The number and arrangement of the tentacles varies widely. The mouth of *Sipunculus* is encircled by a lobed tentacular fold, frequently indented dorsally so that it assumes the shape of a horseshoe. In many genera the tentacles arise individually and in some instances they do not form a complete circle, as in species of *Aspidosiphon.* Sometimes, as in many species of *Golfingia,* the tentacles are arranged in tiers or concentric rings. Four to eight branching featherlike tentacles characterize species of the genus *Dendrostomum.* In very small species, such as those of the genus *Onchnesoma,* the tentacles may be greatly reduced or completely absent.

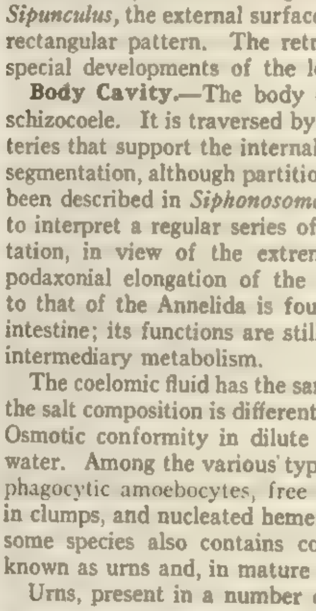
The introvert may be smooth, but, more frequently, it is armed with cuticular spines and hooks whose form and arrangement assume importance for the identification of the species. The anus, usually at the base of the introvert, is shifted far forward, near to the mouth in *Onchnesoma.*

The shape of the trunk varies greatly; it may be short and saclike, or long and vermiform. In *Phascolion strombi,* a common North Atlantic species that inhabits self-cemented tubes of sand grains or empty shells of mollusks, the shape of the body depends on that of the container in which the animal lives. Individuals that inhabit gastropod shells acquire a spiral twist that is almost completely lacking in sipunculids that dwell in straight tubes. The apex of the trunk is usually rounded, but in some deep-sea species of *Golfingia* it is drawn out to form a slender tail. In *Aspidosiphon* there is an apical caplike calcified structure resembling an acorn.

Body Wall.—A simple epithelium secretes a protective cuticle, thicker on the trunk than on the introvert. When horny or calcareous places are present, they are special secretions of the epidermis. Glandular and sensory papillae, frequently accompanied by hooks and holdfast organs, are found on the trunk and on the introvert, but some species are almost completely smooth. Beneath the epidermis is a connective tissue layer, more fully developed in some of the larger species. Coelomic diverticula may penetrate into the body wall; in *Sipunculus* they form longitudinal connecting canals between the muscle bands. The muscular coat consists of circular, oblique, and longitudinal layers; the oblique layer is sometimes lacking. The circular coat is usually divided into bundles; when the longitudinal coat is also so divided, as in *Sipunculus,* the external surface of the body reflects the underlying rectangular pattern. The retractor muscles of the introvert are special developments of the longitudinal coat.

Body Cavity.—The body cavity, or coelom, is technically a schizocoele. It is traversed by muscular strands and small mesenteries that support the internal organs but shows no trace of true segmentation, although partitions resembling segmental septa have been described in *Siphonosoma cumanense.* It would be difficult to interpret a regular series of septa of this sort as true segmentation, in view of the extreme displacement of the anus and podaxonial elongation of the body. Chloragogue tissue similar to that of the Annelida is found on the coelomic surface of the intestine; its functions are still problematical but are involved in intermediary metabolism.

The coelomic fluid has the same osmotic pressure as seawater but the salt composition is different; only traces of protein are present. Osmotic conformity in dilute media results from the uptake of water. Among the various types of corpuscles may be mentioned phagocytic amoebocytes, free chloragogue cells often aggregated in clumps, and nucleated hemerythrocytes. The coelomic fluid of some species also contains complex ciliated vaselike structures known as urns and, in mature individuals, developing sex cells.



FROM T. JEFFERY PARKER AND WILLIAM A. HASWELL, "A TEXT-BOOK OF ZOOLOGY", MACMILLAN & CO., LTD.

FIG. 2.—DISSECTION OF SIPUNCULUS NUDUS

Urns, present in a number of genera, are crowned by a single ciliated cell and are attached to the coelomic epithelium, the location depending on the species. In some forms the urns become detached and float in the coelomic fluid. The free urns of *Sipunculus* are budded off from the surface of the tentacular blind sac (*see* below), those of *Phascolosoma* are derived from the gut wall. Each urn is a closed vesicle covered by flat peritoneal cells with adherent chlorogogue tissue and containing fluid with connective tissue strands in its interior. A single ciliated cell sits like a cap on the vesicle, its circlet of cilia forming the brim, as it were, of the hat. The urns are believed, by their movement, to aid in the circulation of the coelomic fluid; the ciliary beat is such that foreign particles are collected in the central crown of the cap and eventually eliminated.

Tentacular System.—Canals lined by an endothelium similar

to that lining the coelom form a tentacular system, sometimes miscalled the vascular system. A circular lophophoral vessel, forming a ring surrounding the mouth, is closely associated above with the brain; canals extend forward from it into the tentacles and one or two backwardly projecting blind tubular sacs lie against the wall of the esophagus. These pouches have been miscalled hearts or, more often, Polian vesicles, on account of their resemblance to structures of this name in the Echinodermata (*q.v.*). Circulation of fluid, attributed to ciliary action, has repeatedly been observed within the tentacular canals: a peripheral flow in the lateral channels and a return flow in the median channel of each tentacle. In *Dendrostomum signifer* the blind sac is a pulsating organ that pumps fluid in and out of the lophophoral canals by frequent reversals of its beat. The circulation of the fluid, with its contained erythrocytes, can thus subserve a respiratory function. On the other hand, in forms like *Sipunculus*, in which the tentacles are short, the primary function may be hydrostatic. When the introvert is everted, the pressure set up in the body cavity compresses the blind sacs and fluid is thus forced into the tentacles, causing them to become extended. L. H. Hyman therefore proposed the name "compensation sacs" for the so-called Polian vesicles.

Digestive System.—The mouth lacks jaws. A ciliated esophagus, lying in the introvert, is followed by the long, coiled midgut. A true stomach is absent, although, in some species, a specialized glandular region at the junction of esophagus and midgut is usually called a stomach. The midgut passes backward to the apex of the body and then forward again to the anus. The descending and ascending limbs of the loop are usually twisted together in a spiral. This spiral is frequently supported by a spindle muscle that originates near the anus, traverses the central axis of the spindle, and is inserted apically. The midgut opens into a short hindgut that often receives a blind sac; terminally, there may be rectal glands of unknown function. A ciliated groove, externally visible as a reddish line, runs along the whole length of the alimentary canal in *Sipunculus* or is restricted, as in *Golfingia*, to the ascending limb of the intestine.

Sipunculids feed on organic matter contained in mud or sand taken up by the tentacles and swept into the mouth by ciliary action. Since the midgut is generally laden with such material, it has been suggested that these worms play an important role in the comminution of the sea bottom, similar to that played by earthworms on land. It has been suggested that the descending limb of the intestine is the main seat of digestion.

Vascular System.—A true vascular system is apparently lacking, although it may be represented, at least in *Sipunculus*, by a closed system of lacunae in the walls of the intestine.

Respiration.—Respiratory exchanges take place through the skin, and in forms like *Sipunculus*, which have subepidermal coelomic canals, this function probably is greatly facilitated. In forms like *Dendrostomum* the gill-like plumose tentacles may be the chief organ of respiration.

Hemerythrin, the respiratory pigment of the erythrocytes, is deep pink when oxidized and almost colourless when reduced. The dissociation curve of hemerythrin is such that the pigment gives up oxygen to the tissues only when there is an oxygen deficiency. Littoral species may be confined to their burrows during exposure at low tides and, as in tube-dwelling annelids and Echiurida (*q.v.*), the respiratory pigment may subserve a low tension transport function.

Excretory Organs.—A pair of excretory tubules (metanephridia) of relatively simple structure opens on the ventral surface of the body in front of the level of the anus. In *Phascolion* and *Onchnesoma* the development of one member of the pair, usually the left, is suppressed. The tube may be straight or U-shaped, and the limbs of the U may be more or less completely fused. Excretion takes place, at least in part, through the mediation of special cells lining the tube and also, apparently, by the migration of cell bodies called excretophores from the coelomic fluid into the lumen. The ciliated interior opening, or nephrostome, may also play a part in the collection of waste products, but it is believed to serve primarily for the collection of eggs or spermatozoa, which develop in the coelom. Ammonia is the chief nitrogenous excretory product.

Nervous System.—The central nervous system is of the annelidan type. Paired cerebral ganglia form a bilobed brain that is situated above the pharynx and closely associated with the special sense organs. The brain may lie superficially beneath the skin, as in *Golfingia verrilli*, or it may be more or less deeply sunken at the bottom of a cephalic tube that communicates with the exterior by a small opening above the tentacles. The development of the cephalic tube is probably an adaptation to burrowing; it reaches an extreme condition in species like *Sipunculus nudus*, which may dig themselves down to nearly a metre in loose sand. In addition to the neurons of the special sense organs, the brain receives sensory nerves from the tentacles and sends motor nerves to the retractor muscles of the introvert. Circumpharyngeal connectives unite the brain with the ventral nerve cord, which is ganglionated along its whole course and gives off mixed nerves to the body wall. There is no evidence of segmentation. The speed of conduction in the ventral cord approaches that of the somatic motor nerves of cold-blooded vertebrates, 10–20 cm. per sec.

Sense Organs.—The surface of the body responds to both tactile and chemical stimuli; sense organs vaguely resembling taste buds are located in the skin papillae and may contain both sensory neurons and gland cells.

There are three main special sense organs: (1) The cerebral or (miscalled) frontal organ, a lobe of the brain that projects forward and is united with an epithelial cushion at the base of the cerebral tube or depression. The function of the cerebral organ is unknown. (2) The nuchal organ, a ciliated paired or quadripartite raised area, resembling the organ of this name in polychaete annelids, is present in some genera, above the cerebral organ. Although well innervated, the nuchal organ serves an unknown function. (3) Paired eyes are present in sipunculid larvae and persist in the adults of various species. In the larva they are simple pigment spots associated with the future brain; in the adult they may disappear or, if present, may become deeply sunken at the bottom of ocular tubes that lie embedded in the brain and are closed to the exterior by cuticular plugs. Within the ocular tubes, a secretion forms a lenslike body. Neurons from sensory cells at the base of the eye communicate by a direct reflex pathway with the motor nerves of the retractor muscles. Retraction in response to a light stimulus is very rapid in species that have a well-developed lens.

Reproductive Organs.—The sexes are separate but externally similar. Rare instances of hermaphroditism have been described. The gonads are attached at the origin of the retractor muscles to the body wall and are of various forms. In *Sipunculus* there are paired branching glands on little stalks; in *Dendrostomum* there is a single transverse ridge. The sex cells are shed into the coelom at an early stage and grow to maturity, nourished by the coelomic fluid. The eggs are usually spherical, but in *Phascolosoma* they are flattened. The nephridia function as ducts to provide passage of the sex cells.

Development.—Segmentation is of the annelidan-molluscan type, with spiral cleavage. The blastopore forms the mouth; the anus develops later and is situated somewhat dorsally from the very beginning. As in Annelida (*q.v.*) the mesodermal bands are formed by teloblasts derived from blastomere 4d, and the coelom forms later as a schizocoele (*see* EMBRYOLOGY AND DEVELOPMENT, ANIMAL).

Fossil Remains.—It is doubtful whether any of the remarkable Middle Cambrian forms, some of which were referred by C. D. Walcott to the Gephyrea, can be regarded as sipunculids, since the intestine, when preserved, appears to be straight. An equally dubious gephyrean worm, *Epitrachys*, was described by E. Ehlers (1868) from the lithographic shales of Germany (Mesozoic). Tertiary, and even Paleozoic Devonian corals are said to have basal deformities resembling those produced by the living genus *Aspidosiphon*.

Relationships.—There can be no doubt that sipunculids have pronounced annelidan affinities, despite the lack of segmentation. Hyman regards them as protostomatous coelomates placed along the main evolutionary line of the Protostomia that leads to An-

nelida, Mollusca, and Arthropoda. Molluscan relationships have also been claimed on embryological grounds.

Classification.—W. K. Fisher (1952) recognizes 13 genera comprising, according to Hyman, some 250 valid species. Fisher's invaluable revision necessitated changes in names that had become well established in the literature. Species formerly placed in the genus *Phascolosoma* are correctly assigned to the genus *Golfingia*, whereas the name *Phascolosoma* is properly applied (for reasons of priority) to species of the obsolete genus *Physcosoma*. J. H. Gerould suggested that species of the genus *Golfingia* ("*Phascolosoma*") provide an ancestral group whose members became specialized in different directions. Three genera (*Aspidosiphon*, *Lithacrosiphon*, and *Cloeosiphon*) possess a preanal shield or cone; *Aspidosiphon* has also an apical shield. In most of the remaining genera the tentacles surround the mouth, but in *Phascolosoma* ("*Physcosoma*") they form a horseshoe enclosing the nuchal organ, dorsal to the mouth. Several genera are characterized by the division of the longitudinal musculature into separate bands and in four of these (*Sipunculus*, *Xenosiphon*, *Siphonomecus*, and *Siphonosoma*) there are integumentary coelomic canals; in *Siphonides* these bands are absent. The body musculature forms a continuous sheet in the remaining genera: these include *Golfingia* (except the subgenus *Phascolopsis*); *Dendrostomum*, with branched tentacles; and two genera (*Phascolion* and *Onchnesoma*), which, among other peculiarities, have only a single nephridium.

BIBLIOGRAPHY.—L. H. Hyman, *The Invertebrates*, vol. v (1959), is indispensable and supersedes the earlier, but still interesting, reviews by F. Baltzer in Kukenthal and Krumbach's *Handbuch der Zoologie*, vol. 2, pt. 2 (1931) and W. Harms in *Handw. Naturwiss.*, 2nd ed., vol. 9 (1934). A revision of the genera, with keys for their identification, is given by W. K. Fisher in "The Sipunculid Worms of California and Baja California," *Proc. U.S. Nat. Mus.*, vol. 102, pp. 371–450.

(G. E. P.)

SIQUEIROS, DAVID ALFARO (1896–), youngest of the "big three" of 20th-century Mexican mural painters (the others being José Clemente Orozco and Diego Rivera; *qq.v.*), was born in Chihuahua on Dec. 29, 1896. Although he signed his painting "Siqueiros," his true patronymic was Alfaro. A sublieutenant in the Constitutionalist Army at the age of 15, Siqueiros had already entered upon a lifelong dual career as artist and militant propagandist. In Paris from 1919 to 1921, he later visited the U.S.S.R., the U.S. and various Latin-American countries. In the 1920s he helped to found the Mexican magazine *Machete*. During the Spanish Civil War of 1936–39 he served in the Republican Army.

Alone or with organized groups of colleagues, Siqueiros produced thousands of square metres of vivid wall paintings, indoors and outdoors, commonly using synthetic lacquer colours sprayed from paint guns to produce his powerful, brightly coloured effects. In his studio paintings as well as on public walls, he portrayed social, political, and industrial change and ferment with a dazzling mixture of photographic realism, illusion, and fantasy. His most persuasive and permanent murals are to be seen at the headquarters of the Electrical Workers' Syndicate, the Palace of Fine Arts, the Polytechnic Institute, the National University, the nurses' home at Social Security Hospital No. 1, all in Mexico City, and at Chillán in Chile. Scores of his easel paintings—signed "*El Coronelazo*" after 1943—are in private collections and museums, notably the Museum of Modern Art in New York City.

SIRACH: *see* ECCLESIASTICUS.

SIRAJ-UD-DAULA (d. 1757), ruler of Bengal under the nominal suzerainty of the Mughal emperor of India. The date of his birth is generally placed between 1729 and 1736. His name was Mirza Mahmud, and he succeeded his grandfather Ali Vardi Khan as nawab of Bengal on April 9, 1756. He was inexperienced, capricious, and vacillating. On hearing that the English were fortifying Calcutta against the French, he attacked and took the city after a slight resistance on June 20, 1756. The governor and many senior merchants had deserted to ships; the survivors of the garrison were secured for the night in the Fort William lockup known as the "Black Hole," where many were suffocated. There is no reason to suppose that the nawab was personally responsible for this incident, which was rather the result of ignorance and apathy than of deliberate cruelty. (*See* CALCUTTA.)

Calcutta was recaptured by Robert Clive and Adm. Charles Watson on Jan. 2, 1757. In February Siraj-ud-daula made peace with the East India Company, restoring its privileges. Cowed by an Afghan incursion into northern India, he allowed Clive to capture the French settlement of Chandernagore without interference. Thus strengthened, Clive joined a conspiracy of discontented nobles headed by Mir Jafar, Siraj's principal general. Siraj was overthrown at the Battle of Plassey on June 23. He fled up-country to Rajmahal but was captured and executed on July 2, 1757, by Mir Jafar's son Miran.

See *Cambridge History of India*, vol. v, ch. vii; Brijen K. Gupta, *Sirajuddaullah and the East India Company 1756–57* (1962).

(T. G. P. S.)

SIRENIA, an order of aquatic placental mammals, comprising the manatees (*Trichechus*), the dugongs (*Dugong*), the extinct (since the 18th century) Steller's sea cow (*Hydrodamalis*), as well as their fossil relatives of the Tertiary Period. The torpedo-shaped body ends behind in a horizontal tail fluke, as in the dolphins; but in contrast with the latter the broad muzzle is truncate and the transversely expanded lips are very mobile. The name Sirenia was given in allusion to the supposed resemblance of these animals to mermaids. A dugong as seen at a distance from the deck of a ship and especially if floating half upright, with its baby under its flipper, might well be mistaken for a mermaid; and many legends gathered around them in the early days of exploration of the Indian Ocean. For the evolutionary history and relationships of the Sirenia, *see* UNGULATE. *See* also DUGONG; MANATEE; SEA COW.

SIRENS, in Greek mythology, creatures half-bird half-woman who lured sailors to destruction by the sweetness of their song. Homer describes how Odysseus, advised by Circe, escaped the danger yet heard the songs by stopping the ears of his crew with wax so they were deaf to the Sirens and having himself tied to the mast so he could not steer the ship out of course. Apollonius Rhodius tells how when the Argonauts sailed that way Orpheus sang so divinely that none of them listened to the Sirens. Later legend relates that after one or other of these failures the Sirens committed suicide. According to Homer there were two Sirens, living on an island in the western sea between Aeaea (Circe's home) and the rocks of Scylla. Later the number was usually increased to three, and they were located on the west coast of Italy, near Naples. They are variously said to be the daughters of the sea-god Phorcys or of the river-god Achelous. Plato in the myth of Er (*Republic* 10) places a Siren in each of the eight musical spheres. In art they appear first as birds with the heads of women, later as women, sometimes winged, with bird-legs.

The Sirens seem to have evolved from two elements: a primitive tale of the perils of early exploration combined with an Oriental image of a bird-woman. Anthropologists explain the latter as a soul-bird; *i.e.*, a winged ghost which steals the living to share its fate. In this respect the Sirens have affinities with the Harpies (*q.v.*). The Sirens continued to exist in folklore throughout the medieval period and later, sometimes being thought of as fish-women rather than bird-women.

See Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, 2nd series, vol. 3, col. 288–308 (1927). (H. W. PA.)

SIRICIUS, SAINT (*c.* 334–399), pope from 384 to 399, was a Roman by birth. In spite of the antipope Ursinus, Siricius was unanimously elected pope in December 384. He often followed the lead of St. Ambrose (*q.v.*), but was conscious that he bore "the burdens of all who are burdened, or rather, the Blessed Apostle Peter carries them in our person," as he wrote to Himerius bishop of Tarragona, in answer to disciplinary questions. These responses are the earliest surviving texts of papal decretals. St. Jerome's departure from Rome, while not forced by Siricius, was not unwelcome to him. Jerome's later activities in anti-Origenism displeased the pope. Ambrose and Siricius ended the Meletian controversy at Antioch by recognizing Flavian as patriarch. Al-

though he opposed Priscillianism and other errors, Siricius disapproved of Catholic extremists. Siricius was pope when the emperor rebuilt the basilica of St. Paul; a still surviving column commemorates Siricius' dedication. His feast day is Nov. 26. (W. M. K.)

SIRIONO INDIANS, a group of seminomadic, Guaraní-speaking aborigines who originally lived in isolated pockets of tropical forest land in eastern Bolivia. Of a population of about 2,000 in the 1960s less than a third still roamed the forests near the Río Blanco, the Río Grande, and the Río Piray. The remainder lived in missions or under conditions of forced labour on farms and cattle ranches in the political departments of the Beni and Santa Cruz.

Few tribes of the world are more technologically handicapped than the Siriono in their native state. Their only weapon is a cumbersome bow and arrow; their only tool, a digging stick of palm. They live almost exclusively by hunting and by gathering wild fruits and nuts, although occasionally maize (corn), cassava, and papaya are planted in natural clearings in the forest. They wear no clothing and live on the margin of subsistence the year round. They are not warlike, being preoccupied with food getting. The aged and infirm are sometimes abandoned, as is the house when a person dies.

The Siriono are organized into endogamous bands of from 60 to 100 persons. An entire band lives in a single hut, a crude, roughly rectangular palm shelter providing little resistance to wind and rain. Within the hut the matrilineal family groups cluster around a series of hammocks and hearths.

In part because of the difficult nature of supplying sufficient food for survival, ceremonial, aesthetic, and religious life is not highly elaborated among the Siriono. A form of ring dance is practised but no other forms of art are developed. Religion is highly animistic, centred on a fear of evil spirits and monsters.

See also Guaraní.

Schermair, *Vocabulario sirionó-castellano* (1958); R. Needham, "Descent, Category, and Alliance in Sirionó Society," *Southwestern Journal of Anthropology*, vol. 20 (1964). (A. R. Ho.)

SIRIUS (the Dog star) is the brightest star of the constellation Canis Major (*q.v.*); it is also visually the brightest star in the heavens. Intrinsically, it is a normal blue star 21 times as luminous as the sun; it is somewhat larger than the sun and has a considerably higher surface temperature. Its apparent brilliance in the skies is mainly because of its relative nearness to Earth. The distance of Sirius from the solar system is 8.6 light-years, which is only twice the distance of the nearest known star beyond the sun. (*See* also Star.)

Sirius was known as Sothis to the Egyptians, who early in their history were aware that this star made its first appearance of the season in the twilight before sunrise at about the time when the annual floods were beginning in the Nile delta. The Egyptians long believed that Sothis caused the Nile floods and accordingly was the "creator of all green growing things," as a Pyramid text declares. They discovered that the heliacal risings of the star occurred at intervals of 365¼ days rather than the 365 days of their calendar year, a correction incorporated by Julius Caesar (in 45 B.C.) by use of the plan of leap years in his reform of the Roman calendar. Among the Romans the hottest part of the year was associated with the heliacal rising of the Dog star, a connection that survives in the modern expression "dog days."

The fact that Sirius is a binary star was reported in 1844 by F. W. Bessel at Königsberg. He had observed that the bright star was pursuing a wavy course among its neighbours in the sky instead of going ahead uniformly in a straight line, as a single star would do. Bessel concluded that Sirius had a traveling companion, with which it revolved in a period of about 50 years. This discovery constituted the first chapter in what came to be known as the "astronomy of the invisible"; *i.e.*, the detection of unseen celestial bodies by their effects on visible bodies. The discovery of the planet Neptune two years later by its gravitational effects on Uranus was another famous example. Whereas Neptune was sighted soon after its place in the sky was predicted, the companion of Sirius waited nearly 20 years for direct telescopic verification. The companion was first seen in 1862 by Alvan Clark, a U.S. telescope maker who was using the bright star for testing the lens of the 18½-in. refractor now at the Dearborn observatory.

Sirius and its companion revolve together, once around in 49.9 years, in orbits of considerable eccentricity and with average separation of the stars equal to the distance of Uranus from the sun. Despite the glare of the bright star, the 8th-magnitude companion is readily seen with a large telescope except when the two appear closest together, as they did in 1944. The two stars are respectively 2.3 and 1.0 times as massive as the sun. Although the companion has one-third the mass of Sirius and about the same surface temperature, its light is only $\frac{1}{10,000}$ as bright as that of the brilliant star. The conclusion seemed inescapable that the companion has the mass of a star, the size of a planet and therefore a density many thousand times the density of water. Although so high a density of matter seemed surprising at that time when little was known about atomic structure, a test of the conclusion was available from the theory of general relativity. Albert Einstein showed that the lines in the spectrum of a star should be displaced to the red by an amount that is directly proportional to the cube root of the star's mean density. Small enough in the case of the sun to be masked by other factors, this displacement would be conspicuous in the spectrum of an extremely dense star.

W. S. Adams reported (1925) on his observations of the spectrum of the companion of Sirius. He had found the lines displaced in the predicted direction, but by an amount somewhat different than might be expected. It may be that the diffused light of the bright star was confused in the spectrum with that of the companion. Later, D. M. Popper studied the spectrum of another excessively dense star, the 9th-magnitude white dwarf companion of the star 40 Eridani; he reported a red shift of the lines in satisfactory agreement with the shift that would be predicted from the calculated density in this case. *See* also references under "Sirius" in the Index. (R. H. Br.)

SIRMUR (Sirmoor), a district in the southern part of Himachal Pradesh, India, situated in the lower ranges of the Himalayas between Punjab on the west and Uttar Pradesh on the east. Area 1,095 sq.mi. (2,836 sq.km.). Pop. (1961) 197,551. Sirmur is hilly except in the southeast where the Giri River, which traverses the district from northwest to southeast, has its confluence with the Jumna. Chaur Peak, on the northern border, is about 12,000 ft. (3,660 m.) above sea level. In British India Sirmur was a princely state forming part of the Punjab Hill States; it was merged with Himachal Pradesh in 1948. It was also called Nahan after its chief town (pop. [1961] 12,439), which lies about 60 mi. (95 km.) S of Simla. (S. Gl.)

SIROCCO: *see* Wind.

SIROHI, a town in the southwest of Rajasthan, India, and the administrative headquarters of the district of the same name, lies 95 mi. (150 km.) S of Jodhpur on the main Delhi-Bombay railway via Ahmedabad. Pop. (1961) 14,451. The town is noted for the manufacture of knives and sword blades.

Sirohi District has an area of 1,979 sq.mi. (5,126 sq.km.) and a population (1961) of 352,303. Formerly a princely state, it was merged with Bombay in 1949 but ethnic considerations led to its being transferred to Rajasthan in the following year. The district is much broken up by hills and rocky ranges and the Aravalli Range crosses it from northeast to southwest. About 12 mi. (19 km.) SW of Sirohi town is Mt. Abu (*q.v.*). Much of the district is covered with jungle, which is abundant in wildlife. The climate is on the whole dry and healthy, and there is a general freedom from epidemic diseases. On Mt. Abu the average annual rainfall is about 64 in. (1,626 mm.); at Erinpura, less than 50 mi. (80 km.) to the north, it is only 13 (330 mm.) in. (S. M. T. R.)

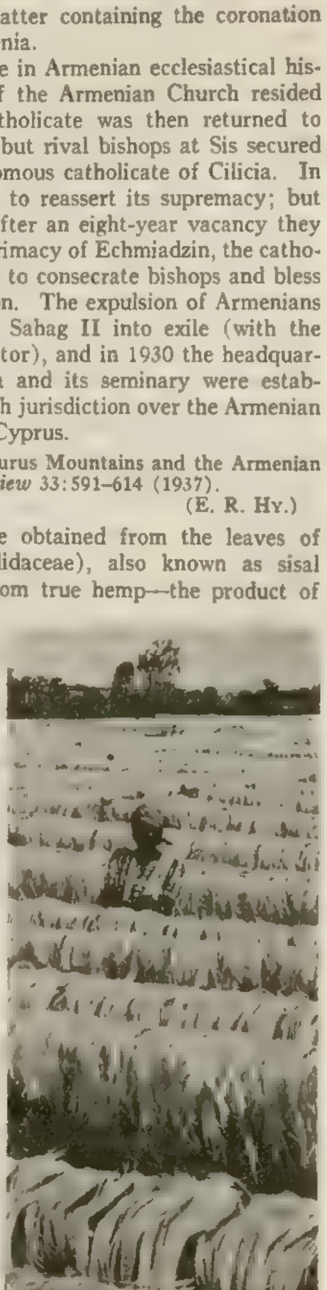
SIS (now Kozan), the former capital city of Armenian Cilicia, and now the chief town of a *kaza* in the Adana (Seyhan) *il* (province) of Turkey. Pop. (1960) 15,129. It lies on the Kirksu, a tributary of the Ceyhan River (ancient Pyramus), at the southern

end of a group of passes leading from the Anti-Taurus valleys to the Cilician plain and to Adana, which lies 40 mi. (64 km.) SW by road. First mentioned in Byzantine history as a frontier fortress unsuccessfully besieged by the Arabs in 704, Sis changed hands between Byzantines and Muslims until in the 12th century Leo II of Armenian Cilicia transferred his capital to that place from Anazarbus and erected many new buildings (*see* ARMENIA: *History*). It suffered frequent attacks from the Mamelukes of Egypt who finally occupied it in 1375. In 1488 it was taken by the Turks, and never recovered its prosperity; it is now in effect only a large village with a few thousand inhabitants. The castle and cathedral erected by Leo II survive, the latter containing the coronation chair of the kings of Lesser Armenia.

Sis has had a considerable place in Armenian ecclesiastical history. The supreme catholicos of the Armenian Church resided there from 1294–1439. The catholicate was then returned to Echmiadzin in Greater Armenia, but rival bishops at Sis secured recognition as heads of an autonomous catholicate of Cilicia. In 1885 the clergy at Sis attempted to reassert its supremacy; but when the see was filled in 1902 after an eight-year vacancy they were again obliged to accept the primacy of Echmiadzin, the catholicos of Cilicia retaining the right to consecrate bishops and bless the holy chrism for his jurisdiction. The expulsion of Armenians in 1915–20 drove the catholicos Sahag II into exile (with the relics of St. Gregory the Illuminator), and in 1930 the headquarters of the catholicate of Cilicia and its seminary were established at Antilyas, near Beirut, with jurisdiction over the Armenian Churches in Lebanon, Syria, and Cyprus.

See E. H. King, "Through the Taurus Mountains and the Armenian Cilician Kingdom," *The Asiatic Review* 33:591–614 (1937).
(E. R. HY.)

SISAL FIBRE, a hard fibre obtained from the leaves of *Agave sisalana* (family Amaryllidaceae), also known as sisal hemp. It is entirely different from true hemp—the product of *Cannabis sativa,* which is soft fibre. A closely related plant, *Agave fourcroydes,* produces the henequen fibre of Yucatán and Cuba, known in the trade as Yucatán sisal and Cuban sisal. Both sisal and henequen are indigenous to Mexico, but the East African colonies, Indonesia, and Haiti are the main sources of supply of true sisal fibre.



AUTHENTICATED NEWS

SISAL FIBRE (AGAVE SISALANA) BEING DRIED IN THE SUN, KENYA, AFRICA

The common century plant (*Agave americana*) suggests the habit of sisal and henequen. Both of these plants consist of a large rosette of rigid, straight, fleshy leaves arising from a short trunk. The sisal leaves are dark green in colour and have a terminal spine but ordinarily no marginal prickles. The life period of this plant is from 5 to 10 years. The henequen plant has grayish-green leaves which bear both a terminal spine and marginal prickles. The life period of this plant is from 15 to 25 years. Both sisal and henequen, when mature, produce a flower stalk or pole which develops from the centre of the leaf cluster and grows to a height of 15–25 ft. The light-yellow flowers are borne in dense clusters at the ends of the lateral branches.

The flowers of the sisal plant are followed by small bulbils, and those of the henequen plant by both bulbils and seed pods. The plants die after flowering. Both sisal and henequen may be propagated either from the bulbils or from suckers that grow from the rootstocks.

In harvesting, the lower mature leaves are cut off at the base, the spines and prickles are removed, and the leaves are carried in bundles to the cleaning machines. The cleaning of these fibres is a scraping process in which the leaves as they pass through the machine are carried over curved metal plates and are scraped by rapidly revolving scraping wheels that remove the pulp and waste material. The fibre is then dried either in the sun or by artificial drying methods, is sometimes brushed, and is then graded and baled for market.

These fibres are white to yellowish-white in colour, strong, flexible and in value for cordage purposes are second only to abacá. Henequen is used principally for the manufacture of binder twine, while sisal is used for binder twine and many other types of cordage. These fibres have a limited use in the manufacture of coarse fabrics. *See* also FIBRE. (H. T. ES.)

SISINNIUS, a Syrian, was pope from *c.* Jan. 15 to Feb. 4, 708.

SISKIN (ABERDEVINE), a canarylike bird, *Carduelis spinus,* which has long been known in England as a cage bird, is one of the finches (*q.v.*). It often feeds upon the catkins of alder or birch, frequently hanging upside down like a titmouse. Above, the male is olive green marked with black and yellow, and beneath, yellowish-white marked with black. The hen is grayer and streaked with white on its underparts. The male's song is a rapid musical twitter pierced with high squeaky call notes. The siskin breeds locally throughout Europe, and its range stretches across Asia to Japan.

Coniferous woods and thickets are favoured as nest sites. The nest of the siskin is like that of the goldfinch, but not so neatly built; the eggs, except in their smaller size, resemble those of the greenfinch.

A larger and more brightly coloured species, *C. spinoides,* inhabits the Himalayas. In the United States the name siskin or pine siskin is sometimes used for the pine finch (*Spinus pinus*).

SISLEY, ALFRED (1839–1899), one of the creators of French Impressionism, was born in Paris of English parentage on Oct. 30, 1839. Originally intended for commerce, Sisley began painting as an amateur, and it was in Gleyre's studio in 1862 that he began to associate with Monet, Renoir, and Bazille. The Franco-Prussian War of 1870, which brought financial ruin to the Sisley family, caused Sisley himself to flee temporarily to London, and it was at this period of crisis that he decided to make painting his full-time career. The remainder of his life was a constant struggle against poverty. He died at Moret-sur-Loing on Jan. 29, 1899, without ever having acquired the French citizenship for which he had applied some four years earlier. Shortly after his death his talent began to be widely recognized.

Sisley was essentially a landscape painter, whose early style was much influenced by Corot, and his restricted and delicate palette continued to reflect something of Corot's silvery tonalities; his snowscapes are particularly effective. Much of his best and most spontaneous work was done in the period 1872–80 in the neighbourhood of Paris, at Marly, Louveciennes, Bougival, Sèvres, Saint-Cloud, and Meudon, at a time when he was in close touch with Monet.

See J. Rewald, *The History of Impressionism,* 2nd ed. (1961); F. Daulte, *Sisley: Catalogue raisonné de l'oeuvre peint* (1959).

SISMONDI, JEAN CHARLES LÉONARD DE (1773–1842), Genevan economist, historian, and author of works representing a humanitarian protest in a materialistic age, was born in Geneva on May 9, 1773. His name was Simonde, but he italianized it, claiming Italian ancestry. Because of the revolutionary disturbances of 1793–94, his family fled to England (1793) and then to Italy (1794), settling on a little farm near Pescia, Tuscany. Sismondi's interest in agricultural problems, especially *métayage,* resulted in his descriptive *Tableau de l'agriculture toscane* (1801), published after returning to Geneva in 1800.

In 1803 he met Mme de Staël (*q.v.*); he became one of her regular guests at Coppet, and accompanied her to Italy (1805). He became the intermediary between Coppet and the *salon* of the countess of Albany (*q.v.*) at Florence, Mme de Staël and the countess sharing his aversion to Napoleon. However, when Na-

poleon proposed his *Acte additionnel* (1815), projecting a new liberal constitution for France, Sismondi, hoping that some of the achievements of the Revolution could be saved, supported him publicly. As professor of philosophy (1809) and history (1820) at the Académie de Genève, he devoted his life to research and writing. He died at Chêne, near Geneva, on June 25, 1842.

As an economist, Sismondi began by following Adam Smith (*q.v.*) with *De la richesse commerciale* (1803). Later, especially in *Nouveaux Principes d'économie politique* (1819), he was concerned less with theoretical economics than with the well-being of the people, which, in his view, should be the principal object of every government. Interest in social affairs is typical also of his immense *Histoire des Français* (31 vol., 1821–44; Eng. trans. 1849–50). It is less lively and original, however, than his *Histoire des républiques italiennes du moyen âge* (in part, 1807; in 16 vol., 1809–1818; Eng. trans. 1831), which brought him fame and many friendships. Fired with love of liberty and mankind, this work, in which medieval Italy is seen as the origin of modern Europe, helped the Italians to regain their national consciousness: such patriots as Foscolo, Mazzini, Manzoni, and Cavour regarded Sismondi with grateful admiration. *De la littérature du midi de l'Europe* (1813; Eng. trans. 1823), based on lectures at Geneva, and influenced by Mme de Staël's *De la littérature* (1800), was a useful synthesis of the Romance literatures. Sismondi also wrote on contemporary issues, such as the Negro slave trade, Italian and Greek independence, and the Algerian expedition of 1840.

BIBLIOGRAPHY.—Sismondi's journals and correspondence have been published by C. Pellegrini, 4 vol. (1933–54). The most complete biography is J. R. de Salis, *Sismondi, 1773–1842*, 2 vol. (1932). Monographs include A. Aftalion, *L'Oeuvre économique de Simonde de Sismondi* (1899); E. Halévy, *Sismondi* (1933); A. Amonn, *Simonde de Sismondi als Nationalökonom*, 2 vol. (1945–49); L. de Rosa, *Gian Carlo Sismondi e la sua opera* (1947); H. O. Pappe, *Sismondis Weggenossen* (1963). (CA. PE.)

SISTERHOODS, in the Christian Church, communities of women living and working together for specific religious purposes. See MONASTICISM; WOMEN'S RELIGIOUS ORDERS; ORDERS AND CONGREGATIONS, RELIGIOUS; *Roman Catholic Religious Orders of Women.*

SISYPHUS, in Greek mythology, the cunning king of Corinth who was punished in Hades by being made repeatedly to roll up a hill a huge stone which always rolled down again as soon as he had brought it to the summit. This fate is related in the *Odyssey*. In the *Iliad* Sisyphus, living at Ephyre (later Corinth), is the son of Aeolus (eponymous ancestor of the Aeolians), the father of Glaucus, and the grandfather of Bellerophon. In post-Homeric times he is called the father of Odysseus, cunning obviously providing the link between them. Sisyphus was reputed to have founded the Isthmian Games in honour of his relative Melicertes (*q.v.*). Later legend tells how when Death came to fetch him, Sisyphus chained him up so that no one died until Ares came to free Death and Sisyphus had to submit. But he had told his wife, Merope, not to perform for him the usual sacrifices, so when he reached the underworld he received permission to return and punish her for the omission. Once back at home, he continued to live to a ripe old age before dying a second time. Sisyphus is, in fact, like Autolycus and Prometheus (*qq.v.*), that widely popular figure of folklore, the trickster, or master thief. How he came by a royal genealogy is unknown. That he is everlastingly punished in Hades is presumably the recompense for his cheating Death, but why he is set to roll a great stone incessantly is a puzzle to which no convincing answer has yet been given. It appears to belong with other Greek imaginings of the world of the dead as the scene of fruitless labours. But Albert Camus, in *Le Mythe de Sisyphe* (2nd ed. 1949; Eng. trans. 1955), applies a contrary interpretation to that of classical antiquity. To him Sisyphus' task is typical of human endeavour, and its apparent futility should occasion the toiler happiness. (H. W. PA.)

SITAPUR, a town in the Lucknow division of Uttar Pradesh, India, and the administrative headquarters of the district of the same name, lies on the Sarayan River, 50 mi. (80 km.) NNW of Lucknow. Pop. (1961) 53,884. It has a cantonment and is a junction of the Northern and North-Eastern railways. There is considerable grain trade and the plywood manufactured in the town has an extensive market. Sitapur also has a well-equipped eye hospital.

SITAPUR DISTRICT, situated on the left bank of the Gumti (Gomati) River, has an area of 2,236 sq.mi. (5,791 sq.km.) and a population (1961) of 1,608,057. It is a vast plain, well wooded and well cultivated except in those parts where the soil is barren and cut up by erosion gullies. Its principal rivers are the Gogra and the Sarda. The main crops are wheat, rice, and barley. Khairabad, 5 mi. (8 km.) SE of Sitapur, is known for its many temples, mosques, and shrines. Biswan, 20 mi. (32 km.) E of Sitapur, has a sugar factory. (B. SI.)

SITKA (formerly NEW ARCHANGEL), historically the most notable settlement of Alaska, U.S., on the west coast of Baranof Island, in Sitka Sound. The city is on an island-studded and mountain-locked harbour, with a background of forest and snow-capped mountain cones; an extinct volcano, Mt. Edgecumbe (3,201 ft. [976 m.]), on Kruzof Island, is a conspicuous landmark in the bay. Monthly mean temperatures range from 33° F (1° C; January) to 56° F (13° C; August). Normal rainfall is 86 in. (2,185 mm.) and annual snowfall averages 26 in. (660 mm.).

Old Sitka or Ft. Archangel Gabriel, 6 mi. from the present town, was founded in May 1799 by Aleksandr Baranov, first Russian governor of Alaska. The fort was destroyed by the Tlingit Indians in 1802; the present town was founded in September 1804 when Baranov moved his headquarters there from Kodiak. Commonly known by its Indian name, Sitka, probably the name of a local tribe or village, it was the headquarters of the Russian-American Company until 1867. It was the leading trading post of Alaska and had shipyards, sawmills, flour mills, foundries and other industrial establishments. The formal transfer of Alaska to the U.S. took place at Sitka on Oct. 18, 1867. From 1867 until 1906 Sitka was the capital of Alaska. The modern industries are logging and lumber manufacture, and fishing and fish processing. There are salmon canneries, facilities for cold storage and processing of halibut, salmon, and other fishery products, and a large fishing fleet.

The public schools are attended by both whites and Indians of the Tlingit tribe. The Presbyterian-supported Sheldon Jackson High School and Junior College are accredited schools. Other institutions include the Alaska Pioneers Home for aged residents of the state; Sitka National Monument, a 54-ac. natural park; Sitka National Cemetery; Sheldon Jackson Ethnological Museum; Magnetic and Seismological Observatory of the Coast and Geodetic Survey; St. Peter's by the Sea (Episcopal, 1899); Lutheran Church (1840, the first Protestant church in Alaska); Presbyterian and Roman Catholic churches. Historic St. Michael's Cathedral (Russian Orthodox, 1848) was destroyed by fire in 1966.

On 475-ac. Japonski Island, in the harbour, the federal Alaska native service established the Mt. Edgecumbe Vocational Boarding School, a tuberculosis sanatorium, and the Mt. Edgecumbe Orthopedic Hospital, maintained jointly with the state of Alaska.

The population at the 1960 census was 3,237. (J. E. CL.)

SITTANG, a river of Burma rising in the Yamethin district and flowing south for about 350 mi. (560 km.) in a broad valley between the forested Pegu Yoma on the west and the sharp edge of the Shan Plateau on the east before emptying into the Gulf of Martaban. Geomorphologists believe that the upper Irrawaddy, north of Mandalay, originally flowed due south along the Sittang Valley but was deflected by earth movements in Pleistocene times, beheading the old lower course which became the Sittang, a misfit stream of small volume occupying a large valley. Too shallow to be important for navigation, the river is used to float down quantities of timber, especially teak. Its valley is followed by the main railway and road from Rangoon to Mandalay, and the towns of Pyinmana and Toungoo lie near its banks. (L. D. S.)

SITTARD, a town of the southeastern province of Limburg, Neth., lies 13 mi. (21 km.) NE of Maastricht. Pop. (1960) 27,548. Fertilizers, chemicals, electronic tubes, and textiles are produced and there are coal mines in the area. The town is a railway junction and on the Maastricht–Roermond motorway. Excavations at two nearby villages have shown the remains of Danubian

culture (4200–3800 B.C.). Sittard received its charter in 1243. From 1400 to 1794 it was a domain of the dukes of Jülich. After the period of French rule (1794–1814) it became part of the kingdom of the Netherlands and, apart from a period of Belgian rule in 1830–39, has since remained Dutch.

SITTER, WILLEM DE (1872–1934), Dutch astronomer and cosmologist, whose papers on relativity published in London during World War I brought Einstein's General Theory to the notice of British scientists, with important consequences for cosmology. De Sitter was born at Sneek, Friesland, Neth., on May 6, 1872. He studied at the University of Groningen to become a mathematician, but, on the invitation of Sir David Gill, her majesty's astronomer at the Cape of Good Hope, he spent two years (1897–99) at the Cape observatory, as a result devoting himself to astronomy thereafter. In 1908 he was appointed professor of astronomy at Leiden, and in 1918 he became director of the Leiden observatory. There he trained student astronomers, many of whom obtained important posts abroad, especially in the U.S. As a practical astronomer he established a station at Johannesburg to observe the southern sky and sent expeditions to stations near the equator in Kenya to determine fundamental declinations by azimuth observations of stars at low altitudes.

From the time of his visit to the Cape, De Sitter had studied the motion of Jupiter's four great satellites. Theoretical discussions published in 1918, 1919 and 1925 used observations dating from 1668 and included results obtained by him from several observatories. He died at Leiden on Nov. 20, 1934. (J. JN.)

SITTINGBOURNE AND MILTON, an urban district in the Faversham parliamentary division of Kent, England, formed in 1930 by the union of Milton Regis with Sittingbourne. Pop. (1961) 23,623. Area 7.7 sq.mi. It is on a navigable creek of the Swale, 38 mi. ESE of London by road. Sittingbourne consists principally of one long street, the Roman Watling street. Papermaking is its chief industry, brick and cement making and fruit preserving are also important, and as an agricultural market town it is the centre of the Kentish cherry-growing area. Sittingbourne is mentioned in Saxon documents in 989 and frequently in contemporary records of the 13th and 14th centuries. The first charter was obtained in 1573; a second in 1599.

From Roman until comparatively recent times Milton was a noted oyster fishery centre. It was a royal manor whose revenues formed part of the dowry of successive queens. An earthwork known as Castle Rough, in the marshes below Milton, was probably the work of Hasten the Dane in 892, and Bayford castle, 1 mi. distant, occupies the site of one said to have been built in opposition by King Alfred.

Tong castle, about 2 mi. E of Sittingbourne, consists of a high mound surrounded by a moat and is said to have been erected by Hengist (*q.v.*). The story of the founding of the castle resembles that connected with the city of Carthage. Vortigern is said to have granted Hengist as much land as an oxhide could encompass, and the hide being cut into strips the site of Tong castle was accordingly marked out. The same tradition attaches to Tong castle in Shropshire. Tradition also asserts, according to the 12th-century chronicler, Geoffrey of Monmouth, that it was in Tong castle that Vortigern met Rowena, Hengist's daughter, and became so enamoured of her as to resign his kingdom to her father.

SITTING BULL (*c.* 1831–1890), most famous chief of the Teton Dakota (Prairie Sioux) and perhaps the most famous of all American Indians, was born on Grand River, in what is now South Dakota, the son of Jumping Bull, of the Hunkpapa division of the Tetons. He joined his first war party at the age of 14 and, soon gaining a reputation for fearlessness in battle, became leader of the Strong Heart warrior society about 1856. Within five years he had extended the Sioux hunting grounds westward into what had been the territory of Shoshone, Crow, Assiniboin, and other Indian tribes. His first skirmish with white soldiers occurred in 1863, after the so-called Minnesota Massacre by Santee Sioux (*see* MINNESOTA: *History*) had involved the entire Sioux nation in trouble with the U.S. Army. For the next five years he was in frequent hostile contact with the Army, which was invading the Sioux hunting grounds and bringing ruin to an Indian economy based on the buffalo. In 1866 he became principal chief of the northern hunting Sioux, with Crazy Horse (*q.v.*), leader of the Oglala division, as his vice-chief.

In 1868 the Sioux made peace with the whites in exchange for a guaranteed reservation north of the North Platte River and the right to hunt off the reservation. The treaty was soon violated on Gen. George A. Custer's discovering gold in the Black Hills in 1874 and precipitating a rush of miners into the reservation area. Sitting Bull's continued defense of his people's hunting grounds and his refusal to be confined to the reservation led, in 1876, to a campaign against the Sioux commanded by Gen. George Crook. Summoned by Sitting Bull, the Sioux, with Cheyennes and some Arapahoes, met in a great encampment on the Rosebud River and in June engaged and defeated Crook. The camp then moved to the Little Bighorn River for game, and there on June 25 took place the battle in which Custer was killed (*see* CUSTER, GEORGE ARMSTRONG).

But though the Sioux might win battle after battle with the Army, they could never win the war. They depended on buffalo for their livelihood, and the buffalo, under the steady encroachment of the whites, were rapidly becoming extinct. Hunger led more and more Sioux to surrender, and in May 1877 Sitting Bull led his remaining followers across the border into Canada. But the Canadian government could not acknowledge responsibility for feeding a people whose reservation was south of the border, and after four years, during which his following dwindled steadily, famine forced Sitting Bull to surrender. After 1883 he lived at the Standing Rock agency, where he vainly opposed the sale of tribal lands. Hunger, disease, and, beginning about 1889, rumours of a coming Indian Messiah who would sweep away the whites (*see* GHOST DANCE) caused unrest among the Sioux. As a precaution, Indian police and soldiers were sent to arrest the chief. Seized on Grand River, Dec. 15, 1890, Sitting Bull was killed while his warriors were trying to rescue him.

Sitting Bull appears to have had qualities of leadership that were not common among Plains Indians, the power to make plans and to work steadily toward their accomplishment. Among the Sioux he was admired as a loving father of his people, a singer of songs, always affable and pleasant in manner, devoutly religious and a prophet whose prayers were strong.

For a portrait, *see* INDIAN, NORTH AMERICAN.

See Stanley Vestal (pseud.), *Sitting Bull: Champion of the Sioux*, new ed., with bibliography (1957). (W. S. C.; X.)

SITWELL, the name of an English family, three members of which achieved fame as writers in the first half of the 20th century. They are EDITH (1887–1964), (FRANCIS) OSBERT (1892–), and SACHEVERELL (1897–), the children of the antiquarian and genealogist Sir George Reresby Sitwell, 4th Bart. (1860–1943), and of Ida Emily Augusta Denison (d. 1937) daughter of Baron (later 1st Earl of) Londesborough. Edith was born at Scarborough, on Sept. 7, 1887; Osbert in London, on Dec. 6, 1892; and Sacheverell at Scarborough, on Nov. 15, 1897. They spent much of their childhood at Renishaw Hall, near Sheffield, the family seat in Derbyshire. A brilliant, eccentric, and domineering father, and a beautiful but erratic mother, who spoiled her sons but was harsh to her daughter, drove them often for understanding and affection to servants and governesses. Edith was educated privately; Osbert and Sacheverell at Eton and Osbert served in the Grenadier Guards (1912–19). All three showed a precocious interest in modern movements in art and literature, and, as soon as they could escape from parental influence, became writers. Dame Edith (she was created a Dame of the British Empire in 1954) is best known for her poetry; Sir Osbert for his prose memoirs; and Sacheverell for books on art, architecture, and travel.

Edith Sitwell's ambition to write was stimulated by reading Swinburne when she was 17 (she edited a selection of his poetry in 1960). From 1916 to 1921 she edited *Wheels*, an anthology of experimental poetry published as a counterblast to Sir Edward Marsh's *Georgian Poetry*. Her early poetry, well exemplified in her long *The Sleeping Beauty* (1924) and in the witty

series written for recitation with William (later Sir William) Walton's suite *Façade* (first performed 1922; enlarged 1926; definitive version 1942), combines a fanciful, sometimes brittle, quality with underlying melancholy, and with technical innovations and use of associative imagery derived from the French Symbolists. *Gold Coast Customs* (1929), expressing horror at the corruption of society, began a new period, and poems written during World War II—*Street Songs* (1942), *Green Song* (1944), *The Song of the Cold* (1945)—appealed to a wide public by their more sweeping rhythms and their expression of anguish at human cruelty, combined with faith in God's goodness and the holiness of Nature. This religious emphasis was continued in *Gardeners and Astronomers* (1953) and *The Outcasts* (1962). In 1955 she was received into the Roman Catholic Church. Critical and historical works include *Alexander Pope* (1930), *Aspects of Modern Poetry* (1934), *Fanfare for Elizabeth* (1946), and *The Queens and the Hive* (1962). *A Poet's Notebook* (1943) reveals wide reading and interest in technique. Her autobiography, *Taken Care Of*, was published in 1965, after her death (in London on Dec. 9, 1964). *Collected Poems* was published in 1930 and 1957; and *Façade and Other Poems, 1920–35*, in 1950.

Osbert Sitwell has written satirical and serious poetry (*Collected Satires and Poems*, 1931; *Mrs. Kimber*, 1937; *Selected Poems: Old and New*, 1943; *Wrack at Tidesend*, 1952; etc.); novels, of which the best is *Before the Bombardment* (1926), a satirical portrayal of the last phase of Victorian society in Scarborough just before World War I; short stories; and criticism, but his reputation rests on his autobiographical *Left Hand, Right Hand* (1944), *The Scarlet Tree* (1946), *Great Morning* (1947), *Laughter in the Next Room* (1948), and *Noble Essences* (1950). In these, which create with conscious nostalgia the portrait of a vanished age, the author's father is presented as a comic figure of heroic proportions, and the prose style blends delicacy with robust appreciation of the grotesque.

Sacheverell Sitwell's poetry—*The Rio Grande* (performed 1929, with music by Constant Lambert), *Dance of the Quick and the Dead* (1936), *Sacred and Profane Love* (1940), *Selected Poems* (1948), etc.—mainly in traditional metres, reveals in its mannered style the effects of his interest in the arts and music. More original are his imaginative and interpretative books on art, architecture, music, and travel, of which the first, *Southern Baroque Art* (1924), was the forerunner of much academic research. His poetic prose is seen at its best in the "autobiographical fantasia," *All Summer in a Day* (1926), and the gloomily meditative *Splendours and Miseries* (1943).

SIVAJI (SIVAJI BHONSLA) (1627–1680), Maratha hero, was the son of Shahji Bhonsla, a *jagirdar* (*i.e.*, holder of the right to collect the land tax from an assigned district) of the Muslim kingdom of Bijapur in the Deccan, India. Born at Shivner, Poona district, in April or May 1627, Sivaji succeeded his father in 1655 and followed his policy of increasing his territories and achieving independence. In 1659 he defeated the Bijapuri army and himself killed its general, Afzal Khan. Sivaji then turned against the Mughal territories, plundering Surat in 1664, but was brought to bay by the Mughal general Raja Jai Singh in 1665. An attempted settlement with the emperor Aurangzeb at Agra in 1666 broke down on account of mutual suspicions; Sivaji, placed under house arrest, escaped in a fruit basket and resumed his independent career in the Deccan. He plundered Surat again in 1670 and in 1674 crowned himself at Raigarh (Rajgarh, south of Poona) as an independent sovereign with mixed Mughal and Hindu symbolism. During 1676–78 he laid the foundations of Maratha power in the south. He died at Raigarh on April 5, 1680, the master of a compact and independent kingdom in western India.

Sivaji's organization of his kingdom was based on the functional integration of the three sections of the population, Brahmans, Marathas, and Prabhus, in defense of land and religion. Working on the Maratha love of independence he evoked a fierce regional nationalism which enabled the Marathas to withstand the onslaught of the emperor Aurangzeb (*q.v.*) during 1681–1707. *See* also MARATHA.

SIVAS (ancient MEGALOPOLIS-SEBASTEIA), a town and capital of the *il* (province) of the same name in central Turkey, lies at an altitude of 4,420 ft. (1,347 m.) in the broad valley of the Kizil Irmak, 220 mi. (350 km.) E of Ankara. Pop. (1960) 93,368. The climate is healthful but severe in winter with average January temperature −5° C (23° F). Sivas is an active trade centre; the chief manufactures are cement, coarse cotton cloth, and woolen socks. It stands at the junction of the Kayseri-Samsun-Malatya and Kars railways.

The *medresses* (colleges) in Sivas, built in the 13th century by the Seljuk sultans of Rum, are among the finest remains of Muslim art in Asia Minor. In one of them is the tomb of its founder, Izz ud-Din Kai Kaus I (1210–19). Near the town is the Armenian monastery of the Holy Cross, in which are kept the throne of Senekherim and other relics. Mekhitar, the founder of the Mekhitarists (*q.v.*) and of the well-known monastery at Venice, was born (1676) at Sivas.

Sivas, as Sebasteia, became the capital of Armenia Minor under Diocletian at the end of the 3rd century, and in the 7th century that of the Sebasteia Theme. Justinian I (483–565) rebuilt the walls and, under the Byzantine emperors, it was second only to Caesarea (Anazarbus) in size and wealth. In 1021 Senekherim, king of the Armenian province of Vaspurakan (Van), ceded his dominions to Basil II, and became the Byzantine viceroy of Sebasteia and the surrounding country. This position was held by his successors until the town fell into the hands of the Turkmen after the defeat of Romanus IV by the Seljuks (1071).

After having been ruled for nearly a century by the Danishmend amirs, Sivas was taken (1172) by the Seljuk sultan of Rum, and in 1224 was rebuilt by Sultan Ala ud-Din Kaikobad I. In 1400, when seized and plundered by Timur, the city is said to have had 100,000 inhabitants, and to have been famous for its woolen stuffs. Mohammed II the Conqueror (1451–81) restored the citadel, and the town was for many years an important Ottoman provincial capital. Early in the 19th century, like all other Ottoman towns, it was terrorized by janizaries (*q.v.*). In 1919 a national congress was held at Sivas, which eventually led to the revolution. (*See* also TURKEY: *History*.)

SIVAS IL is one of the largest provinces in Turkey. Area 10,999 sq.mi. (28,487 sq.km.). Pop. (1960) 669,922. To the west are the Ak Mountains, and the province is drained by the Kizil Irmak, Kelkit, Calti, and Tohma rivers. It is an important cereal-producing region and also contains mineral deposits, the chief being iron ore at Divrigi, about 80 mi. SE of Sivas town. The iron ore is mainly consumed by the iron and steel mills at Karabuk in Zonguldak province on the Black Sea. (N. TU.; S. ER.; E. TU.)

SIWAH, an oasis in As Sahra' al Gharbiyah *muhafaza* (Western Desert Governorate), Egypt (United Arab Republic), near the Libyan frontier and about 350 mi. WSW of Cairo. Also known as the oasis of Amon (Jupiter Ammon or Ammonium), its ancient Egyptian name was *Sekhet-am* (Palm land). Its chief town, also called Siwah, is at latitude 29° 12′ N, longitude 25° 30′ E. The oasis is about 6 mi. long by 4 to 5 wide, with a population (1958 est.) of 5,000. Ten miles northeast is the small oasis of Zaytun (Zeitun), and westward a chain of little oases and small salty pools extends for about 50 mi. Two rock outcrops provide the sites of the old walled ruins of Siwah and Aghurmi, veritable fortresses.

The inhabitants, who live in mud-brick houses at the foot of their old strongholds, are a mixture of Berber, Bedouin, and Sudanese; they are distinct from the Egyptians, being connected more closely with North Africa than the Nile Valley. They speak their own Berber dialect, although most of the men understand Arabic, and about 10% of the people are literate. The only properly developed industry is basketmaking. The oasis is extremely fertile, with about 200 springs, of which 80 are important.

Evidence suggests that in ancient times the area of cultivated land was greater than in modern times, but attempts to enlarge the agricultural area have failed, mainly through lack of labour. Many kinds of fruit and cereals are grown, although some food is imported. The export of dates and olive oil provides the chief source of income; there are about 40,000 olive trees and 200,000 date palms. Desert caravans for trading are rare since the introduction of motor transport and the building of the road connecting with the railway at Matruh.

The oasis owes its distinction to the oracle temple of Amon (*q.v.*), already famous in the time of Herodotus and consulted by Alexander the Great. The fragmentary remains of the temple, with inscriptions dating from the 4th century B.C., lie in the ruins of Aghurmi. The oracle fell into disrepute during the Roman occupation of Egypt. Half a mile from Aghurmi is the ruined temple of Umm Beda (Um Ebeida), of the same period, with reliefs depicting the prince of the oasis making offerings to Amon. There are many remains of the Roman period. The area of the Libyan frontier is dominated by the Senusi sect who formerly prevented various explorers from penetrating westward beyond Siwah. The first European to reach Siwah since Roman times was William George Browne, who visited the oasis in 1792. In 1910 a telegraph line was built across the desert from Alexandria to the oasis.

(A. B. M.)

SIWALIK HILLS (SIWALIK RANGE), the name commonly given to the whole belt of the Himalayan foothills extending for more than 1,000 mi. from the Tista River, Sikkim, through Nepal across northwestern India into the northern part of West Pakistan. Though sometimes only about 10 mi. wide and normally reaching elevations of only 2,000–3,000 ft., the range of hills rises abruptly from the Indo-Gangetic plains and separates them from the main range of the Himalayas. The Siwaliks are built up of soft sandstones, conglomerates, and shales of Late Tertiary Age and so belong to a late stage in the Himalayan folding. In places intermediate valleys, *duns*, occur between the Siwaliks and the outer Himalayas; *e.g.* Dehra Dun (Dehra Valley) between the Siwaliks and the Mussoorie Mountains. The Siwalik Range proper, to which the name was formerly restricted, is the 200 mi. of foothills from Hardwar on the Ganges (Ganga) northwestward to the Beas (Bias) River. Everywhere in this section the poor scrub forests have long since been removed and the hills are subject to spectacular erosion. Periodic floods sweep down masses of sand and silt in the everchanging *chos* (stream beds which are dry except after rains).

(L. D. S.)

SIXTUS, the name of five popes.

ST. SIXTUS I (Xystus), pope for nine or ten years in the second and third decades of the 2nd century, was the successor of Alexander I and thus the sixth bishop of Rome after St. Peter. He is commemorated on April 6.

ST. SIXTUS II (Xystus), pope from 257 to 258, succeeded Stephen I in August 257. He restored the relations with the African and Asian churches that had been severed by his predecessor on the question of heretical baptism. He suffered martyrdom under the emperor Valerian and is commemorated on Aug. 6.

ST. SIXTUS III (Xystus), pope from 432 to 440, succeeded Celestine I on July 31, 432. He had previously been suspected of favouring the Pelagians, but on becoming pope he disappointed their expectations and repelled their attempts to enter again into communion with Rome. The dispute between Cyril of Alexandria and John of Antioch, who had been at variance since the Council of Ephesus, was settled in 433, but Sixtus himself had come into conflict with Proclus, patriarch of Constantinople. He died on Aug. 18, 440, and is commemorated on March 28.

SIXTUS IV (Francesco della Rovere) (1414–1484), pope from 1471 to 1484, was born of a poor family near Savona on July 21, 1414. He entered the Franciscan order at an early age and studied philosophy and theology at the universities of Padua and Bologna. He was chosen general of his order in 1464. Three years later, in 1467, he was, to his own surprise, made cardinal-priest of S. Pietro in Vincoli by Paul II. He was elected pope in succession to Paul on Aug. 9, 1471. The fleet that he sent, under Cardinal Oliviero Carafa, against the Turks in 1472 participated in the landing at Smyrna, but a new expedition in the following year was a failure. His relations with France were strained because of the Pragmatic Sanction of 1438 and more so after Louis XI's ordinance of 1475 requiring that no papal decree be published in France without the royal placet. Sixtus likewise continued in 1474 and in 1476 his predecessor's negotiations with the grand duke Ivan III of Muscovy for the reunion of the Russian Church with the Roman see and for support against the Turks, but without result. He was visited in 1474 by King Christian of Denmark and Norway, and in the following year he established the University of Copenhagen.

Sixtus soon abandoned universal interests in order to concentrate attention on Italian politics and showed himself a confirmed nepotist. He was cognizant of the conspiracy of the Pazzi (1478), plotted by his nephew, Girolamo Riario, against Lorenzo de' Medici (*see* PAPACY: *The Renaissance Papacy*). He entered into a fruitless and inglorious war with Florence which kept Italy for two years (1478–80) in confusion. He next incited the Venetians to attack Ferrara (1482) and then, after having been delivered by their general Roberto Malatesta from a Neapolitan invasion, turned upon them and eventually laid them under an interdict (1483) for refusing to desist from the hostilities which he had himself instigated. He relied on the cooperation of Ludovico Sforza, who speedily forsook him, whereupon peace was forced upon him by the princes and cities of Italy. Sixtus died Aug. 12, 1484.

In 1475 Sixtus instituted the office of the Immaculate Conception for Dec. 8; in 1478 he formally annulled the decrees of the Council of Constance; by a brief of January 1482 he condemned abuses in the Spanish Inquisition; and in April 1482 he canonized St. Bonaventura. He granted many privileges to the mendicant orders, particularly to his own Franciscans. The most praiseworthy side of his pontificate was his munificence as a founder or restorer of useful institutions and as a patron of letters and art. He established and richly endowed the first foundling hospital, built and repaired numerous churches, constructed the Sistine Chapel (1473–81) and the Sistine Bridge, improved church music and instituted the Sistine Choir, commissioned paintings on the largest scale, pensioned men of learning (notably Bartolomeo Platina) and, above all, immortalized himself, from 1471, as the second founder of the Vatican Library. These great works, however, were not accomplished without grievous taxation. Annates were increased and simony flourished.

(X.)

SIXTUS V (Felice Peretti) (1520–1590), pope from 1585 to 1590, was born at Grottammare in the march of Ancona, near Montalto, on Dec. 13, 1520. Brought up in poverty, he entered a Franciscan monastery in 1533. He early showed rare ability as a preacher and dialectician. Sent to Rome in 1552, he attracted the attention of the future popes Paul IV (Carafa) and Pius V (Ghislieri). He was appointed inquisitor general in the Venetian republic in 1557 but became involved in disputes and had to leave (1560). Sent to Spain with the legation under Cardinal Buoncompagni (later Gregory XIII) in 1565, he conceived a strong dislike for Buoncompagni and hurried back to Rome on the accession of Pius V, who made him vicar apostolic of the Franciscans and bishop of Sant' Agata dei Goti in 1566 and cardinal on May 17 1570. Henceforth, as cardinal, Peretti was known by the name of Montalto. During the pontificate of Gregory XIII he lived in retirement, occupied with the care of his villa and with his studies (the first volume of his edition of the works of St. Ambrose appeared in 1580). Yet he did not neglect to follow the course of affairs, though carefully avoiding every occasion of offense. This discreetness contributed not a little to his election to the papacy on April 24, 1585.

The terrible condition in which Gregory XIII had left the states of the church called for prompt and stern measures. Against the prevailing lawlessness Sixtus proceeded with an almost ferocious severity, bringing thousands of brigands to justice by proceeding with vigour against their supporters among the powerful nobility. Within a short time the country was again quiet and safe, but Sixtus had made many enemies. He turned next to financial reform. By the sale of offices, by the creation of new *monti* (loans) and by levying new taxes, he accumulated a vast reserve, which he kept against certain specified emergencies, such as a crusade or

the defense of the Holy See. He moreover pursued an active economic policy by regulating food prices and by encouraging agriculture and the production of wool and silk. Immense sums were spent on public works and buildings, yet Sixtus ended his reign as one of the richest princes in Europe, having begun it with an almost empty treasury.

It is because of his achievements in reforming the central administration of the church that Sixtus must be reckoned as one of the greatest popes. By the bull *Postquam Verus* (Dec. 3, 1586) the college of cardinals was given its definitive form, its number being limited to 70. The secretariat of state was reorganized, and in January 1588 the entire administrative system of the curia was overhauled. The number of congregations was increased to 15, of which 6 dealt with secular administration and the other 9 with spiritual matters. It was through the machinery thus established that the decrees of the Council of Trent were effectively enforced. In particular, Sixtus insisted that the decrees regulating residence and investiture be strictly observed. So he must be counted as one of the founders of the Counter-Reformation.

His intervention in doctrinal affairs was not so happy. He had good grounds for supposing that the commission appointed to prepare a revised edition of the Vulgate, which had benefited enormously by his injection of a spirit of urgency into its deliberations, had not sufficiently considered the practical problems created by their work of scholarship. His reaction was typical: he rejected the work of the commission and took the whole task into his own hands. After 18 months of intense application, he produced the *editio Sixtina* in May 1590. But his revision was far too hurried and far too conservative, and the opportunity afforded by its numerous printer's errors was taken to postpone promulgation. Sixtus' death then intervened, and his edition was eventually abandoned. By the same event, Robert Bellarmine's book on doctrinal controversies was saved from official condemnation and the Society of Jesus from a drastic revision of its constitution.

In his political relations with foreign princes, Sixtus was faced by a dilemma. Distrusting Philip II of Spain, he viewed with misgiving the extension of Philip's power but was obliged to abet him as Henry III of France showed himself ever less able to hold his own between the pro-Spanish party of the Guises and the Huguenots under Henry of Navarre. Moreover, Elizabeth of England, whose personality Sixtus greatly admired, was an obstinate heretic. Thus he excommunicated Henry of Navarre (1585), promised subsidies for a Spanish invasion of England, and denounced Henry III after the coup against the Guises. In the last months of his life, however, he saw the hope that Henry of Navarre would make good his claim to the crown of France (as Henry IV) and be converted to Catholicism. Sixtus could then begin to withstand the demands of Philip's immediate ambition, confined as this was to France since the defeat of the Armada. Negotiating still both with Philip's and with Henry's envoys, he died on Aug. 27, 1590.

Posterity ranks Sixtus one of the greatest popes. He was hasty, obstinate, severe, autocratic; but his mind was open to large ideas, and he threw himself into his undertakings with an energy and determination that often compelled success. Few popes can boast of greater enterprise or larger achievements. *See* also PAPACY.

SJAELLAND (ZEALAND), the largest island of Denmark proper, with an area of 2,709 sq.mi. (7,016 sq.km.) and a population (1960) of 1,771,557. It is separated on the west from the island of Fyn (Fünen) by the Great Belt (Store Baelt) and on the east from southern Sweden (Skåne) by the busy Sound (Øresund). Extending 82 mi. (132 km.) from north to south and 68 mi. (109 km.) from west to east, the island has a basal platform of Cretaceous rocks whose raised eastern rim is exposed in the magnificent chalk and limestone cliffs at Stevns Klint. But solid geology is generally obscured by thick morainic deposits forming a gently undulating, lake-strewn landscape that attains its maximum height at Gyldenløves Høj (413 ft. [126 m.]). Coastal subsidence has produced sinuous inlets, such as Isefjord, and broad bays like Køge Bugt. Although the fertile clay loams support some of Denmark's best farmland, the urban character of the island is also pronounced. Besides Copenhagen and its suburbs, urban settlements range from the old cathedral city of Roskilde (*q.v.*) to the historic port of Elsinore (*q.v.*; Helsingør) and the ferry station of Korsør.

The island has eight major administrative units: the city of Copenhagen (*q.v.*); the adjoining borough of Frederiksberg; the four counties (*amter*) of Frederiksborg, Holbaek, Sorø, and Praestø (*qq.v.*); and the county council districts of Copenhagen and Roskilde. *See* also DENMARK. (HA. T.)

SKAGERRAK, a long, rectangular arm of the North Sea, trending southwest to northeast and separating the low-lying northern coast of the Danish peninsula of Jutland from the more mountainous fjord coast of southeastern Norway. Approximately 130 mi. long and more than 70 mi. (110 km.) wide, it is shallowest in the south off the smooth dune-fringed Danish shore, which leads to the great curving spit of the Skaw (Skagens Odde). Between the Skaw and the opposite shore of Sweden on the east the outlet of the Skagerrak narrows to 40 mi. (65 km.) before continuing southward into the Kattegat (*q.v.*) Strait and on to the Baltic Sea. The principal ports of this busy shipping lane are Oslo and Kristiansand (*qq.v.*), Nor., and Strömstad, Swed. (HA. T.)

SKAGWAY, a town of Alaska, U.S., situated at the north end of Lynn canal, a deep and narrow arm of the sea thrust far up between picturesque mountain ranges, is at the head of navigation in the waters of southeastern Alaska. Skagway owes its importance to being the seaward terminus of the White Pass and Yukon railway. This road, built in the years 1898–1900, extends up the valley of the Skagway River to the summit of White Pass, 20 mi., crossing there the international boundary and continuing thence down on the Canadian side 91 mi. to Whitehorse, head of navigation on the Yukon. Pop. (1960) 659.

Historically, it is of interest as the landing place of large quantities of supplies and many thousands of people during the Klondike gold rush of 1897–98 to reach the newly discovered deposits in the upper (Canadian) Yukon.

SKANDERBEG (GEORGE KASTRIOTI) (1405–1468), the national hero of the Albanians. He was the youngest son of John Kastrioti, head of one of the ruling families, whose possessions, extending over parts of central and northern Albania, included the famous fortress of Krujë. As John Kastrioti was defeated during the first incursions of the Ottoman Turks into Albania, he had to surrender Krujë and to give his four sons as hostages to the sultan. Thus George, a convert to Islam, was educated at the military school at Edirne (Adrianople). Sultan Murad II, impressed by his intelligence and by his ability at martial games, attached him to his personal staff. He gave him the name Iskander (Alexander), with the rank of bey—a style subsequently modified by his countrymen into Skanderbeg.

In 1443 Skanderbeg was serving on a military expedition against the Christians led by János Hunyadi (*q.v.*). During battle near Niš, in Serbia, he heard that the Albanians were rising against the Turks. Leaving the field, he hastened to Krujë, overpowered the Turkish garrison there, hoisted the Albanian flag, proclaimed himself a Christian, and declared a holy war. After reconquering the family possessions, he appealed to the Albanian leaders to unite against the foreign invader. They responded with enthusiasm, a national convention met at Lezhë (Alessio, then occupied by the Venetians), an Albanian league was formed, and Skanderbeg was appointed commander in chief.

Skanderbeg's struggle was to last for the rest of his life. Year after year Murad sent armies to subdue the rebellion; and while he fought successfully against the Turks, Skanderbeg had also to defend himself against the intrigues of the Venetians. In 1450 Murad himself, at the head of a powerful army, besieged Krujë for five months, till Skanderbeg's harassing tactics from the sur-

rounding mountains forced him to renounce the enterprise. This victory made Skanderbeg a hero throughout the Western world, but the devastation left behind by the invaders was appalling, and the Albanian league was weakened by desertions to the enemy or to the Venetians.

Going abroad in search of support, Skanderbeg concluded an alliance with King Alfonso I of Naples (Alfonso V of Aragon). Appointed captain general of the crown of Aragon, he was granted an annual pension of 1,500 ducats, while Catalan troops were sent to garrison Krujë. In 1451 Skanderbeg married Andronika, daughter of George Araniti (d. 1461), lord of Shpat and Kaninë and a member of the Albanian league.

An Albanian attempt to liberate Berat from the Turks was unsuccessful, but Skanderbeg destroyed another Turkish Army despatched against him. Pope Calixtus III named him "captain general of the Holy See." After an interval of service in Italy, on behalf of Alfonso's son Ferdinand against the Angevin rivals of the Aragonese, Skanderbeg returned to Albania to resist the continued attacks of the Turks. Sultan Mohammed II, having conquered Constantinople (1453), was eager to put an end to Christian resistance in the Balkans; but the armies which he sent every year from 1455 to 1462 were constantly defeated by Skanderbeg.

By clever diplomacy Skanderbeg obliged Venice to sign an alliance with him (1463): the Venetians sent 1,300 men to Albania for a new offensive against the Turks and granted a subsidy of 2,000 ducats. Pope Pius II's call for a crusade against the Turks fell on deaf ears, however; and when the pope died suddenly the Albanians were left to fight practically alone. For three years Balaban Pasha, an Albanian renegade in command of the Turkish Army, crossed swords with Skanderbeg. Then, in 1466 Mohammed II laid siege to Krujë in person, at the head of a strong army. Unable to take the fortress, the sultan retired, and the remaining Turkish forces were eventually decimated, Balaban Pasha himself being killed.

Skanderbeg, dressed as a simple soldier, went to Rome to seek help. At a ceremony in St. Peter's he received a sword and a blessed cap from Pope Paul II; and a subsidy of 7,000 ducats followed. Sultan Mohammed's second siege of Krujë (1467) was another disaster for the Turks, but it was Skanderbeg's last triumph. He died at Lezhë on Jan. 17, 1468, and was buried in the Cathedral of St. Nicholas, which had been rebuilt sometime earlier under his orders. His widow and his son were taken to Venice. The citadel of Krujë did not fall to the Turks till 1478.

See Athanase Gegaj, *L'Albanie et l'invasion turque au XV^e siècle* (1937); Fan S. Noli, *George Castrioti Scanderbeg* (1947). (T. Z.)

SKANDERBORG, an *amt* (county) of Denmark in east central Jutland, extending inland from Horsens Fjord. Area 664 sq.mi. (1,719 sq.km.); pop. (1960) 137,865. The fertile clay loams of the east support good mixed farming. The highest land in Jutland occurs in the hummocky moraine belt between Skanderborg and Silkeborg, the principal hills being Yding Skovhøj (568 ft. [173 m.]), Ejer Bavnehøj (561 ft.), and Himmelbjaerget (482 ft.). Broad, flat-floored valleys, like that of the Gudenaa (Denmark's longest stream), dissect the wooded upland and contain beautiful lakes, *e.g.*, Mossø. The principal towns are Horsens (pop. [1960] 37,261), Silkeborg (24,465), and Skanderborg (5,482). (Ha. T.)

SKARABORG, a *län* (county) in central Sweden between Lakes Vänern and Vättern, extending about 80 mi. (129 km.) both north-south and east-west. Pop. (1960) 250,180; area 3,262 sq.mi. (8,449 sq.km.). The county mainly drains toward Vänern and so for long has looked toward Göteborg and not to Stockholm. The higher land results from faulting and local preservation of resistant rocks; the highest summits are Mosseberg (1,072 ft. [327 m.]) and Kinnekulle (1,007 ft. [307 m.]). Limestone outcrops are extensively quarried; near Skövde are important cement works. Glacial deposits usually occur as infertile sands and gravels, but remnants of deposits from the Yoldia Sea transgression have given fertile areas. Falköping is an ancient city, and much Swedish culture and law derives from this region. Agriculture dominates the district although match making and automobile assembling are done at Tidaholm. Mariestad, on the east shore of Vänern, is the county town and a rail junction, with a 17th-century church and castle. Skara, 25 mi. (40 km.) SW of Mariestad, has a 12th-century cathedral. It became a bishopric in the 11th century and had the first Swedish high school (1641). (A. C. O'D.)

SKARA BRAE, the most perfect Stone Age village in Europe, was embalmed under a sand dune on the shore of the Bay of Skaill on the Atlantic coast of Mainland Island, largest of the Orkneys, Scot. Exposed by a great storm in 1851, four buildings were excavated during the 1860s by William Watt, laird of Skaill. After another storm in 1926 further excavations were conducted by the ancient monuments branch of the ministry of works, that had assumed guardianship of the monument, supervised from 1928 to 1931 by V. G. Childe, of the University of Edinburgh. Before 1939 the age of the site and the cultural status of its builders remained uncertain, but in that year excavation by Walter G. Grant at a contemporary village, Rinyo, on Rousay, established that the dwellings of Skara Brae were built before the first people to use bronze in Great Britain, the Beaker Folk, reached Orkney, and so belonged to the New Stone Age of Orkney. In the 1960s archaeologists estimated that Skara Brae had been built *c.* 2000–1500 B.C.

Though the dwellings at Skara Brae are built of undressed slabs of stone from the beach, put together without any mortar, the drift sand that filled them immediately after their evacuation preserved the walls in places to a height of 8 ft. (but unfortunately not the roofs). Moreover, because of the absence of trees on the island, articles of furniture that would normally be carved in perishable wood had to be made of stone and have, therefore, survived. At the same time the dwelling explored in 1928 was found exactly as it had been left by its occupants who had been forced to abandon it in precipitate haste by a violent storm. The village consisted of several one-roomed dwellings, each constructed on the same plan. Each is a rectangle with rounded corners, the largest measuring 21 ft. by 20 ft. square. Entering through a narrow doorway only 4 ft. high that could be closed by a stone slab held in place by a sliding bar, the visitor finds in the centre of the room a rectangular fireplace still filled with peat ash. Behind it against the rear wall stands an erection of two tiers of stone shelves precisely like a modern dresser. On either side of the central hearth are enclosures of stone slabs exactly similar to the fixed beds of planks built in the 19th century in Norwegian peasant houses, that on the right being always the larger. Tall uprights of stone at the corners like bed posts served to support some sort of canopy. In the wall above the bed are recesses that must have served as keeping places for personal possessions. Sunk in the floor are several cubical boxes lined with stone slabs and luted with clay along the joints, evidently designed to hold some sort of liquid. One or more small cells in the thickness of the walls

J. ALLAN CASH

EXCAVATED DWELLING AT SKARA BRAE

open off the main room. Beneath its floor a slab-lined drain runs to debouch into a main sewer.

At the moment of its abrupt desertion the village had consisted of seven or eight such huts linked together by paved alleys. By this time six huts had been put artificially underground by banking around them midden consisting of sand and peat ash stiffened with dung and other refuse, and the alleys had become tunnels through this midden roofed with slabs. On the west (the east end has been destroyed by the sea) the main tunnel gave through a doorway, identical in design with those of individual dwellings, onto an open space paved with slabs, but unroofed. A hut, entered from this space and standing free of the general midden-heap cover, differed to some extent in arrangement and furniture from the rest; it contained a kiln where the dresser should have stood and had been used for the manufacture of chert implements. The whole residential complex was drained by a built sewer into which the drains from individual huts discharged.

The inhabitants of the village lived mainly on the flesh and presumably the milk of their herds of tame cattle and sheep, on limpets and other shell fish, supplemented exceptionally by red deer, wild boar, seal and whale. There is no positive evidence that they cultivated any cereals or that they spun and wove wool or other material. Presumably they dressed in skins. Bone tools suitable for preparing and piercing such skins were very numerous, while large pins made of narwhal ivory, whalebone or the penis-bones of seals could be used for fastening them. Peat was regularly burned as fuel, while fire may have been made by striking nodular hematite against flint or chert. For their equipment the villagers relied exclusively on local materials. Axheads, or rather adz blades, were made of stone sharpened by grinding and were sometimes attached to their handles with the aid of perforated sleeves of stag's antler. Knives were made by splitting beach pebbles along their bedding planes. The bones of cattle and sheep served for the manufacture of awls, needles, fabricators and various tools of uncertain use probably employed in dressing hides. Vessels were made of pottery. Though the clay was exceedingly coarse and included large grits, and the firing was not sufficient to convert it into pottery right through, most vessels were quite richly decorated with elaborate patterns in relief formed by applying to the surface strips and pellets of clay. Vessels were also made out of the vertebrae of whales and blocks of sandstone.

No weapons at all were found at Skara Brae unless some unique objects carved out of hard volcanic stone were so used. These include balls covered with pyramidal spikes and other spikey forms, all carved with great accuracy. As ornaments the villagers wore pendants and beads made out of the marrow bones of sheep, the roots of cows' teeth (the nerve canal serving as a string hole), the teeth of killer whales and boars' tusks.

Nearly 1,000 finished beads were found together in one cell, and unfinished beads in all stages of manufacture lay about the hut floors. Red, yellow and white pigments contained in little paint pots of stone or cetacean bone were presumably used in painting the person. Games were played with dice of walrus ivory and with knucklebones.

The skeletons of two old women, buried together doubled up, were found in a cist under the wall of the hut discovered in 1928 and have been interpreted as a foundation sacrifice. Watt had previously discovered a skeleton in a niche beside the main alley, but the village cemetery has not been identified. The two old women must have stood about 5 ft. 2 in. in height, not much, if anything, below the average of the female stature prevailing in the mid-20th century. Both had suffered from osteoarthritis. The leg bones show peculiarities due to habitual squatting. The skulls are just dolichocranial (index 74.5).

A number of stones in the walls of the huts and alleys have been roughly scratched with lozenges and similar rectilinear patterns.

Beneath the walls of the huts just described the foundations of older huts were discovered in 1930. In plan and furniture these agreed precisely with the former and the relics on their floors were of the same kind as those described above. The pottery from the lower levels was adorned with incised as well as relief designs. Among these was the true spiral represented on one sherd —the only example of this pattern in pottery known in prehistoric Britain.

SKARZYSKO KAMIENNA, an industrial town of Poland in Kielce *wojewodztwo* (province). Pop. (1960) 35,000. It is situated in the Little Polish Highlands, in the wide valley of the Kamienna River, a tributary of the Vistula, and is surrounded by extensive woods. The development of the town has been associated with the iron industry established there in the 19th century, using local ores from the Old Polish Basin. The old plants of Kamienna were closed in 1878 as unprofitable, but new and continued development started in 1881, after the building of blast furnaces. The town is now an important centre of the metal and mineral industries and is a railway junction on the Warsaw–Cracow line. (T. K. W.)

SKAT, a game of cards, much played in Germany and by people of German origin throughout the world. It is an elaboration of *Schafkopf* (sheepshead), a Wendish game believed to date at least to the middle 1700s. In 1811 a resident of Altenburg who had newly learned *Schafkopf* carried it into the local tarok club, where it was modified by the addition of features from tarok and kalabrias. The very name of the game is a tarok term, derived from the Italian *scartare*, "to discard," or *scatola*, a "place of safe-keeping." In the earliest writings, the game is spelled "scat." Much of the early development of skat is credited to F. F. Hempel, an advocate in Altenburg. The first book on it was published by his cousin, J. F. L. Hempel, in 1848. After a long period of experimentation, the game was codified by a congress of more than 1,000 skat players, convened at Altenburg on Aug. 7, 1886. Subsequent modifications chiefly concerned the use of the skat (widow) and elimination of the game *frage*.

Skat is very popular in some sections of the United States and large tournaments are played for prizes. Laws of the game are promulgated by the North American Skat league and do not in all respects conform to the procedure of play in Germany.

Skat is played by three players with a pack of 32 cards. Each receives ten cards and two are dealt face down for a skat (widow). The players bid by numbers, in multiples of two, and the high bidder then names his game. In the game tournee the trump suit is fixed by a card turned from the skat—it may be a grand (in which only knaves are trumps) if a knave is turned. Solo is played without help of the skat, and the player may name a suit or grand. Gucki is a grand using the skat. Null is a bid to take no tricks, at no trumps. Ramsch is played only if all three players pass, the object being to win fewest points in tricks, with knaves trumps.

The bidding and scoring values of the games are determined by their base values times the sum of all due multipliers. The multipliers arise from various sources—points won in play, prediction or announcement as to this outcome, and matadors, which are top trumps in unbroken sequence.

To make his bid, the player must take a majority of the 120 card points: each ace 11, ten 10, king 4, queen 3, knave 2. Except in ramsch, the other two players combine in temporary partnership to try to defeat him.

A modern variant, *Räuber Skat*, popular in club play but not in tournaments, eliminates the game tournee. Instead, the high bidder always has the option of taking the skat or of playing without it. In the latter case, handplay, he earns an extra multiplier.

See Walter J. Zarse, *Sheepshead and Skat* (1935); "The Official Rules of the North American Skat League," in *The Official Rules of Card Games* (1946). (G. Mh.)

SKEET SHOOTING: *see* Trapshooting and Skeet Shooting.

SKEGNESS, an urban district and seaside resort in Lincolnshire, Eng., lies 42 mi. E of Lincoln by road. Pop. (1961) 12,847. Since 1873 the fine sand dunes, beach, and bracing air have drawn tourists in large numbers from the Midlands and farther afield.

There are a pier and picturesque gardens and waterways along the front. The adjoining Seacroft and North Shore golf courses attract national competitions, and the Skegness and Gibraltar Point Nature Reserve, with its bird observatory and field research station, is now a centre for natural history research with a full-time warden and residential accommodation for students. The wold village of Somersby, birthplace of Alfred, Lord Tennyson, is about 12 mi. NW. (F. T. BA.)

SKELETON, INVERTEBRATE. The function of the skeleton is to provide a more or less rigid framework upon which the muscles can react. In many invertebrate animals no such framework exists; the necessary rigidity is provided by the hydrostatic pressure of the body fluids acting upon a soft and pliable skin. This is seen in caterpillars and, to a lesser extent, in soft worms and in mollusks, where the necessary pressure is maintained by the steady contraction of an interlacing sheet of superficial muscles, the so-called turgor muscles. The muscles that move the body are attached to the skin, which is made rigid by this internal pressure. The firmness of some invertebrate animals is maintained by a mechanism similar to that in many plants; the individual cells that form the body wall are more or less distended by water to give some degree of rigidity. But in many invertebrates, rigid skeletal materials are deposited either on the outer surface of the body or within the cells. In some animals these rigid structures do not afford attachment for the muscles but merely provide a protective armour.

It is usual to classify skeletal structures as external (exoskeleton) or internal (endoskeleton). But the one type merges with the other, even within the same animal; and in many examples of what appears to be an exoskeleton, the hard material is laid down inside the cells that form the outer covering.

The invertebrate skeleton is exceedingly varied in composition and extent. These variations cut across the ordinary classification of animals. In the Protozoa, for example, there are all grades between soft forms (*e.g., Amoeba*) and forms with a cuticle, which may be proteinaceous (in *Monocystis*) or composed of cellulose (in the plantlike flagellates). Other protozoa have definite shells, composed of protein with various foreign bodies incorporated in it, siliceous plates, lime (in most Foraminifera) or cellulose (in the resting stages of slime molds). The Radiolaria have an internal lattice of silica laid down inside the cell, a kind of endoskeleton.

Other groups show a similar variation. Some sponges deposit needlelike spicules of calcium carbonate in the jelly (mesogloea) beneath the outer epithelium; others produce spicules of silica held together by a horny substance termed spongin; and yet others have a skeleton of spongin alone and no spicules. Similarly, among coelenterates, there are Hydrozoa that have a horny covering protecting the polyps, and others with an external calcareous skeleton. Anthozoa show the same diversity. In *Alcyonium* (dead men's fingers) the skeleton is mainly internal, consisting of spicules of calcium carbonate in the mesogloea. In the red coral of commerce (*Corallium*) the spicule-bearing cells migrate inward and build up a central skeleton. In the common reef-building corals the calcareous skeleton is secreted by that part of the ectoderm that forms the basal disc. This secretory process is continuous and the polyp raises itself progressively upon a growing stem of lime.

In the echinoderms the calcareous deposits are laid down in the mesoderm. They may be so scattered that they merely serve to impart a leathery consistency to the skin (as in holothurians); or they may form well-articulated ossicles united by muscles and thus serve as a typical internal skeleton (as in the arms of brittle stars); or they may be set closely together to form a rigid armour (as in the sea urchins). Many sea urchins have projecting spines on which the epidermis has been worn away so that the calcareous substance is exposed.

The shell of mollusks is an example of an external skeleton. It is secreted by the ectodermal epithelium of the mantle, and consists of an outer layer of the horny substance conchiolin, an intermediate prismatic layer composed of calcite, and a smooth inner layer (the nacreous layer), also composed mainly of calcium carbonate. The first two layers are secreted by a marginal band of cells, so that the shell grows at its outer margin. The nacreous layer is secreted by the general surface of the mantle and is the material of which pearls are formed around foreign bodies introduced into the mantle cavity.

The exoskeleton attains its most elaborate forms in the arthropods (crustaceans, insects, etc.). Many soft invertebrates, such as worms and mollusks, secrete a protective layer of slime or mucus over the surface of the integument. In the arthropods a solid substance termed chitin forms the basis of the exoskeleton. Chitin is related chemically to mucus. It consists of a nitrogen-containing carbohydrate (a polysaccharide, polyacetyl glucosamine) intimately associated with protein. If the protein component is removed from natural chitin, there remains a material, often called pure chitin, the physical properties of which are very similar to those of the cellulose of plants.

Natural chitin forms a cuticle that is tough but flexible. It exists in this state in the integument of caterpillars, which, as noted above, have a hydraulic type of skeleton dependent on internal turgor. It exists in this soft state also in the joints of the limbs or between one segment of the body and the next. But in most arthropods the segments of the body or of the limbs are in the form of rigid plates that form a true exoskeleton linked to adjacent segments by flexible membranes. The hard material responsible for this change in the chitin is termed sclerotin, and the hardening process is called sclerotization.

The chemical nature of sclerotization is not fully understood, but it is certainly closely related to the hardening of proteins by tanning. Substances capable of causing tanning (notably certain quinones) are almost certainly produced in the cuticle of arthropods during the hardening process. The resulting product (sclerotin) is a kind of natural plastic. In its horny consistency it closely resembles keratin; both are cross-linked or polymerized proteins, but the chemical nature of the linkage is different in the two substances. It is probable that other skeletal proteins in invertebrates, such as the spongin of sponges and the conchiolin of mollusks, are also tanned proteins allied to sclerotin.

In many crustaceans (crabs, lobsters, etc.), much of the cuticle is rendered hard by the incorporation of lime in the form of aragonite or calcite. But sclerotin is actually harder than calcite, and those parts of crustaceans that need to be of maximum hardness, such as the mandibles and the tips of the claws, are in fact composed of sclerotin. The hardest parts of insects are often the darkest; the hardening and darkening processes are closely associated chemically.

Besides functioning as a skeleton, the cuticle of terrestrial arthropods must act as a waterproof covering in order to prevent these small animals from drying up. This waterproofing is effected by the secretion of a layer of crystalline wax on the surface layer of the cuticle. Such a wax layer, if freely exposed, would be excessively fragile. It is commonly protected by a thin layer of cement substance poured over its surface by small dermal glands. Other glands may discharge quantities of wax, lac and other products upon the surface of the insect.

The cuticle of arthropods is the product of a single layer of epidermal cells; indeed cytoplasmic processes from these cells (so-called pore canals) penetrate far into the cuticle, so that it is really a living structure. It can undergo endless modifications of form to produce sensory hairs, pigment-bearing scales, claws, wings and other kinds of tools. In some insects it shows brilliant metallic colours that result from the presence of some fine structure in the cuticle (multiple thin plates or ridges) that gives rise to interference. In order that the arthropod may grow, the old cuticle is shed from time to time, after a new and larger cuticle has been laid down beneath it. This process is termed molting or ecdysis. Until the new cuticle hardens, the arthropod is in a very vulnerable condition.

SKELETON, VERTEBRATE. In many animals and in all vertebrates, the general form of the body is maintained by means of certain elements that are hardened to form a structural framework called the skeleton. This persists after death for a variable length of time after the rest of the body has disintegrated. In higher vertebrates, the skeleton is rendered more rigid and permanent by the formation of bone. In many animals the shape and relative positions of the various parts of the skeleton determine the general body form.

In most invertebrates, the skeleton is on the surface to form a protection as well as a supporting framework, and is called an exoskeleton (*see* SKELETON, INVERTEBRATE). In the vertebrates there is an internal skeleton, called an endoskeleton; the exoskeleton is either greatly modified or completely suppressed. In the following account the human skeleton, consisting of 206 distinct bones plus a few others called sesamoid bones, is taken as an example of the mammalian skeleton; the bones of the head are discussed separately in the article SKULL. For the relationship of the skeleton to other anatomical structures *see* ANATOMY, GROSS (plates). This article is divided into the following sections:

I. VERTEBRAL COLUMN

The vertebral column (also known as the backbone, spine, or spinal column) consists of a series of vertebrae connected by thick elastic intervertebral discs and other ligaments (*see* fig. 1). The column lies in the middle of the back of the neck and trunk and is surmounted by the cranium; the column and cranium together comprise the axial skeleton. Each vertebra, with certain exceptions, consists of a thick anterior part, the body, and a posterior part, the neural arch (*see* fig. 2).

The paired nerves connected with the spinal cord (*q.v.*) emerge on each side of the vertebral column between successive vertebral bodies and neural arches. The bodies, with the intervertebral discs, form the weight-bearing portion of the vertebral column. The neural arches form partial protection for the spinal cord and for the proximal parts of the lower spinal nerves. Each neural arch consists primarily of two cylindrical pedicles, projecting backward from the body, and two flattened laminae, which meet in the midline posteriorly. At the junction of each pedicle and lamina, there is a laterally directed transverse process, and vertically disposed superior and inferior articular processes (pre- and postzygapophyses). The superior articular processes of one neural arch articulate with the inferior articular processes of the arch above at a synovial joint. A spinous process projects backward from the fused laminae and can be felt under the skin.

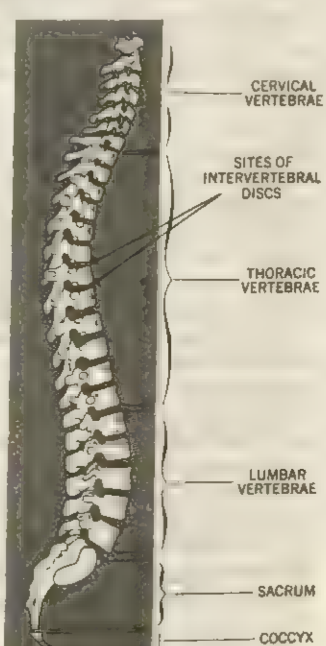

FIG. 1.—RIGHT SIDE VIEW OF THE ADULT VERTEBRAL COLUMN

In the young child, the vertebral column consists of 33 separate vertebrae. In the adult, some of these are fused together, so that there are only 26 separate bones. The vertebrae are grouped from above downward according to position into cervical, thoracic, lumbar, sacral, and coccygeal. For the human infant, the number of vertebrae in each group is expressed in the formula C_7, Th_{12}, L_5, S_5, Coc_4, but in the adult the five sacral vertebrae have fused to form a single triangular bone, the sacrum, and the four coccygeal to form the coccyx.

Vertebrae.—The cervical vertebrae are distinguished by the presence of a foramen (hole) in the transverse process. These foramina, excepting that of the 7th vertebra, are in succession traversed by the vertebral artery carrying the blood to part of the brain. The 1st cervical vertebra, or atlas, is atypical in that it has no body but is in the form of a ring. On each side of it there is a thick mass of bone by which it articulates above with the occipital bone of the skull and below with the 2nd vertebra, the axis. The body of the latter is surmounted by a stout, peglike odontoid process, which is regarded as the body of the atlas. This process forms a pivot round which the atlas moves, with the skull, when the head is turned from side to side.

Each of the typical thoracic vertebrae (1st to 9th) is distinguished by the presence, on each side of its body, of a small, smooth facet for articulation with the head of a rib. In addition, these vertebrae have a facet on each transverse process for articulation with the tubercle of a rib. The body of the 10th thoracic vertebra, however, articulates only with one rib. In the case of the 11th and 12th vertebrae, there are articular facets on the body but not on the transverse processes.

The lumbar vertebrae have neither foramina in the transverse processes nor articular facets on the bodies. The bodies are massive in order to transmit the weight of the trunk.

The sacrum is a large triangular bone formed by the fusion of five vertebrae; with the two hipbones, it forms the pelvic girdle. The anterior surface of the sacrum is concave and is marked by four transverse lines which indicate the sites of fusion of the original five sacral elements (*see* fig. 5). On each side of the fused bodies there are foramina (holes) for transmission of the anterior divisions of the upper four sacral nerves. The convex posterior surface shows four rudimentary spinous processes, and on each side of these are two rows of tubercles representing the articular processes and the transverse processes. Between the rows of tubercles four pairs of foramina transmit the posterior divisions of the sacral nerves. The part of the sacrum lateral to the foramina is known as the lateral mass. The upper lateral aspect of this mass presents an L-shaped articular surface for articulation with the corresponding hipbone. Posterior to the articular surface, the lateral mass is rough, for the ligaments that attach the sacrum to the hipbone. The human sacrum is broader in proportion to its length than that of other mammals, so that great solidity is given to the lower part of the spine; this breadth is probably correlated with the firmness of the sacrum's articulation with the hipbones, as an adaptation of the spine to man's erect posture. The sacrum is broader in women than in men and hence the whole pelvis is wider.

The coccyx consists of four rudimentary vertebral bodies fused together and, in the adult, commonly joined to the sacrum. The first body has a pair of small projections which are the vestiges of the neural arch.

Articulated Vertebral Column.—The vertebrae are held firmly together by a number of strong ligaments. The main ligaments are the intervertebral discs, the anterior and posterior longitudinal ligaments between the bodies, and the ligamentum flavum between the laminae. The intervertebral discs form flexible connections between the bodies of adjacent vertebrae from the axis above to the sacrum below. Each disc consists of fibrocartilage which encloses a central mass, the nucleus pulposus. The fibrocartilage is firmly attached to the adjacent vertebrae, whereas the nucleus pulposus is a semifluid structure acting as a shock absorber and can be deformed by pressure. Occasionally, the pressure developed in the nucleus pulposus is so great that the surrounding fibrocartilage ruptures and the nucleus protrudes ("slipped disc"; for this and other spinal ailments *see* SPINE, DISEASES AND DISABILITIES OF).

The articulated vertebral column forms the central axis of the skeleton and supports the weight not only of the head and trunk but also of the upper limbs. It gives attachment to the muscles

that move the column itself and to other muscles that move the head and limbs.

The vertebral column of an adult in the ordinary standing position exhibits curves in the sagittal (anteroposterior) plane of the body (*see* fig. 1), and minor curves in the coronal (transverse) plane. In the infant at birth, there are two primary sagittal curves concave forward which meet at the sacrovertebral junction. The lower curve involves the sacral and coccygeal vertebrae, the upper affecting the remainder of the column. When the infant begins to lift up its head, a secondary sagittal curve, convex forward, develops in the neck region, and when the child begins to walk, a further secondary sagittal curve convex forward is developed in the lumbar region. In the adult spine, therefore, there is a series of alternating convex and concave curves formed in adaptation to the erect posture of man. As a result of these curves the weight of the body is transmitted to the sacrum with the least expenditure of muscular effort. The curves in the coronal plane are not constant; the frequent convexity to the right has been attributed to the greater use of the right arm.

Movements of the vertebral column are: (1) forward bending, known as flexion, and the opposite movement, extension; (2) lateral bending, known as lateral flexion; and (3) rotation, which occurs about an axis passing vertically through the bodies of the vertebrae concerned. The range and kind of movements show great variations in the different parts of the column. They are greatest in the cervical region, at the thoracolumbar junction and at the lumbosacral junction. The limits of movement are determined by the planes of the joints between the articular processes, by the flexibility of the intervertebral discs, and by the extensibility of the muscles and ligaments. In the thoracic region movements of the vertebral column are more restricted because the ribs and costal cartilages resist distortion.

II. THORACIC SKELETON

The thoracic skeleton consists of the thoracic part of the vertebral column, the ribs with their costal cartilages, and the sternum. The bodies of the vertebrae project into the thoracic cavity from behind so that there is a recess of the cavity on each side of them.

The sternum, or breastbone, consists of three parts: an upper, the manubrium; a middle, the body; and a lower, the xiphoid process (*see* fig. 3). The anterior and posterior surfaces of the body are marked by transverse lines, indicating its division into four originally distinct segments. Each lateral margin of the sternum presents seven notches for articulation with the seven upper costal cartilages; at each side of the upper margin of the manubrium is a depression where the clavicle articulates; the xiphoid process remains cartilaginous up to a late period in life.

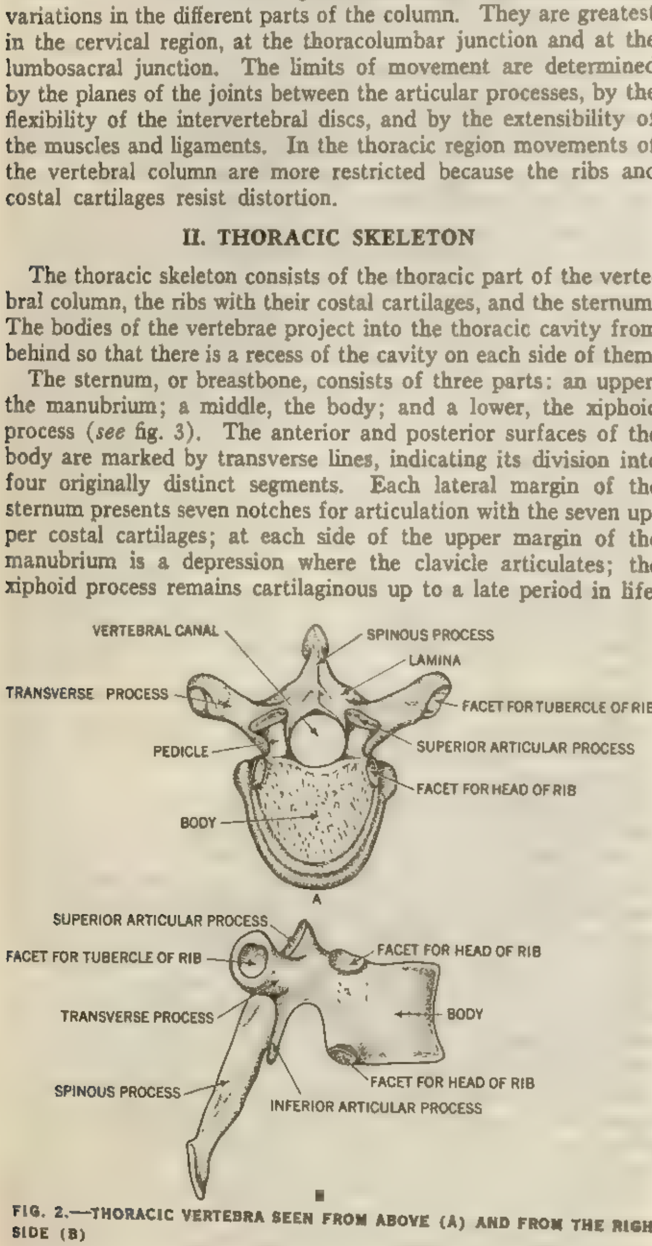

FIG. 2.—THORACIC VERTEBRA SEEN FROM ABOVE (A) AND FROM THE RIGHT SIDE (B)

Most skeletons have 12 pairs of ribs, which articulate behind with the thoracic region of the vertebral column. Occasionally cervical or lumbar ribs are present. From the vertebral column the ribs are directed first backward, then downward and forward to end at a lower level by joining the costal cartilages. The upper seven ribs are attached to the sternum by their costal cartilages and are called true ribs. The lower five ribs are called false ribs. The cartilages of the 8th, 9th, and 10th ribs do not reach the sternum directly but join the cartilages of the ribs immediately above. The cartilages of the 11th and 12th ribs have no anterior attachments, and these ribs are known as floating ribs.

A typical rib (from 3rd to 9th) consists of head, neck, and shaft. The head articulates with two adjacent vertebral bodies. A short neck separates the head from a tubercle, articulating with a transverse process. Beyond that the shaft curves round the side of the thorax to the costal cartilage.

III. APPENDICULAR SKELETON

The upper and lower limbs in man resemble one another in their general plan, but differ greatly in their detailed structure and in their mode of attachment to the trunk. Their functions also have undergone pronounced modifications; the upper limbs have been freed from supporting the body weight and have become grasping organs, whereas the lower limbs have to be used not only to propel the body but also to act as struts to prevent it from falling forward during locomotion. Each limb is attached to the axial skeleton by means of a bony girdle; that of the upper limb is called the shoulder (pectoral) girdle, and that of the lower limb the pelvic girdle. The shoulder girdle, consisting of the clavicle and scapula (*see* fig. 3, 4), has considerable mobility on the trunk; its sole skeletal connection with the trunk is through the articulation of the clavicle with the upper end of the sternum at the sternoclavicular joint. There is a wide range of free movement of the upper limb on the shoulder girdle, and this is supplemented by movements of the girdle on the trunk. The movements at the shoulder joint can take place about an infinite number of axes. Specific names are given for these movements, such as flexion, extension, abduction, adduction, rotation, and circumduction.

The lower limb articulates with the hipbone. This is firmly connected with the sacrum to form the pelvic girdle (*see* fig. 3, 4), which acts as a single skeletal unit in all ordinary body movements. It is through the hipbone that the weight of the trunk is transferred from the sacrum to the head of the femur. Conversely, the pelvic girdle transmits to the trunk the forces arising from action of the lower limb. Movements at the hip joint, like those at the shoulder joint, take place about a number of axes; the movements, however, are more limited. Certain of them are distinguished by names. Forward movement of the thigh relative to the pelvic region is called flexion, the backward movement extension. Movement of the limb toward the midline of the trunk is called adduction, the movement away from it abduction. Medial and lateral rotation of the limb can also occur, and the combination of all the movements is called circumduction.

Each of the limbs consists of three segments: proximal, intermediate, and distal.

The proximal segment in both arm and leg contains one long bone, the humerus in the arm and the femur in the leg.

The intermediate segment consists of two bones, the radius and ulna in the forearm and the tibia and fibula in the leg (*see* fig 5). The articulation of the intermediate with the proximal segment in each limb is hingelike; the joint is termed the elbow in the upper limb and the knee in the lower limb. Axial rotation (rotary movement) is fairly extensive at the knee except when the leg is completely straightened (extended) but is negligible at the elbow. The movements possible in the intermediate parts of the two limbs differ considerably; rotation, known as pronation and supination, can take place within the forearm by a movement between the radius and the ulna, but in the lower limb no comparable movement is possible.

The distal segments of the upper and lower limbs consist respectively of the hand and foot. These comprise: (1) a series of small bones, collectively called the carpus in the hand and the tarsus

in the foot; (2) five elongated bones, metacarpals or metatarsals, each of which supports (3) a finger or toe, known generally as a digit. Most of the digits consist of three bones called phalanges; the thumb and great toe are exceptional in having only two.

The articulation of the carpus with the radius and ulna, known as the wrist, allows movements around a transverse axis (*i.e.*, movements producing flexion and extension of the hand) and around an anteroposterior axis permitting abduction and adduction of the hand. Movements at the articulation of the tarsus with the tibia and fibula, known as the ankle, are almost restricted to a hingelike flexion and extension. In the foot there is a considerable range of movement between certain of the tarsal bones. The movement that turns the sole of the foot to face inward is known as inversion, while the movement by which it can be turned outward is known as eversion. These movements permit the sole of the foot to adapt itself to the surface contour on which it rests.

There is a general resemblance between toe and finger movements, but the joint at the base of the thumb between the first metacarpal and the adjacent carpal bone (trapezium) permits a variety of movements which is lacking in the big toe. At the metacarpophalangeal, metatarsophalangeal, and interphalangeal joints, hingelike flexion and extension movements take place. The movements are freer in the hand than in the foot.

A. Upper Limb

The bones of the upper limb are the clavicle and scapula of the shoulder region, the humerus of the upper arm, the radius and ulna of the forearm, and the numerous small bones of the hand (*see* fig. 3, 4).

Clavicle.—The clavicle, or collarbone, is an elongated bone which extends horizontally from the upper end of the sternum outward, to articulate with the acromion, the outermost process of the scapula (point of the shoulder). It presents a strong sigmoidal

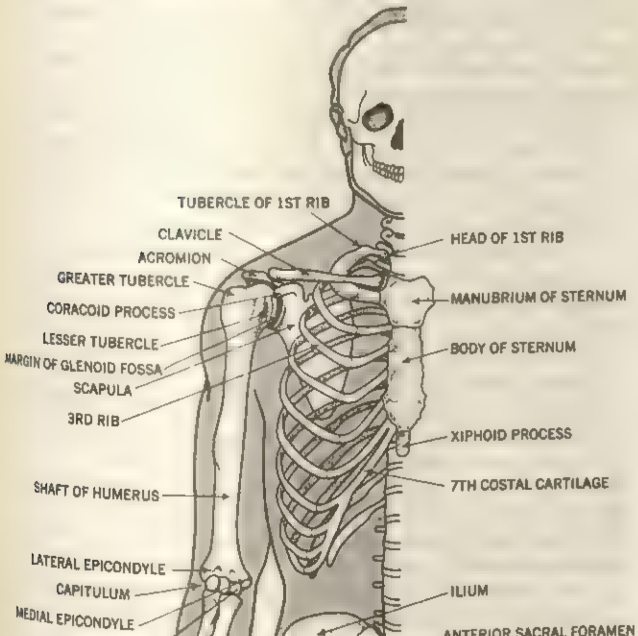

FIG. 3.—FRONT VIEW SHOWING RIGHT HALF OF SKELETON OF THE TRUNK AND UPPER LIMB

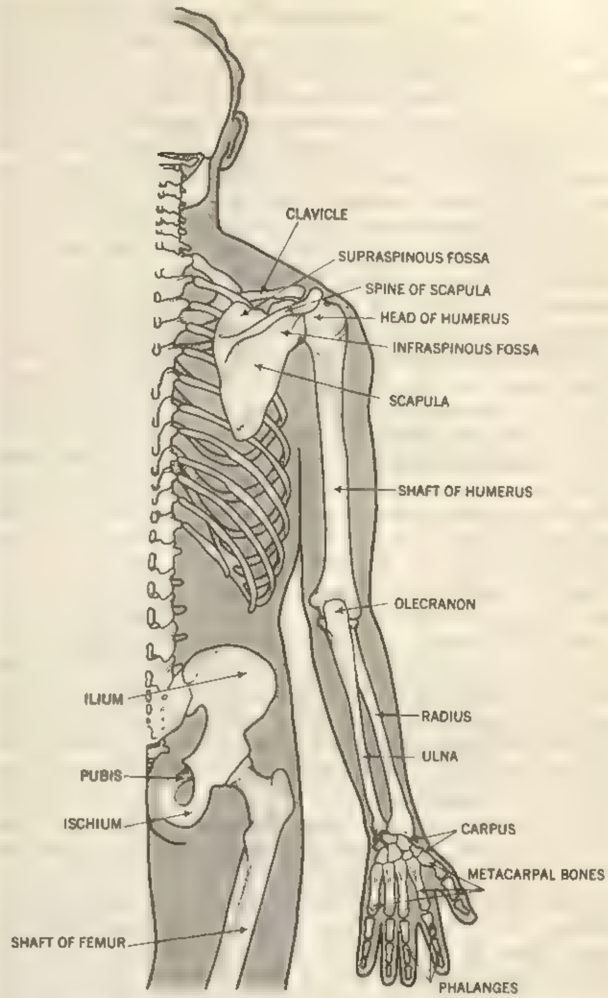

FIG. 4.—REAR VIEW SHOWING RIGHT HALF OF SKELETON OF THE TRUNK AND UPPER LIMB

curve, and is slender in the female but robust in muscular males. Its sternal end is thick; its acromial end, flattened from above downward, has an articular surface that meets a corresponding surface on the acromion. Strong ligaments connect the ends of the clavicle with the sternum and 1st rib and with the acromion and coracoid process of the scapula. The shaft gives attachment to muscles of the shoulder girdle.

Scapula.—The scapula, or shoulder blade, lies upon the upper part of the back of the chest, between the levels of the 2nd and 8th ribs. It is triangular in outline. Its anterior surface, which is concave, faces the ribs. Its posterior surface is crossed obliquely by a prominent ridge, the spine, which subdivides this aspect of the bone into a supraspinous and an infraspinous fossa (concavity). The spine and these two fossae give attachment to muscles which act in rotating the arm. The spine arches forward to end in the broad flat acromion by which the scapula articulates with the clavicle. To the margins of the scapula are attached muscles which participate in moving or fixing the shoulder as demanded by the movements of the upper limb. Of the three angles of the scapula, the outer is thickened and presents the shallow glenoid fossa, which articulates with the head of the humerus to form the shoulder joint. Overhanging the glenoid fossa is a beaklike projection, the coracoid process.

Humerus.—The humerus is a typical long bone, and as such presents a shaft and two expanded ends. The upper end possesses a hemispherical head with a smooth surface which articulates with the glenoid fossa of the scapula; where head and shaft merge, two tubercles are found, to which are attached rotator muscles which arise from the scapular fossae. Between the tubercles is a groove which carries the long tendon of the biceps muscle. The shaft of the humerus is three-sided in section above, but flattened and ex-

panded below. A broad, shallow groove winds round the back of the bone, lodging the radial nerve. The lower end of the bone consists of articular and nonarticular regions. The lateral articular region, the capitulum, articulates with the head of the radius, and the medial, the trochlea, articulates with the ulna. The nonarticular regions have projections, the medial and lateral epicondyles; each is surmounted by a supracondylar ridge. The medial epicondyle and ridge give attachment to the muscles that pronate the forearm and flex it and the fingers; the lateral epicondyle gives origin to muscles which participate in supination and in extension of the wrist and fingers.

Radius.—The radius, the lateral bone of the forearm, conforms to the type of a long bone. The upper extremity, or head, which is disc-shaped, articulates above with the humerus; the margin of the disc articulates with the ulna and with the annular ligament. The head of the bone is joined to the shaft by a neck, below which is a tuberosity into which the biceps muscle is inserted. The shaft of the radius affords attachment for muscles which act upon the fingers and the wrist. Its sharp inner margin gives attachment to the interosseous membrane, which forms a partition between the structures of the front and back of the forearm, affording surfaces for muscle attachments. The lower, or distal, end of the radius is much broader than the proximal end, and is marked posteriorly by grooves that lodge the muscle tendons passing to the back of the hand. From its outer margin a pointed styloid process projects downward. The inner margin of the distal extremity has a smooth concave surface for articulation with the lower end or head of the ulna, and its broad concave lower surface articulates with the scaphoid and lunate bones of the wrist.

Ulna.—The ulna is the long bone on the medial side of the forearm. Its proximal end is subdivided into two strong processes by the trochlear notch, the smooth surface of which articulates with the humerus. The lower, or coronoid, process is rough, receiving the insertion of the chief flexor of the forearm, the brachialis muscle, whereas the upper and posterior process, the olecranon, gives insertion to the powerful extensor of the forearm, the triceps muscle from the back of the arm. Immediately behind the trochlear notch on the lateral side of the ulna is the radial notch for articulation with the margin of the head of the radius. The shaft of the bone has three surfaces giving attachment to muscles which act upon the wrist and fingers and in the movements of both pronation and supination. The sharp lateral margin of the shaft gives attachment to the interosseous membrane. The lower end, or head, of the ulna, much smaller than the upper, has a styloid process and an articular surface, the lateral surface of which meets the lower end of the radius. The lower part is in contact with a fibrocartilage which binds the ulna to the radius and separates the distal end of the former from the wrist joint.

The ulna, much more than the radius, establishes the hinge joint at the elbow. The radius, although entering into this joint, is involved, functionally, less with the arm than with the hand with which it alone articulates. By muscular action the radius revolves about the stationary ulna, carrying the hand in the movement called twisting the wrist. When the palm faces forward in supination, the radius and ulna are parallel. When it faces backward in pronation, the radius crosses obliquely over the ulna.

Hand.—The hand consists of the carpus, or wrist; the metacarpus, or palm; and the five digits individually named. Anatomists describe it with the palm turned to the front, and with its long axis in line with the long axis of the forearm.

The eight carpal bones are arranged in two rows. Named in order from the radial to the ulnar side, the proximal row comprises the scaphoid, lunate, triquetral, and pisiform bones, and the distal row the trapezium, trapezoid, capitate, and hamate bones.

The five metacarpal bones are miniature long bones. The metacarpal of the thumb is the shortest, and diverges outward from the rest; its carpal extremity is saddle-shaped for articulation with the trapezium. Its shaft is somewhat flattened, and its distal end is smooth and rounded, articulating with the first phalanx of the thumb. The bases of the other metacarpal bones articulate with the trapezoid, capitate, and hamate bones; the distal end or head of each articulates with the proximal phalanx of a finger.

The five digits of the hand are called, by anatomists, the pollex, index, medius, annularis, and minimus—popularly, the thumb and the index, middle, ring, and little finger. The skeleton of the thumb consists of two phalanges while that of each finger has three. Each phalanx is a miniature long bone.

The carpal bones although firmly joined together, are nevertheless capable of slight movements that are essential in the mechanism of the hand as a grasping organ. The palmar contour of the wrist skeleton is like a gutter, bridged over by a dense ligament that makes it into a tunnel through which pass blood vessels, nerves and tendons for the fingers. The thumb has a great range and variety of movement, a human characteristic made possible in part by the conformation of the base of its metacarpal with the trapezium. The other carpometacarpal joints permit only slight motion, in contrast with the free movement of the fingers.

B. Lower Limb

The bones of the lower limb are the hipbone, the femur of the thigh, the patella of the knee, the tibia and fibula of the lower leg, and the numerous bones of the foot.

Hipbone.—The hipbone (also called the innominate bone or os coxae) is a large irregular plate which forms the lateral and anterior wall of the pelvis (*see* below). In early life it is made up of three separate elements—ilium, ischium, and pubis—which unite about the 18th to the 20th year into a single bone. At the site of junction of the three elements there is a cup-shaped depression, the acetabulum, for the head of the femur (*see* fig. 3, 4). From the acetabulum the ilium extends upward and laterally, the ischium downward, the pubis forward and medially. Below the acetabulum is a large opening, the obturator foramen, bounded by the pubis, the ischium, and the ilium.

Ilium.—The ilium is a broad, bony plate, the lower, narrower part of which enters into the formation of the acetabulum, whereas the upper, expanded part presents an elongated free margin, the sinuous crest of the ilium. This crest affords attachment to the broad muscles that form the wall of the abdominal cavity. The external or lateral surface of the ilium gives origin to the muscles of the buttock. The internal surface is hollowed out anteriorly and gives origin to the iliacus muscle, which flexes the thigh. Posteriorly the ilium has an L-shaped surface articulating with the side of the sacrum in the sacroiliac joint.

Pubis.—The pubis consists of a body (main portion) and two rami (secondary structures arising from the body) and is therefore somewhat U-shaped. The body is the flattened portion adjacent to the symphysis, and has an outer and an inner surface. The upper ramus passes backward to become continuous with the ilium; the lower ramus is continuous with the ramus of the ischium.

Ischium.—The ischium also is somewhat U-shaped. The upper extremity completes the acetabulum, whereas the lower is united with the inferior ramus of the pubis, and together these form the lower boundary of the obturator foramen. The conjoined rami afford origin to the adductor muscles that act in drawing the thigh toward the middle line. The upper, posterior branch is a stout bone which gives origin to the powerful hamstring muscles of the back of the thigh. The spine of the ischium separates the greater from the lesser sciatic notch. In the sitting position the body rests on a tuberosity on the back of the ischium.

Pelvic Girdle.—Articulation of the hipbones with each other at the pubic symphysis, and with the sides of the sacrum behind, forms the pelvic girdle—the bony walls of the lower body cavity known as the pelvis. (This term is popularly but incorrectly applied to the hipbone or to the pelvic girdle, rather than to the cavity which the bones define.) The pelvis is subdivided into a major (false) and a minor (true) pelvis. The true pelvis encloses a short, wide canal and possesses a superior opening, or inlet, a cavity and an inferior opening, or outlet. The false pelvis consists of the iliac fossa (concavity) of each side above the level of the inlet of the true pelvis. Because of the inclination of the pelvis, the upper part of the sacrum is nearly 10 cm. (4 in.) higher than the upper margin of the pubic symphysis. The female pelvis is distinguished from the male by certain sexual characteristics

The bones are more delicate and the ridges and processes for muscular attachment are less prominent. The depth is less, the inlet more nearly circular, the pubic arch wider, the distance between the ischial tuberosities greater and the acetabulum smaller in the female than in the male. In addition, the pelvis is broader and its capacity greater, and this contributes to the greater breadth of the hips in women. The greater capacity of the female pelvis affords room for expansion of the uterus during pregnancy and for the passage of the child at the time of birth.

Femur.—The femur is the longest bone in the body. At its upper extremity is the smooth hemispherical head, articulating with the acetabulum. Supporting the head is a strong, elongated neck which extends downward and outward to join the shaft. At the junction of neck and shaft two processes, the trochanters, are situated. To the lateral, or greater, trochanter are attached muscles that rotate the thigh; into the lesser trochanter is inserted the iliopsoas muscle, a flexor of the thigh. The neck of the femur in the adult forms an angle of about 125° with the shaft. The shaft is almost cylindrical at its centre, but it is expanded above and below. Its front and sides give origin to the extensor muscles of the leg; behind, there is a long ridge, the linea aspera, into which are inserted the adductor muscles of the thigh. The lower end of the femur is adapted to the upper surface of the tibia and presents a large, smooth, articular surface, the anterior portion forming a trochlea (pulley) for the patella. The lower and posterior part, subdivided into two condyles (rounded projections), moves upon the condyles of the head of the tibia. In the deep fossa between the femoral condyles are attached the cruciate ligaments that control and limit movements at the knee joint.

Patella.—The patella, or kneecap, is a triangular, flattened bone of the sesamoid type (*see* below) developed in the tendon of the great extensor muscles of the leg. Its anterior surface and sides are rough, giving attachment to tendinous fibres; its posterior surface is smooth, and enters into the formation of the knee joint by articulating with the anterior part of the lower end of the femur.

Tibia.—The tibia, or shin bone, is the medial and larger of the two bones of the lower leg. The femur moves and rests upon its upper end, and through it the weight of the body in the erect position is transmitted to the foot. Its upper extremity (head) is broad and expanded into two condyles, the lateral one bearing inferiorly a small articular facet for the head of the fibula. Superiorly, the two condyles have nearly flat surfaces, articulating with the condyles of the femur. The two condyles are separated by an intermediate rough surface, from which an intercondyloid eminence projects; standing opposite the intercondylar fossa of the femur, this eminence affords attachments to the interarticular cruciate ligaments and the meniscoid cartilages of the knee. These cartilages are movable rings which help to compensate for the flatness of the condylar articular surfaces by making shallow sockets for the femoral condyles. The shaft of the tibia is three-sided. Its medial surface is subcutaneous and forms the shin. Its lateral and posterior surfaces give origin to muscles which move the foot. The anterior margin is the sharp ridge of the shin, and terminates superiorly in a tubercle into which the great tendon of the extensor muscles of the leg is inserted. The lateral margin of the bone gives attachment to the interosseous membrane of the leg. The lower end of the tibia, smaller than the upper, is prolonged into a broad process, the medial malleolus, which forms the inner prominence of the ankle. The lower end of the tibia articulates with the talus.

Fibula.—The fibula is the long, slender bone buried in the muscles of the outer side of the leg. The upper end articulates with the lateral condyle of the tibia. The shaft is four-sided and gives attachment to many muscles. Separating the anterior from the medial surface is a slender ridge giving attachment to the interosseous membrane. The lower end expands into a strong process, the lateral malleolus, forming the lateral prominence of the ankle and presenting a smooth medial surface articulating with the talus. Behind this is a rough surface where the strong ligaments that bind the tibia and fibula together are attached.

Foot.—The foot consists of the tarsus, the metatarsus, and the five free digits, or toes. The human foot is placed in the prone position, with the back of the foot directed upward. The axis of the foot is at about a right angle to the axis of the leg, and the great toe, or hallux, corresponds to the thumb.

The seven bones of the tarsus, or ankle, are arranged in three transverse rows: a proximal, consisting of the talus and calcaneus; a middle, consisting of the navicular; and a distal, composed of the first, second, and third cuneiform bones and the cuboid bone. The tarsal bones like the carpal bones are short and, with the exception of the wedge-shaped cuneiforms, are irregularly cuboidal. The dorsal and plantar surfaces of most of these bones are rough for the attachment of ligaments; the exception is the talus which, since it is mortised between the bones of the leg and the calcaneus, presents smooth articular surfaces on its dorsal and plantar surfaces as well as on its sides.

The posterior portion of the calcaneus projects backward to form the prominence of the heel. With this exception the tarsal bones have articular surfaces upon their anterior and posterior surfaces. Their lateral and medial surfaces are also articular, excepting the lateral surfaces of the calcaneus and cuboid, which

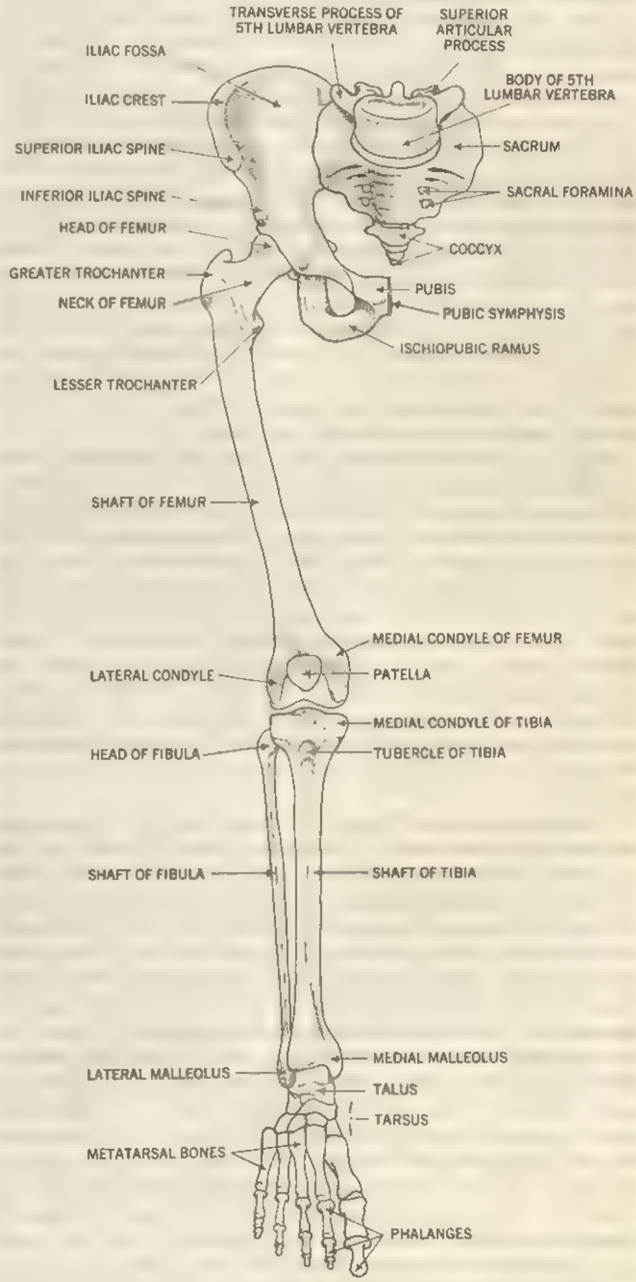

FIG. 5.—FRONT VIEW OF SKELETON SHOWING RIGHT HALF OF THE PELVIC GIRDLE AND RIGHT LOWER LIMB

form the outer margin of the tarsus, and the medial surfaces of the calcaneus, navicular, and first cuneiform, which form the inner margin.

The metatarsal bones and phalanges agree in number and in general form with the metacarpal bones and the phalanges in the hand. The bones of the great toe are more massive than those of the other digits, and this digit, unlike the thumb, does not diverge from the other digits but lies almost parallel with them.

C. Sesamoid Bones

In addition to the bones described above, certain supernumerary bones develop in certain tendons of the muscles of the hand and foot; these are known as sesamoid bones. The patella also originates in tendinous tissue, and is therefore sesamoid in character; it begins to ossify about the third year.

IV. EMBRYOLOGY

The skeleton is developed from the embryonic mesoderm, so it is necessary to refer briefly to the origin of this tissue. At about the 15th day after fertilization of the ovum, when the embryo consists of a bilaminar disc with layers called ectoderm and endoderm, a longitudinal thickening appears in the posterior part of the embryonic disc as the result of multiplication of the ectodermal cells. This thickening, called the primitive streak, gives rise to the notochord and to the mesoderm. The primitive streak is comparable to the blastopore of lower vertebrate embryos. The axis of the embryo is first laid down by the formation of a cylindrical mass of cells, the notochord, proliferated from the primitive (Hensen's) node at the anterior end of the primitive streak. The notochord lies ventral to the developing central nervous system and forms the first supporting structure for the developing embryo.

In fishes such as the shark, cartilaginous vertebrae are formed round the notochord and to some extent compress it. Nevertheless, it persists as a continuous structure through the length of the vertebral column. In the higher vertebrates, including man, the notochord is a temporary structure which persists only as a minute canal in the bodies of the vertebrae and in the central part of the nucleus pulposus of the intervertebral discs.

While the notochord is being laid down, cells proliferate from the sides of the primitive streak. These form the mesoderm, which spreads out as a sheet on each side and, as a result of migration and multiplication of cells, soon comes to occupy most of the space between the ectoderm and the endoderm on each side of the notochord. The mesodermal sheets soon become differentiated into: (1) a mass lying on each side of the notochord (paraxial mass) which undergoes segmentation into hollow blocks, the mesodermal somites; (2) a lateral plate which becomes separated into an outer layer, the somatopleuric mesoderm, against the future body wall, and an inner layer, the splanchnopleuric mesoderm, against the endoderm of the future gut; (3) an intermediate mass, the nephrogenic cord, which gives rise mainly to the urinary apparatus.

The segmentation of the paraxial mesoderm is a fundamental feature of the development of the vertebrates. The axial skeleton and associated structures develop from part of the somite, while the appendicular skeleton arises from the somatopleuric mesoderm of the lateral plate. Each somite differentiates into: (1) a lateral and superficial plaque, the dermatome, giving rise to the integumentary tissue; (2) a deeper lateral mass, the myotome, which gives origin to the muscles; and (3) a medial ventral mass, the sclerotome. The sclerotomic cells from each pair of somites migrate medially until they meet in the middle line round the notochord to separate it from the neural tube dorsally and from the aorta ventrally. The sclerotomic tissue retains its original segmentation and becomes condensed to form the forerunner or blastema of the body of the future vertebra. From each posterolateral half of the condensation extensions pass backward and eventually meet posteriorly round the neural tube to form the blastema of the neural arch of the vertebra. In the interspaces between adjacent myotomes of each side, an extension from each sclerotomic mass passes laterally and forward to form the costal or rib element. It is only in the thoracic region that the costal elements develop into the definitive ribs. In the other regions the costal elements remain rudimentary. As early as the seventh week of fetal life the mesenchymal blastema of the future vertebra becomes chondrified; *i.e.*, the mesenchymal cells are converted into cartilage cells. In this cartilaginous vertebra, ossification centres appear about two weeks later, and the cartilage is gradually replaced by bone. The mesenchyme of the primordia of the ribs also undergoes chondrification and later ossification. In the thoracic region, where costal elements are best developed, a cartilaginous sternal bar is formed in relationship with their anterior or growing ends.

The appendicular skeleton begins to develop in the primitive limb bud at the fifth week of fetal life in the core of mesenchyme derived directly from the unsegmented somatopleuric mesoderm. This mesenchyme becomes condensed to form the blastemal masses of the future limb bones. By the seventh week of fetal life, the mesenchyme has become transformed into the cartilaginous precursors of the individual bones (except in the case of the clavicle). The cartilaginous models determine the general shape and relative size of the bones, and there is convincing evidence from experimental investigations that the shape of the bones of higher vertebrates is determined by intrinsic factors inherent in the tissues and that extrinsic influences are concerned with providing the proper conditions for maintaining the normal structure once development has begun.

The first mesenchymal condensations of the appendicular skeleton are in the region of the future girdles, and those for the shoulder girdle appear a little earlier than those for the pelvic girdle. The mesenchymal condensations for the other bones of the limbs appear in a proximodistal sequence.

Ossification of Bone.—The ossification of bone is usually described as occurring by two different methods: endochondral (in cartilage) and intramembranous (in membrane). However, the fundamental process is the same for both, since the cells that are responsible are identical.

All the bones of the skeleton (excluding certain of the skull bones and the clavicle) are developed in cartilage; *i.e.*, by endochondral ossification. It must be emphasized that there is no direct transformation of the cartilage into bone. The cartilage of the model becomes calcified and is then removed by a process of erosion and replaced by bone (*see* Bone; Connective and Supporting Tissues: *Anatomical Types of Connective Tissues: Bone*).

V. COMPARATIVE ANATOMY

A. Vertebral Column and Thoracic Skeleton

Just as in the embryonic development of man the notochord forms the earliest structure that stiffens the embryo, so in the animal kingdom it appears before the true vertebral column is evolved.

Lower Chordates and Fishes.—Possession of the notochord distinguishes members of the most advanced phylum, Chordata. In the ascidians or sea squirts (subphylum Urochordata) the notochord is present in the larval stage, in the tail region only, disappearing after the animal's metamorphosis to the adult form. In amphioxus (subphylum Cephalochordata) the notochord is permanent and extends the whole length of the animal. In the cyclostome fishes (class Agnatha, the most primitive group within the subphylum Vertebrata) the notochord and its sheath persist throughout life, and in the adult lamprey rudimentary cartilaginous neural arches are found. Among the sharks (class Chondrichthyes) modern representatives possess a vertebral column composed of cartilaginous, partly calcified, centra which have their origin within the sheath of the notochord, causing its partial absorption. Among the bony fishes (class Osteichthyes) the sturgeon has a persistent notochord with fibrous sheath upon which appear paired cartilaginous arches: dorsally, the neural arches and, ventrally, the hemal arches. The vertebrae of the more advanced bony fishes, such as the salmon and cod, are completely ossified; each centrum develops in the sclerotomic mesoderm outside the notochordal sheath (perichordal development).

Amphibians.—A vertebra of a modern tailed amphibian is

in one piece, and the neural and hemal arches are in continuity with the centrum. In general, a vertebra is formed from the sclerotomic tissue of two somites, the tissue from the posterior part of one somite joining that from the anterior part of an adjacent one. Articulation between neural arches of adjacent vertebrae is by special articular processes (zygapophyses). The first vertebra of the amphibian vertebral column, the atlas, presents a pair of sockets on the anterior surface of the centrum. These sockets articulate with the two condyles of the skull. The second vertebra does not differ from those following.

Reptiles.—In living reptiles the vertebrae are completely ossified. The neural arch has a spinous process and pre- and postzygapophyses; at the junction of arch and centrum there is a facet for articulation of the head of a rib. Groups of vertebrae can be distinguished; *e.g.*, the cervical vertebrae can be recognized, as the neck is differentiated from the body. The atlas, in the form of a ring, lacks a centrum, and articulates with the single condyle of the skull by a facet on the anterior surface of the ventral bar of the ring. The second vertebra, the axis, possesses a centrum which articulates anteriorly with the odontoid process; this process is the dissociated centrum of the atlas and lies within the ring of the latter in contact with its ventral bar. The costal elements of two sacral vertebrae unite the pelvic girdle with the axial skeleton. In the tail region hemal arches are found enclosing the caudal artery and vein. In some species the hemal arches are separate and are called chevron bones. A special feature of the caudal vertebrae in the lizard is the transverse division of the centra, adapted to the shedding of the tail.

The fibrocartilaginous intervertebral discs uniting the centra of crocodiles have been identified as representing intercentra (interpreted as ossifications in the hypochordal bars). Ribs are present in the cervical, thoracic, and lumbar regions, and in the tortoises they fuse with the cervical vertebrae. The more cranial thoracic ribs are attached to the sternum through cartilaginous sternal ribs; the other ribs do not reach the sternum. In the crocodiles and the lizardlike *Sphenodon*, a spur from each thoracic rib overlaps the next rib behind and is known as an uncinate process. These processes are developed in connection with the origin of the external oblique muscle of the abdomen. The ventral elements of some of the hinder ribs of crocodiles lie unattached in the intersections of the rectus and internal oblique muscles and are known as abdominal ribs.

The sternum may be calcified but is seldom ossified in the reptiles. In the lizards it is a cartilaginous plate articulated with the coracoid processes of the pectoral girdle and with the anterior thoracic ribs. The sternum is absent in the turtles and in the snakes; in the crocodiles it is a wide plate joined by the coracoids and by two pairs of ribs.

Birds.—The skeletons of modern birds show reptilian features with some specialized adaptations to their bipedal locomotion and power of flight. Between the bodies of the vertebrae are intervertebral discs. The neck is very movable, and with its variation in length the number of cervical vertebrae ranges from 25 in the swan to only 9 in some of the small birds. The tendency for the vertebrae to fuse in certain regions is a characteristic of birds. The two true sacral vertebrae become secondarily fused with adjacent lumbar vertebrae, and indirectly even with thoracic, to constitute a synsacrum. This fuses with the ilium of the pelvic girdle, making a rigid support for the posterior part of the bird's body. The caudal vertebrae are fused into a single bone, the pygostyle, that supports the tail. The sternum is a very large bone standing like a shield in the front of the chest. In flying birds a median keel, the carina, projects ventrally, providing additional surface for the attachment of the pectoral muscles that move the wings. The flightless birds, such as the ostrich, have a keelless, raftlike sternum.

Mammals.—In mammals, the vertebral centra articulate by means of intervertebral discs of fibrocartilage. Epiphyseal bony plates formed on the generally flat ends of the centra are characteristic of mammals; they are rudimentary in the duck-billed platypus and in the sea cows. Regional differentiation in the mammalian backbone is marked. The number of vertebrae in each group, excepting the caudal, is moderately consistent with few exceptions. Some exceptions to the group averages may be cited. Whereas 7 cervical vertebrae are the rule, there are 9 or 10 in the three-toed sloth and only 6 in the two-toed sloth and the manatee. The thoracic vertebrae commonly number 13 or 14, although they vary from 9 in some whales to 24 in the two-toed sloth. The average number of lumbar vertebrae may be taken as 6; there are but 2 in the duck-billed platypus and 21 in the dolphin. Rib elements are fused to the transverse processes of the cervical vertebrae, and in the lumbar vertebrae they form the so-called transverse processes.

There is an increase in the number of vertebrae that compose the sacrum. In the early developmental stages of human embryos the beginnings of the hipbones lie opposite those segments of the spinal column that go to form the lower lumbar and upper sacral vertebrae. As development proceeds, the sacroiliac joints become established between the hipbones and the upper sacral vertebrae; the sacrum, derived from the 25th to the 29th vertebrae inclusive, becomes a single bone by their fusion. The whales and sea cows lack a sacrum, although vestiges of a pelvis occur. In some anteaters the posterior sacral vertebrae are fused with the ischium through ossification of the sacrotuberous ligament. The sacrum of some armadillos consists of 13 vertebrae, caudal vertebrae having become fused with it. The cervical vertebrae of some whales are fused together. The centrum of the atlas of most mammals fuses with that of the axis and projects from it as the dens, but in the duck-billed platypus it is a separate bone as it is in reptiles.

The spinous processes of the thoracic vertebrae, excepting the last, point caudally and those of the lumbars generally point cranially; at the transitional zone between these groups the spines of one or two thoracic vertebrae are upright and the name anticlinal is given to them. Lying ventral to the intervertebral discs in some mammals (whales, pangolin) are paired ossicles, the intercentra, homologous with the anterior arch of the atlas. The tail vertebrae vary in number from none in the bat to 49 in the pangolin.

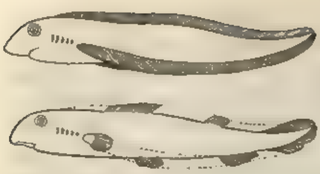
The ribs in mammals correspond in number of pairs to the number of thoracic vertebrae. The tubercle articulates with the transverse process; the head of the rib with the capitular facets of two vertebrae, that with which the tubercle articulates and the one anterior to it. The ribs of some whales articulate only with the transverse processes of the vertebrae. The ventral ends of the ribs join the costal cartilages, the relations of which follow, with minor variations, the pattern described for the human skeleton. Sternal ribs, connecting the more anterior vertebral ribs with the sternum, may be cartilaginous, calcified, or ossified. The mammalian sternum is composed of several pieces: the presternum anteriorly, followed by the mesosternum, made up of a number of segments, and a terminal single xiphisternum. The sternum of the rorqual whale and of the manatee is a single bone.

B. Appendicular Skeleton

The paired appendages are not found in ancestral vertebrates and are not yet present in the living cyclostomes. Appendages make their first appearance during the early evolution of the fishes. Usually two pairs of appendages are present and consist of fins in the fishes and limbs in land vertebrates. Each appendage includes not only the skeletal elements within the free portion of the limb but also the basal supporting structure, the limb girdle. This portion of the appendage lies partly or wholly within the trunk and forms a stable base for the fin or limb. Each girdle consists of ventral and dorsal masses. In lower fishes these are composed of cartilage; in bony fishes and in land vertebrates the masses become partly or completely ossified.

The anterior appendages, the pectoral fins or forelimbs, articulate with the pectoral girdle, which is situated just behind the gill region in fishes and in a comparable position at the junction of the neck and thorax in land vertebrates.

The posterior appendages, called pelvic fins or hindlimbs, articulate with the pelvic girdle, which is situated in the trunk region usually just in front of the anus or cloaca. It is by way of the girdles that the weight of the body in land vertebrates is trans-



FROM H. H. WILDER, "HISTORY OF THE HUMAN BODY"; HOLT, RINEHART & WINSTON, INC.

FIG. 6.—THE THEORY OF ORIGIN OF MEDIAN AND PAIRED FINS OF THE FISH AS THE RESULT OF PERSISTENCE OF CERTAIN PARTS OF THE MEDIAN AND LATERAL FIN FOLDS

mitted to the limbs. As the hind limb is usually of greater importance in weight bearing, especially in bipedal vertebrates, it articulates with the vertebral column by means of the costal elements of the sacral vertebrae. The vertebrae to which the pelvic girdle is attached usually fuse to form the sacrum. In fishes, however, since the posterior appendages usually do not support the body weight but are used only in locomotion, a sacrum as such does not develop.

The origin of paired fins has been much debated and many theories have been put forward in explanation. According to the widely accepted fin-fold theory, the paired limbs are derived from the local persistence of parts of a continuous fold which, in ancestral vertebrates, passed along each side of the trunk and fused behind the anus into a single fin (*see* fig. 6). The primitive paired fins were attached to the body by a broad base and carried no weight. Their main function, it would appear, was to act as horizontal stabilizing keels which tended to prevent rolling movements and possibly also fore and aft pitching.

It is generally agreed that the limbs of land vertebrates evolved from the paired fins of fishes. They are thought to have their ancestral counterpart in the fins (*see* fig. 7) of certain lobe-finned fishes (Crossopterygii, a nearly extinct group of which the coelacanth is a living example). The skeleton of the primitive fin consists of a series of endoskeletal rods each of which undergoes subdivision into a series of three or four pieces. The basal pieces tend to fuse into larger pieces. The most anterior of the basal pieces fuses across the middle line with its fellow of the opposite

FIG. 7.—RIGHT PECTORAL GIRDLE AND FIN OF AN EXTINCT CROSSOPTERYGIAN FISH (SAURIPTERUS)

side to form a primitive girdle in the form of a cartilaginous bar. The more distal pieces persist to form the dermal fin rays.

Pectoral Girdle.—*Fishes.*—In a cartilaginous fish such as the dogfish the pectoral girdle consists of a U-shaped endoskeletal cartilaginous inverted arch with its ends extending dorsally (*see* fig. 8). The crosspiece of the "U" forms the coracoid bar, the ends passing dorsally on each side to form the scapular processes. At the junction of the coracoid with the scapular process is an articular region, the glenoid cavity, for articulation with the basal cartilages of the fin.

In all other major groups of vertebrates the pectoral girdle is a composite structure consisting of the endoskeletal structures to which secondary dermal components are added as the result of ossification of dermal elements. These become ossified to form dermal bones. In primitive bony fishes such as the lungfishes, sturgeon, and coelacanths, the main element added is a vertically placed structure, the cleithrum, which supports the scapula (*see* fig. 9). The cleithrum may be joined by a supracleithrum, which in turn is surmounted by a posttemporal element, so that the shoulder girdle is connected with the rearward sides of the skull. The most ventral of the added dermal bones are the clavicles, which unite below the gill chamber with each other or with the sternum. In the holostean fishes (*e.g.*, gar pike) and in the teleosts (*e.g.*, salmon and codfish) the clavicle is lost, leaving only the cleithrum.

FIG. 8.—LEFT PECTORAL GIRDLE AND FIN OF A CARTILAGINOUS FISH

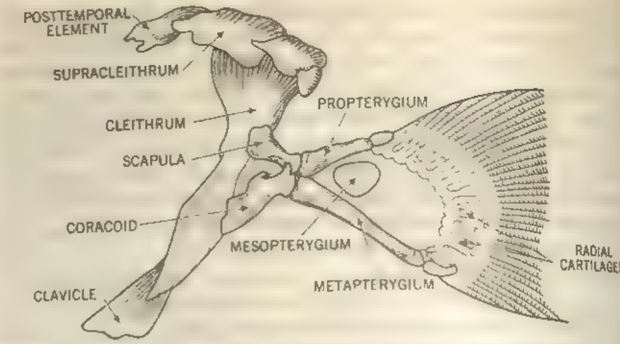

FIG. 9.—RIGHT PECTORAL GIRDLE OF A TELEOST FISH

Amphibians.—In tailed amphibians such as newts and salamanders the dermal elements of the pectoral girdle have been completely lost and only the endoskeletal parts remain; they have reverted mainly to being cartilaginous bars. This retrogression is probably the result of their adaptation chiefly to an aquatic mode of life where less support by the girdles is required. The ventral part of the girdle forms the coracoid and the dorsal part the scapula; the latter is the only part which becomes ossified, and only a rudimentary sternum is developed.

In the frog, the pectoral girdle consists of a dorsally placed, ossified scapula, to the end of which is joined an incompletely ossified plate, the suprascapula. The precoracoid and coracoid are quite distinct, the former being cartilaginous and overlaid by an investing dermal bone, the clavicle.

Reptiles.—In most reptiles there is a primary girdle for the forelimb, consisting of a scapula and a single coracoid. The pectoral girdle of the lizard consists of bones formed in cartilage the scapula and the large coracoid, participating in the glenoid cavity; and the dermal bones, the clavicle and interclavicle the latter being a single T-shaped bone, with the stem in the midline and in contact with the sternum. The curved clavicles articulate with each other at their medial ends. The cartilaginous suprascapula is present.

In the alligator the pectoral girdle consists of a stout dorsal scapula and a well-developed precoracoid. Clavicles are absent, but there is a well-developed midventral dagger-shaped interclavicle.

Birds.—In birds the pectoral girdle is essentially similar to that found in the reptiles. The precoracoid forms a stout bar which reaches to the sternum. The wishbone, or furcula, is formed from the dermal part of the girdle and consists of two clavicles united together in the middle line by the interclavicle. Carinate birds (those with a keeled sternum) have a sabre-shaped scapula and a stout coracoid joined together by ligaments, where the glenoid cavity for articulation with the humerus is located. The coracoid is jointed to the sternum; at its dorsal end is the acrocoracoid process. The furcula stands in front of the coracoids, its ends connected by ligaments with the acrocoracoid and with the rudimentary acromion process of the scapula. The girdle of the flightless ratite birds (those with a flat sternum) is little developed, being represented by an ankylosed scapula and coracoid.

Mammals.—Among mammals, the monotremes have two coracoids, articulating medially with the presternum and laterally with the scapula, which enter into the formation of the glenoid cavity. An interclavicle (episternum) and an investing clavicle resembling these bones in reptiles are also present. The clavicle articulates with the acromion of the scapula. In the opossum the scapula has a spine ending in the acromion, with which the clavicle articulates

A much-reduced coracoid fuses with the scapula and does not meet the sternum. The scapula of the placental mammals has a spine ending, generally, in an acromion, and the body of the bone is triangular. In mammals which use the forelimb for support in standing, the vertebral margin is the shortest and the long axis of the scapula runs from it to the glenoid cavity; but in those whose forelimb is used for prehension, such as the primates, or for flight, such as the bats, the vertebral margin is elongated and the distance from it to the glenoid cavity is decreased, so that the long axis is parallel with that of the body instead of being transverse. In the placental mammals, the coracoid, although developing independently, has dwindled to a beaklike process, and fuses with and becomes part of the scapula and does not articulate with the sternum. There has occurred a change in the structure of the pectoral girdle, from its form in animals (*e.g.*, reptiles) in which the forepart of the body is propped up on the forelimbs and in which the coracoid is functional, to its form in pronograde mammals (those which carry the body horizontally) in which the foreparts are suspended between the two scapulas by the serratus anterior muscles. These muscles spring from the ribs and are inserted into the vertebral margin of each scapula.

The clavicle is present generally in those placental mammals that have prehensile forelimbs (primates, many rodents and marsupials, and others), or whose forelimbs are adapted for flying (bats). In many mammals it is suppressed, as in cats, or absent, as in whales, sea cows, and hoofed animals.

Pelvic Girdle.—*Fishes.*—The pelvic girdle of the elasmobranch fishes consists of a curved cartilaginous puboischial bar or pair of bars lying transversely in the ventral part of the body anterior to the cloaca; projecting dorsally on each side is an iliac process. Connected with it is a basal cartilage carrying a series of radialia, the skeleton of the paired pelvic fins. The pelvic girdles of many bony fishes are situated far forward near the gills.

Amphibians.—There are marked variations in the form of the pelvic girdle in the amphibians. In the frog the three parts of the hipbone (ilium, ischium, and pubis) are present. The public elements, however, remain wholly cartilaginous. The hipbone is characterized by the great length and forward extension of the ilium. The girdle is connected with the costal element of one vertebra, thus establishing a sacral region of the vertebral column. The acetabulum is situated at the junction of the three elements.

Reptiles.—The pelvic girdle of some reptiles has a loose connection with the spine. In most reptiles, the ilium is joined to two sacral vertebrae. Both the pubic and the ischial parts usually meet in the ventral symphysis, from which a cartilage or bone, the hypoischium, projects backward to support the margin of the cloacal orifice, and another, the epipubis, projects forward. A few snakes (*e.g.*, boas) retain vestiges of a pelvic girdle and limb skeleton.

Birds.—In most birds the ilium extends forward and backward and is fused with the many vertebrae which form a synsacrum. The slender ischia and pubes do not form symphyses except in the ostrich.

Mammals.—In most mammals the ilium articulates with the sacrum and the pubes meet in a symphysis anteriorly. A cotyloid bone, formed in the cartilage in the bottom of the acetabulum, is usually found. The symphysis pubis is not present in certain mammals (*e.g.*, moles). In monotremes and marsupials, the marsupial bones that support the pouch have been regarded as part of the epipubis.

Limbs.—*Fishes.*—The pectoral fin of the elasmobranchs has basal cartilages articulating with the pectoral girdle and carrying a number of radial cartilages consisting of varying numbers of short segments beyond which are delicate fin rays (*see* fig. 8).

The proximal segment of the pelvic fin of sharks is supported by a single basal cartilage and by one or two radialia. In the pectoral fin of the primitive ray-finned fish *Polypterus*, three elements constitute the proximal segment of the fin, bony rods named propterygium and metapterygium on the margins and an intermediate cartilage partly ossified, the mesopterygium (*see* fig. 9).

Other Vertebrates.—In the land vertebrates, many modifications have occurred in the appendages as a result of the transformation of the fins from balancing organs to weight-bearing propulsive levers. Limbs with digits replace the paired fins. The position of the limbs undergoes progressive changes in adaptation to new conditions. The skeleton of the free limb of the land vertebrate is divisible into three segments: proximal, medial, and distal.

The proximal segment consists of a single bone, known as the humerus in the forelimb and as the femur in the hindlimb. The humerus articulates by its rounded head with the glenoid cavity of the scapula and by condyles with the bones of the forearm. Its shaft is usually twisted and presents ridges and tuberosities for the attachment of muscles. In many species the distal expanded end is perforated by epicondylar foramina. Foramina are characteristic of the humerus of most reptiles; an internal (entepicondylar) foramen is characteristic of some. These foramina are absent in crocodiles. The humerus of flying (carinate) birds is, like many of their bones, hollow and contains air. It is short and has, next to the head, a large tuberosity for the insertion of wing muscles. Epicondylar foramina are absent. In nonflying (ratite) birds, the skeleton of the wing is greatly reduced. The entepicondylar foramen is widely distributed among mammalian orders and seems to be linked, in part, with the prehensile limb, as is suggested by its presence in cats and absence in dogs and in the hoofed animals. The entepicondylar foramen transmits the median nerve and brachial artery. The supracondylar process sometimes found in man is a vestige of the boundary of the foramen.

The femur is essentially a cylindrical structure with expanded ends. At the proximal end, for articulation with the acetabulum, is the rounded head, and near it there are usually two elevations (trochanters) for the attachment of muscles. The occurrence of three trochanters is characteristic of certain mammals; *e.g.*, horse and rhinoceros. Distally, the femur expands into two condyles for articulation with the tibia. In many types there is an articular facet on the lateral surface for the head of the fibula.

The medial segment of the limb typically contains two bones, radius and ulna in the forelimb and tibia and fibula in the hindlimb. In the forelimb, the radius is anterior or preaxial, and the ulna postaxial in the adjustment of the limb for support and locomotion on land. The radius and ulna are fused in the tailless amphibians (*e.g.*, frogs) and are separate in those with tails (*e.g.*, salamanders), as they are in all of the reptiles. The ulna is the stouter bone in the bird's wing and supports the secondary feathers. In pronograde mammals the radius is fixed in pronation; *i.e.*, the forelimb is rotated so that the shaft of the radius crosses in front of that of the ulna. The radius transmits the weight of the forepart of the body to the forefeet; whereas it is the ulna that makes the elbow joint with the humerus, and into its proximal end are inserted the flexor and extensor muscles of the forelimb.

Tibia and fibula are separate in urodeles, united in tailless amphibians. In land reptiles the tibia articulates with both condyles of the femur and with the tritibiale of the ankle; the fibula articulates with the postaxial femoral condyle and with the tritibiale and fibulare. The tibia of birds is long, the fibula reduced. In mammals the fibula is generally reduced, and it may be fused with the tibia and excluded from the knee joint.

The distal segment of the limb comprises the carpus, metacarpus, and phalanges in the forelimb, and the tarsus, metatarsus, and phalanges in the hind limb. In a typical limb there are five digits (fingers or toes) which contain the phalanges.

The carpus and tarsus of the higher vertebrates are probably derived from a primitive type by the fusion or suppression of certain of its elements (*see* fig. 10). The bones of a generalized carpus (or tarsus), as that of a tortoise and certain other reptiles, are in three transverse rows: a proximal row of three, named radiale (or tibiale), intermedium, and ulnare (or fibulare); a distal row of five carpalia (or tarsalia), numbered one to five from the radial (or tibial) margin; and an intermediate row of one or two centralia.

In many of the urodele amphibians (*e.g.*, salamanders) the carpus is generalized. In the frogs and toads, however, it is more specialized, only six carpals being present, the third, fourth, and fifth carpalia having probably fused with either or both centralia. In birds the radiale and ulnare are distinct, but the distal bones are fused with the metacarpus to form a carpometacarpus. In mam-

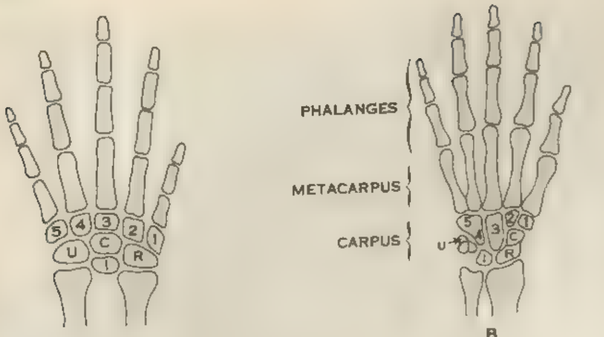

FIG. 10.—DISTAL SEGMENT OF FORELIMB SHOWING (A) PRIMITIVE CARPUS AND (B) HUMAN CARPUS

Key: R=radiale, I=intermedium, U=ulnare, C=centralis, 1–5=carpalia

mals various examples of fusion and suppression occur. In man the radiale forms the scaphoid; the intermedium, the lunate; the ulnare, the triquetral; the pisiform, an ulnar marginale, represents the remains of an extra digit, which may, however, be simply a sesamoid bone. The trapezium and trapezoid are carpalia 1 and 2; the capitate is derived from carpal 3, whereas carpalia 4 and 5 have fused to form the hamate. An os centrale is present in the carpus of many monkeys. In mammals the number of digits varies but the number of phalanges in each digit present usually corresponds with that of man. In some species, however, the phalanges are more numerous, as when the limb is modified to form a paddle (*e.g.*, in the whales).

The tarsus of urodele amphibians has the typical composition. In the frogs and toads the intermedium is absent; two long bones are identified as tibiale and fibulare. Among the reptiles there is much variation in the composition of the tarsus. Generally the hinge of the ankle is intratarsal, the row of tarsalia being distal to the hinge. In most living reptiles the tibiale and intermedium fuse to form the talus. In birds the ankle hinge is of the reptilian pattern in being intratarsal. The three tarsal cartilages of the embryo fuse to form the talus, which fuses with the tibia to form the tibiotarsus. The tarsalia fuse with the ends of the united metatarsals to make a tarsometatarsus. In the mammalian tarsus the talus is generally composed of the fused tibiale and intermedium, but in some a centrale is included to form a tritibiale. The ankle hinge is not intratarsal, but located between the bones of the leg and the first row of tarsal bones—tibia and talus usually.

Suppression of digits in hoofed mammals (*see* fig. 11) frequently has occurred in the following sequence: the pollex (first digit) is the first to go, then the minimus (fifth digit), index (second digit), and annularis (fourth digit). Thus, among the even-toed ungulates (artiodactyls; *e.g.*, pig and hippopotamus) the pollex has disappeared and the other four digits are present, although the second and fifth are much reduced. In the camel only the third and fourth digits persist and are of equal importance. Among the odd-toed ungulates (perissodactyls; *e.g.*, horse) the right digit is dominant and the others reduced to mere rudiments or splints.

(WM. J. H.; X.)

SKELTON, JOHN (*c.* 1460–1529), the only English poet of major importance between Chaucer and Wyatt, whose reputation, long misunderstood and misrepresented, has been restored by modern scholarship. Nothing is known of his parentage or place of birth. He was educated at Cambridge, and later attained the status of "poet laureate" (*i.e.*, a degree in rhetoric) at Oxford (*c.* 1488), at Louvain (between 1488 and 1493), and at Cambridge (1493). William Caxton, in 1490, in the preface to *Eneydos*, paid tribute to him for translating classical authors, notably Cicero's letters and Diodorus Siculus, into "polished and ornate terms." From all this early work, only his translation of Diodorus has survived; when first published, in 1956, it proved to be a notable piece of Tudor ornate prose, marked by considerable linguistic inventiveness.

JOHN SKELTON, FRONTISPIECE TO THE GARLANDE OF LAURELL, PRINTED BY RICHARD FAUKES, 1523

Skelton's success as rhetorician and translator led to royal patronage. From *c.* 1489 he was associated with Henry VII's court at Westminster, first as a court poet and later, in addition, as "scolemaster" to the duke of York (later Henry VIII), and possibly to his elder brother Arthur. When Skelton took holy orders in 1498, Henry VII made an offering of 20*s.* "at master Skelton's mass." Skelton took his tutorial duties seriously. In 1501 he composed a moral treatise for his pupils, the *Speculum Principis*, long accounted "lost," and unprinted till 1934. To this period must also belong his (still undiscovered) *New Gramer in Englysshe*. His reputation by the end of the 15th century was such that Erasmus, visiting England in 1499, referred to him as "the incomparable light and glory of English letters," and addressed him in a Latin panegyric as "Skelton, immortal bard, worthy of highest fame"—impressive tributes, even discounting the fashionable Humanist adulation.

The office of schoolmaster ceased in 1502, when Arthur's death made Henry heir to the throne, and his household was reorganized. Soon afterward Skelton became rector of Diss, in the diocese of Norwich, where his name appears in the records from 1504. Up to this point he was better known as translator and scholar than as poet. Of his extant works, a handful of lyrics probably belongs to this period, a group of court poems certainly (including an elegy on Henry Percy, earl of Northumberland). His only notable poem from this time at court was his *Bowge of Courte* (1498). This is medieval in form, a dream allegory in rime royal (*q.v.*). In content it is an exposure of the disheartening experience of life at court, and is Skelton's first considerable satire.

Skelton remained rector of Diss till his death, but was resident in London from 1512. Tradition and legend, perpetuated in the anonymous jestbook *Merie Tales Made by Master Skelton* (1567), portray him while in Diss as a lively buffoon. Modern research has dispelled this image. He figures in the Norwich records as an orthodox and responsible cleric, trusted by his superiors. Further

confirmation of his status came in 1504, when Cambridge followed Oxford in conferring on him the right to wear the habit granted by Henry VII.

The years at Diss produced a group of minor satires and two longer poems which established him as a new and, to some, a disconcerting poet. Both *Phillip Sparow* (written 1508) and *Ware the Hauke* (1504–12) broke new ground. In them he began the series of poems in short rhyming lines based on natural speech-rhythms, to which the name "Skeltonic" has been given. The contents demonstrate both his orthodoxy and his audacity:

Was never byrde in cage
More gentle of corage
In doing his homage
Unto his soverayne.
Alas, I say agayne,
Death has departed us twayne!
The false cat hath thee slayne:
Farewell, Phyllyp, adew!
Oure Lorde thy soule reskew!
Farewell without restore,
Farewell for evermore!

Phillip Sparow is a lament for the death of a young lady's pet bird. It is also a mockery of the Office for the Dead, and the "Commendations" for the soul of the dead in the Office have become complimentary commendations on the young lady. *Ware the Hauke* is an angry attack on an irreverent hunting priest who had flown his hawk into Skelton's church. In these poems the poet shows that the range of the new Skeltonic can include both tenderness and vituperation.

The accession of Henry VIII in 1509 turned Skelton's mind from satire back to compliment. He wrote complimentary verses both in Latin and English. He presented the king with a copy of the *Speculum Principis*, written while he was Henry's schoolmaster. He added a volume of the *Chronique de Rains* (a French chronicle of the life of Richard Coeur de Lion), with a dedication (from "Skelton Loyall") in his own hand. A note to the former complained that he was a man completely forgotten. Henry eventually responded. By *c.* 1512 he had conferred a new title on his old tutor, that of Orator Regius; the patent conferring it was seen by a French scholar in the 18th century, but (like so much documentation for Skelton) is now lost. But most of Skelton's poems from this time forward carry the new title as well as that of "poet laureate": he was letting no one forget either of his honours.

Some time after his arrival in London he acquired a house (*tenementum*) within the sanctuary of Westminster. The Westminster Abbey Register Book notes that he was living there in 1518; and, since in 1512, shortly after he resettled in London, he wrote a Latin epitaph on Henry VII at the request of the abbot of Westminster, it is likely that his occupation of the *tenementum* began in that year. He died in Westminster on June 21, 1529, and was buried in St. Margaret's. This continuous residence within the abbey precincts is of importance for the understanding of some of the later satires in which he attacked Cardinal Wolsey. One of the most persistent "legends" concerning Skelton is that Wolsey in revenge drove him to take sanctuary. Anthony à Wood, in his *Athenae Oxonienses* (1691), adds picturesque details, including a pursuit by Wolsey's officers. Like the *Merie Tales*, this has proved to be fiction: Skelton was, understandably, unpopular for a time with the cardinal, but he made his peace, and at no time had to flee to the sanctuary in which he had lived for many years.

The London years were Skelton's most productive. As Orator Regius he considered he had full licence to praise the king, attack the king's enemies, entertain him, and on occasion admonish him. The defeat of the Scots (whom Skelton loathed) at Flodden produced one of the few poems printed in his lifetime, the *Ballade of the Scottyshe kynge* (1513). This savage satire was revised and sharpened the following year as *Against the Scottes*. Skelton turned his considerable powers of poetical invective against the king's enemies. In the same year (1514) he entertained the court with a series of "flyting" poems of mock abuse, *Against Garnesche*, written "Be the kynges most noble commandement," so continuing a court-poet's exercise that goes back to the troubadours.

In 1516 Skelton wrote his longest contribution as court poet, a "goodly interlude and a mery" entitled *Magnyfycence*. This play (there is no record of performance) retains the old form of the morality, with a cast of allegorical abstractions (*see* DRAMA: *Medieval Drama*). It is the first secular morality in English. It is political satire and admonition in a new shape. Magnyfycence represents the king, and the Vices and Virtues are the two factions among his counselors. The extravagant claims of Wolsey are covertly attacked. As a drama, it must be presumed a failure, since it has apparently never been produced. But some of the serious scenes (*e.g.*, the fall of Magnyfycence) are impressive; and as a creator of stage comedy Skelton was ahead of his time.

In 1517, probably as court entertainment, he wrote *The Tunnynge of Elynour Rummyng*, a brilliant portrayal of drunken women in an alehouse:

But let us turne playne
There we lefte agayne.
For, as yll a patch as that,
The hennes run in the mashfat;
For they go to roust
Straight over the ale joust,
And donge, when it commes,
In the ale tunnes.
Then Elynour taketh
The mashe bolle, and shaketh
The hennes donge away
And skommeth it into a tray
Whereas the yeest is,
With her maungy fystis:
And somtyme she blennes
The donge of her hennes
And the ale together;
And sayeth, Gossyp, come hyther,
This ale shall be thycker.

Though it was written in the tradition of the Gluttony scenes from *Piers Plowman*, and long remained in popular demand, it contributed largely to Skelton's later reputation as a "beastly" poet.

The years 1521–22 produced his three major political and clerical satires, *Speke, Parrot* (1521), *Colin Clout* (1522), and *Why Come Ye Nat to Court?* (1522). They are all poems of admonition to the king, directed against abuses in the church and the mounting power of Wolsey. In them Skelton formulates the position of the conservative clergy. He attacks the New Learning, rightly seeing in it the seeds of what was to be the Reformation. Wolsey's Humanism was as much a menace as his ambition. The church must be its own reformer. *Speke, Parrot*, one of the most allusive poems in English, demanding a knowledge of the learning and temper of the time and even of the day-by-day movement of events, returned to the medieval rime royal. *Colin Clout* and *Why Come Ye Nat to Court?*, in contrast, are directed toward their targets in vituperative Skeltonics, with precision of attack and deadly linguistic control.

Wolsey, however, was too strong an opponent. What reconciliation took place can only be a matter of inference. All of Skelton's major poems written later bear elaborate dedications to Wolsey. In his remaining years Skelton turned to other themes. It is significant that his next poem, the *Garlande of Laurell* (1523), is an elaborate *apologia pro vita sua*. Written while he was the honoured guest of the ladies of the Howard family, it contains (as a compliment to them) a group of lyrics Elizabethan in grace and felicity. The main theme of the poem (in rime royal) stems from Chaucerian dream allegory and *The Hous of Fame*. Dame Pallas and the Queen of Fame debate his entry to the Court of Fame, and Skelton stoutly defends his claim, listing his works, to hear in the end the assembled poets of antiquity and his English predecessors, Chaucer, Lydgate, and Gower, declare that he has triumphed. It is egotistical, jaunty, and completely successful.

His remaining poems, in Skeltonics, return to public issues. *The Duke of Albany* (1523) is an attack on the French and the Scots; *A Replycacion agaynst Certayne Yong Scolers* (1528), on Lutheran heresies within the church. In this latter work, the contrast between the sophisticated aureate prose of the preamble and the hard-hitting colloquial language of the Skeltonics is a reminder of Skelton's skill in Renaissance decorum at different levels.

Reputation.—Skelton fell rapidly out of fashion in the 16th century. His combination of religious orthodoxy in thought and

radical originality in presentation offended a predominantly Protestant England that looked to the Italy of the high Renaissance for its literary models. His use of colloquial speech-rhythm, with its echoes of Anglo-Saxon and alliterative Middle English verse, found no response among poets who preferred the sonnet and the canzone, and the "drumming decasyllabon." The emergence of the buffoon of the legend completed his eclipse as a poet who merited serious attention. Poets of the 20th century, reintroduced to speech-rhythm in verse by Gerald Manley Hopkins, have found in Skelton a source of new techniques. W. H. Auden and Robert Graves have both acknowledged their debt. Graves wrote a poem on him in Skeltonics, and has even claimed Skelton as "one of the three or four outstanding English poets."

Modern study of Skelton began with Alexander Dyce's edition in 1843. A group of studies by German scholars appeared toward the end of the 19th and in the early 20th century. Serious study began in England and the U.S. in the 1930s, and it is to a small group of scholars of that period that more precise knowledge of him is due. For a poet so original and so intensely personal as Skelton, much of whose poetry was written for a specific occasion, good critical work has had to wait till biographical facts and a firm chronology of the poems and the occasion of each were established, and is still hampered by lack of a full modern edition.

Bibliography.—*Bibliographies and Editions:* There are bibliographies, full up to dates of publication, in the books by W. Nelson, I. A. Gordon, and M. Pollet; and an excellent select bibliography in P. Green's (see *Biography and Criticism* below). The best edition of the poems, although inevitably dated, is still that by A. Dyce, 2 vol. (1843; U.S. reprints, 1855, 1856, 1887). *The Complete Poems*, ed. by P. Henderson (1931; 3rd ed., 1959), has a modernized text. There is a useful volume of selections, ed. by V. de Sola Pinto (1950). *Magnyfycence* was ed. by R. L. Ramsay for the Early English Text Society (1908; reprinted 1958). The prose works were first published as follows: *Speculum Principis*, ed. by F. M. Salter, in *Speculum*, vol. 9 (1934); *The Bibliotheca Historica of Diodorus Siculus*, ed. by F. M. Salter and H. L. R. Edwards, for the Early English Text Society (1956–57).

Biography and Criticism: F. Brie, "Skelton-Studien," in *Englische Studien*, vol. 37 (1907); W. Nelson, *John Skelton, Laureate* (1939); I. A. Gordon, *John Skelton, Poet Laureate* (1943); H. L. R. Edwards, *Skelton: the Life and Times of an Early Tudor Poet* (1949); M. Pollet, *John Skelton* (1962). Useful critical studies include W. H. Auden, "John Skelton," in *The Great Tudors*, ed. by K. Garvin (1935); E. M. Forster, in *Two Cheers for Democracy* (1951); J. Holloway, in *The Charted Mirror* (1960); P. Green, *John Skelton* (1960); A. R. Heiserman, *Skelton and Satire* (1961). (I. A. G.)

SKEPTICISM. Extreme skeptics deny that the human mind can attain knowledge. Total skeptics extend this denial to all kinds of claims to knowledge. But even the original Greek school of skeptics included few, if any, who were not partial or moderate: the former allowed that certain kinds of claims to knowledge were valid; the latter refrained from dogmatic denials of the possibility of knowledge and merely advised suspense of judgment. This restraint was more in harmony with the etymology of the word "skeptic," which is derived from the Greek word *skeptesthai*, "to examine." Dogmatic denials of the possibility of knowledge are always difficult to substantiate, and sometimes they seem to imply knowledge of the existence of the very things which are said to be unknowable.

Differences within the Greek school of professed skeptics have caused uncertainty about the classification of philosophers outside the school. Evidently a skeptic need not be dogmatic. But if a philosopher shows moderate skepticism it may not be a systematic doctrine, but perhaps only an attitude of mind. It may even be unconscious, and possibly the philosopher himself would repudiate the suggestion that he was a skeptic. For if partial skepticism is allowed it is by no means clear what kind of claims to knowledge must be admitted by everyone who is not a skeptic. Consequently the title "skeptic" has no agreed application, and its use reveals as much about the person who applies it as about the person to whom it is applied. For instance, skepticism about ordinary claims to knowledge is quite a different thing from skepticism about the claims of speculative philosophers, so that ordinary people and speculative philosophers are likely to disagree in their diagnoses of skepticism. Also, the same people who apply the word pejoratively to the rejection of their own claims to knowledge at other times may use it as a term of praise to point the contrast with credulity or superstition. However, most systematic skeptics, who stand at the centre of these extensions of their title, do have one tendency in common: they are reluctant to allow claims to knowledge about anything beyond the claimant's own immediate reactions; and consequently systematic skepticism has often been closely associated with some radical form of empiricism.

Greek skepticism passed through three stages. The school was founded by Pyrrho toward the end of the 4th century B.C. Next, in the 3rd and 2nd centuries, its ideas were absorbed, extended and modified by the philosophers of the Middle Academy and of the New Academy. Finally, it was revived as an independent school by Aenesidemus in the 1st century B.C. and carried on by Menodotus, Sextus Empiricus and others in the next two centuries.

Pyrrho's chief interest was ethics. He taught that, since knowledge is unattainable, the only way to achieve happiness is to practise suspense of judgment. He appears to have formulated this moral precept without any reservations. So he was neither a total nor an extreme skeptic. Perhaps it was the definiteness and simplicity of his moral teaching which enabled his follower Timon to claim that his philosophy did not conflict with common sense. Pyrrho's skepticism was directed chiefly against the dogmatic speculative theories on which the Epicureans and Stoics based their moral doctrines. However, skeptics who begin by attacking the recondite theories of philosophers often end by colliding with common sense, and Pyrrho's skepticism was not confined to philosophers' claims to knowledge.

The skeptical teaching of Pyrrho's school was taken over by Arcesilaus, the founder of the Middle Academy, and worked out in a more systematic way. This development was continued by Carneades, who founded the New Academy. Both were interested in epistemology for its own sake, unlike Pyrrho, who took it up because of its bearing on ethics. They produced a sustained and thorough criticism of the theory of knowledge which had been elaborated by the Stoics. But their work was not entirely negative. For though Carneades denied the possibility of knowledge, he offered a substitute: he admitted that judgments may have different degrees of probability.

The new skeptical school founded by Aenesidemus owed much to the work of the Middle and New Academies. It was systematic and self-conscious and classified the arguments which it inherited under ten headings (*tropoi*). Aenesidemus also took over the criticism of the powers of reason, which had been begun by his predecessors, and carried it much further. This inevitably raised a methodological problem: if reason is unreliable, the philosophical arguments which support this conclusion are themselves unreliable. This difficulty was usually evaded by a simile: the skeptic's arguments would be compared, perhaps, to fire, which consumes both its fuel and itself. Such comparisons are hardly adequate to remove the difficulty; what was needed was some way of distinguishing, as Kant did, between legitimate and illegitimate uses of reason. But the lack of any such distinction did not halt the attack on reason. Deductive reasoning was declared invalid, and inductive reasoning was submitted to a criticism which on many points anticipated Hume's views on causation. The conclusions of inductive arguments were rejected if they could not in principle be checked by observation. Even those which merely moved from phenomena to phenomena were said to yield something less than certainty. But at this point skepticism was tempered by the school's interest in medicine. This they regarded not as a science but as an art (*techne*), based on repeated and careful observation of the phenomena, never claiming absolute certainty and never postulating unobservable causes. In an instructive passage Sextus commends the grammar which children learn but condemns abstruse theories about the nature of the letters and their origin. Evidently his views on empirical matters were practical, cautious and positivistic, but not obviously skeptical. However, some philosophers would detect skepticism even here, on the ground that inductive arguments involve more than Sextus allows.

Outside the school of professed skeptics the attribution of the title is highly debatable, except in the case of the Middle and New Academies, which stood consciously within the skeptical tradition. But when the historian of ideas considers philosophers outside this

continuous Greek tradition, it is as if he had moved out of harbour into the open sea. However, it is just this move which is most likely to lead to some understanding of the nature of skepticism.

Michel de Montaigne is often classified as a skeptic because, in his *Essais,* he discussed every question in a detached and critical way. He certainly was not an extreme skeptic. But almost all philosophers have something of Montaigne's spirit. So, if Montaigne counts as a moderate skeptic, as no doubt he should, few philosophers have entirely lacked moderate skepticism, even in the Middle Ages, which constituted in some ways the least skeptical of all periods in the history of thought.

However, the rather more extreme forms of skepticism are perhaps worth diagnosing. But here too a great range of variation is encountered. Skepticism about a particular human faculty can be used by two different philosophers to support two entirely different conclusions. This is not altogether surprising, since the same doubt can be associated and contrasted with different certitudes. Plato impugned the reliability of the senses and claimed that the intellect could apprehend a transcendent world of "forms." Sextus rejected all speculation about transcendent reality, took over the Greek corpus of arguments against the senses and accepted medicine as something less than science. Sextus' combination of skepticism about the senses with empiricism is not as inconsistent as it might appear to be. For it is possible to try to allow for sources of error in perception and so to claim that it provides an adequate basis for probable conclusions.

Even Berkeley (*Principles of Human Knowledge,* 1710), who maintained that perception yields information only about the sensations of the perceiver, sincerely believed that this did not make him a skeptic. In this he was not entirely unjustified. For, if sensations are the only direct objects of perception (which not everyone would admit), it is not clear how the existence of anything beyond them could be validly inferred. Moreover, Berkeley claimed that material objects were merely collections of sensations in the minds of human beings and God, and this theory might well seem to be less skeptical than any theory which treats sensations as clues to the existence and nature of objects which are never directly perceived.

Berkeley's investigation of perception raises two connected questions about the nature of skepticism. When a philosopher says, not that a certain kind of thing exists but is unknowable, but that it does not exist, is he a skeptic? If, for instance, God's existence is denied, there is no doubt that this is true skepticism. But if a philosopher can plausibly claim that ordinary empirical judgments, when they are correctly construed, do not commit the speaker to belief in the existence of a certain type of thing, then the denial that these things exist is not obviously skeptical. This raises the second question, which is a question about the relation between ordinary judgments and philosophical doctrines: how is it possible to decide whether a philosopher's account of what ordinary judgments imply is correct? Many would say that Berkeley does not give a correct account of what ordinary perceptual judgments imply. But it is not easy to adjudicate in cases like this, if only because ordinary people do not often consider such matters deeply. Yet, until this question is decided, it is impossible to say whether a philosophical doctrine like Berkeley's is skeptical or not; unless, of course, the analysis of ordinary judgments is abandoned and the question is decided by appeal to some speculative theory.

Skepticism about the powers of reason can also lead in diverse directions. It led Sextus to pare down all ambitious claims to knowledge, leaving only the probable results of strictly empirical inquiries, shorn of all theoretical superstructure. It took Pascal, in his *Pensées,* to an entirely different conclusion: the impotence of reason seemed to him to leave all science open to doubt and to show up by contrast the reliability of religious faith. The difference between the sciences which these two had in mind probably explains their divergent estimates of the bearing of skepticism about reason on the claims of scientists. Clinical medicine is largely concerned with symptoms, probabilities and happy diagnoses, whereas applied mathematics is rigorous and theoretical.

Hume, who was also a skeptic about the powers of reason, gave a much more subtle account of science (*Treatise of Human Nature,* 1739; and *Dialogues Concerning Natural Religion,* 1779). Like Sextus, he condemned all theories which postulate unobservable causes behind the phenomena. Like Sextus too, he believed that reason, working on the results of observation, could not possibly establish any contingent general statements. For reason can establish only a priori statements (on this point he was more liberal than Sextus). Contingent general statements are believed not on rational grounds but only because continued observation of a conjunction of events has produced a habit of expectation. Such expectations are based on feeling and not on reason, and no justification of feeling is possible. It is merely an ultimate fact that human beings have this feeling. So there are two central propositions in Hume's philosophy: matters of fact cannot be established purely by a priori reasoning; they can be established only in a precarious way by nonrational inference; or else, perhaps, by direct observation. But even direct observation was not left unscathed by Hume. By an elaborate argument he sought to prove that no rational account of perceptual judgments is possible, and here too he fell back on feeling. Human beings, he said, are so constituted that they must believe in the existence of material objects beyond their sensations even though they can give no rational account of this belief.

Hume's account of inference inevitably seems skeptical to speculative philosophers. For it confines a posteriori inference to phenomena, and it declares a priori inference incapable of yielding new factual conclusions. However, when it is judged at the bar of common sense, it is not so easy to see how it should fare. Hume himself often said that, judged by these standards, it was skeptical, but it is not clear that he was right. Admittedly his refusal to allow that a posteriori inference is rational conflicts with ordinary ideas and linguistic usage. But on the other hand ordinary people might well rest fairly content with his account of the evidence which supports such inferences. For contingent general statements are based ultimately on the observed conjunctions of events, and it is not obvious that they assert anything more than that these conjunctions have always held and will always hold. No doubt the theory needs qualifying and modifying in various ways if it is to fit the facts exactly. But it is doubtful if ordinary people would agree with the much larger complaint of Hume's philosophical critics, that his theory altogether fails to account for the necessity of contingent general statements. However, Hume's theory of inference, like Berkeley's theory of perception, goes far beyond the point to which ordinary people carry the analysis of their judgments. Consequently it is not easy to estimate their reactions to the theory, or, in particular, whether they would call it skeptical.

However, it is possible to detect a pattern in the development of such difficult cases and so to understand why they are difficult. The ordinary person makes judgments which he does not analyze. Some philosophers hold that these judgments commit him to hypotheses which transcend the available evidence. Then other philosophers, allegedly skeptics, react by saying that they commit him to nothing beyond the bare phenomena. The controversy proceeds by a kind of diastole and systole. Perhaps neither the expanding nor the reducing theories are correct, but rather something intermediate. In any case this pattern of philosophical controversy explains why it is so difficult to decide whether reducing theories like Hume's are, from the point of view of the ordinary person, skeptical.

Kant thought that Hume's theory was skeptical, and he tried, in his *Critique of Pure Reason,* to work out a theory of knowledge which would be acceptable to an empiricist and yet free from what he thought was skepticism. At the same time he wished to curtail the speculative flights of reason. What he had in mind was not so much the speculative hypotheses which philosophers sometimes reach in the course of analyzing ordinary judgments, but rather the elaborate deductive systems of the metaphysicians of the 17th century. He called his own philosophy critical, to distinguish it both from what he regarded as skepticism and from what he regarded as dogmatism. This word "critical" is close to the etymology of the word "skeptic," in fact closer than the popular connotation of skeptic. The whole field would be easier to survey if Kant's distinction between criticism and skepticism had always been ob-

served. As it is, the word "skeptic" usually covers both. However, even Kant's use of the word is not consistent. It can mean one who denies that something exists, or one who allows that it exists but maintains that its nature cannot be known, or one who claims that a whole area of so-called knowledge is vitiated by inconsistencies. Hume's theory of perception belongs to this third type.

Kant believed that human reason imposes certain categories on the raw material of experience which somehow comes from things in themselves. Phenomena are the result of this operation. Causality is one of the categories. So, if a philosopher doubted the validity of causal inferences, as Kant thought that Hume did, he could be answered by the contention that causality is already an ingredient in phenomena as we know them. This illustrates the positive part of Kant's philosophy: reason is rehabilitated in the sphere of phenomena. Kant's negative teaching was that reason cannot extend its operation beyond phenomena. For instance, any attempt to use the category of causality to reach some speculative conclusion would inevitably lead to contradictions; the apparatus of reason, having no material to work on, would cease to function properly.

In spite of Kant's intention there is an element of skepticism in his system. Ostensibly it is critical and only seeks the limits of the powers of reason. But it gives these limits in terms which imply awareness of the existence of things in themselves. It is hard to see how Kant can consistently allow this awareness of the existence of things in themselves. However, since he does allow it and since at the same time he denies the possibility of any knowledge of the nature of things in themselves, he is on this point a skeptic. On the other hand, he was not in the least skeptical about the possibility of knowledge of what he called phenomena.

Kant used the term "phenomenon" in a neutral way that did not imply an unfavourable contrast with things in themselves. Most of his idealist followers thought that this was an inconsistency and rejected the hypothesis of things in themselves. Some rejected even the claim that phenomena are knowable, supporting this rejection with arguments very like those which Kant had used to show that things in themselves are unknowable. They tried to establish that there are latent contradictions even in quite ordinary claims to knowledge. This kind of dialectical argument, which they inherited from Kant and adapted to a more subversive use, had existed in antiquity and had often been used to undermine the beliefs of ordinary people in just this way. Hume's treatment of perception is an example of this kind of reasoning, but it is as old as Zeno. It produces a special kind of skepticism, which is conspicuous in the writings of 19th-century idealists and was taken to the extreme limit by F. H. Bradley (*Appearance and Reality*, 1893), who found that all claims to knowledge are self-contradictory.

This kind of skeptic does not deny that things of a certain kind can be known to exist; nor does he admit that they exist but deny that their nature can be known: instead he maintains that parts, or perhaps even the whole, of what is alleged to be knowledge cannot be knowledge since it contains hidden contradictions. The first two of these three kinds of philosophical skepticism rely on analogies with ordinary situations in which people refrain from claims to knowledge, perhaps misleading analogies, but at least intelligible ones. This third kind of skepticism is more difficult to understand. A pragmatist would ask how anything which works so well as science could possibly be self-contradictory. An idealist such as Bradley would reply by introducing the doctrine of degrees of reality. What the scientist discovers cannot be perfectly real, since it contains contradictions, but nevertheless it is not sheer illusion, since successes can be achieved even on lower levels of reality. But the scientist must appreciate that he is on a lower level and must not make any claims about ultimate reality, which is the domain of the metaphysician. This kind of system is, from the point of view of the ordinary person, skeptical, and skeptical in a very peculiar way. But the philosophers who build such systems would say that they give every claim to knowledge its due and would confine the title "skeptic" to those who reject transcendent reality.

These speculative adventures inevitably produced reactions in the 19th century. Both pragmatists and positivists defended science and common sense against these dialectical attacks and professed themselves at least agnostic about transcendent reality. However, their defense of science was often associated with very reductive theories, similar to Berkeley's and Hume's, and this controversy provides yet another example of the perennial pattern of extreme contraction alternating with extreme expansion. Also agnosticism about transcendent reality is a difficult position to maintain because, if it is really true that ordinary judgments commit people to belief in transcendent reality, agnosticism about transcendent reality is strictly inconsistent with the claim to understand and accept ordinary judgments.

These two weaknesses in the empiricist reaction were not irremediable. The pragmatists investigated the meaning of scientific statements in a sympathetic way and claimed that they contained no contradictions and did not point to any transcendent reality. They also investigated the meaning of other kinds of empirical statements and tried to give a comprehensive criterion of meaningfulness. Their work was carried on by the logico-analytic school in the 20th century; and, though it sometimes produced reductive theories, this did not always happen. When it did happen, it was not because there is any good reason why theories about the meaning of empirical statements should be reductive, but rather because the logico-analytic school inherited the tradition of Berkeley and Hume and because in any case extreme reaction is natural.

G. E. Moore, Bertrand Russell and Ludwig Wittgenstein were the three most important philosophers of this school. Its attitude to speculative philosophy was critical rather than skeptical because when its members rejected speculative theses, it was on the ground not that they were false but that they were meaningless, or at least involved misuse of language. However, if the idealist attack on empirical statements is to be classified as a kind of skepticism, then it might be correct to call the logico-analytic philosophers skeptics because of their attack on speculative philosophy. For, though the objects of the two attacks were different, their methods, the detection of contradictions and the diagnosis of meaninglessness, were very similar. But, if the word "skeptic" is used pejoratively, it is important to remember that there is a certain presumption in favour of common sense. The logico-analytic school did not merely rest on this presumption: it tried to show that both the apparent contradictions in ordinary empirical statements and the apparent meaningfulness of speculative theses are the results of illusions; *cf.* particularly Moore's "Defence of Common Sense," in *Contemporary British Philosophy*, 2nd series (1925); and Russell's *Mysticism and Logic* (1918).

Two different tendencies can be detected in the writers of this school. Some of its adherents tried to give a single criterion of meaningfulness which would cover all ordinary statements and exclude those of speculative philosophers. In this way they hoped to evade the difficulty which Kant had failed to evade, the difficulty of limiting knowledge without implying some awareness of what lies beyond the limit. For if statements about what lies beyond the limit could be shown to be meaningless, the inconsistency would be avoided. This systematic attempt to delimit the sphere of meaning was made in Wittgenstein's *Tractatus Logico-Philosophicus* (1921), which was closely related to Russell's work in logic. Its weakness was that it set up scientific statements as the type to which all meaningful statements must conform. This places it in the tradition of the 19th-century pragmatists and positivists. In fact some of the philosophers who tried to work out these ideas of Wittgenstein in more detail called themselves logical positivists. The other tendency within the school was a reaction against any attempt to give a systematic account of meaning. Every type of ordinary statement should be examined separately and judged by its own standards. This tendency begins in the writings of G. E. Moore. It also appears in the later writings of Wittgenstein, who added the corollary that, if speculative philosophers are wrong in thinking that their statements mean something, this too should be established by a detailed examination of each individual case. This tendency, judged by ordinary standards, was obviously not skeptical; it was a vindication of common sense in which many speculative philosophers would detect credulity.

There are many reasons why the diagnosis of philosophical skepticism will always be debatable. Greek skepticism had many fac-

ets, and outside the Greek school different philosophers show different combinations of these facets. However, when the word "skeptic" is used about the rejection of particular claims to knowledge on ordinary grounds the difficulties are less formidable. In such cases both the claimant and the rejector will usually be appealing to similar standards: they will differ in their application of these standards; and they may also differ about the force of the word "skeptic," whether it is pejorative, commendatory or neutral. These complications need to be unraveled, but the task of unraveling them is comparatively easy. But when philosophers question whole departments of knowledge, they are really questioning the standards which are ordinarily taken to be reliable within these departments. At the same time they frequently offer different, stricter standards and sometimes make strange new claims to knowledge of their own. This enormously widens the scope of the debate and makes it very hard to decide which philosophers are skeptics, which dogmatists and which merely critical. It might appear that this question could be safely settled only by a philosopher who adopted the standpoint of common sense. But even here the difficulties do not end. In fact the greatest difficulty of all is to understand the intricate relations between ordinary beliefs and philosophical doctrines. For few philosophers entirely abandon ordinary beliefs. Even those who do not analyze them sympathetically usually recast them and let them stand in an altered form. And there is no simple way of deciding when justice has been done.

For theological skepticism *see* AGNOSTICISM.

SKIING, a way of moving over snow wearing a pair of long flat runners called skis attached to the shoes or boots. It is practised for recreational, competitive, or utilitarian purposes. On the level or on slight grades, the skier uses a gliding gait; downhill he slides effortlessly over the snow, turning to avoid obstacles, to slacken speed, or to change direction; special steps are used in climbing steeper slopes. Ski jumping is usually performed on artificial inclines of varying size especially designed for the sport.

Skis were first used for utilitarian purposes, for transportation, hunting, and in warfare, as they are still. Recreational skiing was a natural outgrowth of such uses. In the Americas and the Alps the sport developed chiefly as downhill skiing.

At first, only the mountain railways and aerial cable cars, or funiculars, of the Alps were available for the uphill transportation of skiers. In the early 1930s, many new devices were designed and built for this purpose, including chair lifts, numerous types of bar lifts such as the T-bar tramway, gondola lifts, and in the U.S. and Canada, rope tows. These greatly promoted the popularity of skiing, for they made possible four or five times as much skiing in a day as when the skier had to climb uphill; and they made the sport more enjoyable for all participants. In the Scandinavian countries and Eastern Europe touring and cross-country skiing developed as the more popular sports.

Competitive skiing comprises the Nordic (or classic) events—cross-country racing and jumping; and the Alpine (or downhill) events—downhill (or straight) racing, slalom (zigzag downhill) racing, and giant slalom (see *Competitive Skiing*, below).

Following a description of the equipment used in skiing, this article discusses the history of skiing and the development of modern Alpine skiing, competitive skiing, and the organization of the sport; selected skiing terms are given in the glossary. For Olympic championships *see* OLYMPIC GAMES.

EQUIPMENT

The Ski.—The three chief types of skis, downhill, jumping, and cross-country, have certain characteristics in common. They are pointed, turned up, and usually slightly wider at the front (the tips or shovel) and are squared at the rear (or heel). They are thickest in the midsection, under the foot, thinnest just before the ends, and are built with a slight arch, or camber, so as to distribute the skier's weight evenly along the length and thus

impress a maximum running surface, with maximum edge-length, on the snow. Over the years skis have been refined in their shape and camber and in precision of stiffness.

Skis vary in length, the downhill ski for the average adult man being about 7 ft. (213 cm.) long, although much shorter skis, slower but more maneuverable, have enjoyed some vogue. They were formerly fashioned from one piece of wood, usually hickory, but from the 1930s laminated constructions also were used. After 1950, plastic running surfaces were introduced to increase speed and durability, and skis of metal, usually with a wood or plastic core, became increasingly popular. The downhill ski, which is about 3 in. (7.6 cm.) in width, typically has a shallow groove running longitudinally along the centre of the bottom (or sole); this imparts directional stability. In addition, skis have sharp edges of steel along the undersurface, in order to bite into hard snow or ice. Jumping skis are longer (about 8 ft. [244 cm.]), wider, thicker, and heavier and ordinarily have three grooves in the bottom. They have no steel edges. Cross-country skis are narrower and lighter in weight than downhill skis and often are laminated. They have one groove but no metal edges.

Other Equipment.—For downhill skiing, the skier wears close-fitting, heavy leather boots with flat and stiff soles in order to exercise precise control over the skis. The boots are firmly attached to the skis by bindings, often with safety or release bindings, developed to free the skier's foot in case of falls. For jumping and cross-country a lighter and more flexible boot is used, with a binding which allows the heel to be raised.

For downhill skiing a light pole, or stick, of metal or bamboo, about four feet long, is carried in each hand. For cross-country skiing the pole varies in length. These aid the skier in pushing himself along on the level, and in climbing. They also are used in maintaining balance when running downhill and to assist in turning. Each stick has a wrist strap at the top and a ring, or wheel, near the bottom, which prevents the point from sinking too deeply into the snow. Various waxes, depending on temperature and snow conditions, are used on the bottoms of skis to prevent snow from sticking to them and to reduce friction. To aid in climbing, strips of sealskin or plush are sometimes strapped to the bottoms of the skis to grip the snow.

The refinements in ski equipment after World War II were accompanied by a great increase in the proficiency of the average recreational or competitive skier. As the parallel (skidded) technique supplanted the earlier stemmed (steered) turns, speed and maneuverability were greatly increased. (R. Po.)

HISTORY

The oldest ski that has been found, in a bog at Hoting in Sweden, is believed to be at least 4,500 years old, and the oldest pictorial representation dates from about 2000 B.C. Some sort of skis or ski-like snowshoes were probably used in many regions where men found them useful to travel or hunt in snow-covered country. Procopius, the Byzantine historian, *c.* A.D. 550, mentions "Skridfinns," that is, gliding Finns, in apparent contrast to the Finns who did not glide.

Military Skiing.—Skis were early used for military purposes; according to Norwegian historians, the Vikings used skis on raids in Norway in the 10th and 11th centuries. One record shows that in 1200 King Sverre of Norway sent out men on skis to reconnoitre before battle. In the 15th, 16th, and 17th centuries skis were used in warfare in Norway, and in Russia, Sweden, Finland, and Poland. Subsequently, skis have been used in warfare in many places, as along the Austrian-Italian front running through the Alps in World War I. During the Russian invasion of Finland in 1939–40 much use was made of ski-equipped troops.

Ski Mountaineering.—Skis have been used in mountaineering since the 1880s, in Norway, and in the Alps since the mid-1890s. The first important expedition in central Europe was the incomplete traverse of the main massif of the Bernese Oberland by a German party, including W. Paulcke. From the beginning of the 20th century the French, Italians, and British also took part.

Development of Skiing as a Sport.—There are records of military ski competitions in Norway in 1767 and civilian competitions at Tromsö in 1843. But skiing as a competitive sport really began about 1860 when Sondre Nordheim, from Morgedal in Telemark, invented bindings around the heels fastening the boots to the skis, thus making jumps and turns possible. Competitive skiing also started in California in the 1860s, but because there the skiers had only toestrap bindings it was impossible for them to make turns and they ran only straight downhill courses.

The first big ski contest was held at Huseby Hill, Oslo, in 1879, with 10,000 spectators in the presence of the king. This contest, held yearly, was moved to the Holmenkoll Hill in 1892. In 1888 Arctic explorer Fridtjof Nansen led a party across Greenland on skis, dragging sledges. His book, *Paa Ski Over Grönland*, was translated into English, German, and French in 1891 and exerted a great influence on the development of skiing in central Europe, particularly in the Alps and the Black Forest of Germany. The first competitions were in jumping and slalom without gates—slalom gates were invented by the British in 1922.

As the sport spread, both proficiency and equipment developed rapidly. Because the terrain in the Alps was steeper and more difficult, a new skiing technique was needed. The erect, Norwegian Telemark and Christiania style was gradually supplanted by an Alpine way of skiing downhill and turning. (J. VA.)

MODERN, ALPINE SKIING

As Alpine skiing developed, the Nordic manner of skiing was modified and eventually basically changed to allow the skier to cope with the long, steep runs in the high mountains, and the obstruction-filled glaciers and forested hillsides. Outgrowths of these changes were the ski school where the new method was taught, and the downhill and slalom competitions that tested the relevant skills.

A pioneer in adapting skiing technique and ski bindings to the requirements of Alpine terrain was Mathias Zdarsky of Austria. He was probably the first regular ski teacher in that country, having registered over 1,000 pupils of his "Lilienfeld technique" as early as 1904. Later he extended his courses to Germany and Switzerland.

Viktor Sohm of Bregenz, another Austrian of the 1890s who conducted courses, adhered to the Norwegian style. A professional ski teacher was first heard of in 1906, Reinhard Spielman, who taught on the Semmering, near Vienna.

Col. Georg Bilgeri of Austria, W. Paulcke and Henry Hoek of Germany, Col. Christopher Islin of Switzerland, and Sir Arnold Lunn and Vivien Caulfeild of Great Britain should also be mentioned as pioneering contributors to modern skiing.

Ski Schools.—To Hannes Schneider is attributed the credit for laying the foundation both of the modern ski technique and the thoroughly systematized ski school. He started teaching in St. Anton in Austria in 1907, developing the crouched position and the stem Christiania, as well as the position of "vorlage," or putting the weight forward. He taught in a methodical progression from snowplow, through snowplow turn, stem turn, and stem Christiania, to parallel swing initiated with only a slight, quick stem. He soon found graded classes and additional instructors necessary. During World War I, he further developed his methods while training Austrian mountain troops.

Since World War I instruction has been systematized, and, as more efficient techniques have been developed, largely in competition, these have been taught. Concurrently, more and more people attended the ski schools, and the sport spread to all parts of the world where there was snow, for the satisfaction of advancing in skill, and the ability to ski faster and in control add greatly to the pleasure derived. The first ski teachers examination was held in 1925 in Austria. This has become increasingly exacting over the years, and other countries, including Switzerland, France, Italy, Germany, and the United States, have adopted similar tests, with certification considered a mark of professional competence. By 1930 there were several well-organized ski schools in Switzerland, and shortly thereafter courses for teachers were instituted. Under the leadership of Christian Rubi, the Swiss Ski Schools promoted a uniform method of instruction at the various important resorts.

While Schneider's Arlberg ski school put great emphasis on the stem and stem turns as the basis of its technique, the Swiss avoided what they considered excessive attention to these positions, and later the French schools, too, took a more direct route to "parallel" skiing. Émile Allais and Paul Gignoux brought the French theories to the forefront when they declared war on the basic stem and rotation. Ahead of their time were Eugen Matthias, physiologist of the University of Munich, and Giovanni Testa, head of the ski school in St. Moritz, who first taught the reverse (or inside) shoulder technique and turning with knees together in the mid-1930s. Their book, *Natürliches Skilaufen* (1936), attracted considerable attention, but was not at the time recognized as prophetic of what was to come.

Since World War II, the techniques taught and the sequence of instruction in the ski schools of the various countries have tended to become more similar. In particular, less emphasis is placed on a thorough and almost exclusive grounding in the stemmed turns. Instead, a parallel position of the skis is inculcated; and to make this habitual, early stress is placed on sideslipping, traversing, edge control and straight running of slopes. The chief differences are between the Austrian system of rhythmic short-swinging (*wedeln*) turns, distinguished by counterrotation and leading with the inside shoulder in turning; and the French turning style of *projection circulaire*, in which the shoulders are kept almost square to the direction of movement during a turn.

Among the important factors leading to these developments were the introduction of the steel edge, in the 1930s, and the great increase in the number of ski lifts, beginning in the late 1940s. The former formed the basis for parallel, narrow-tracked, and precise running and turning; the latter—which greatly increased the numbers of skiers and multiplied the number of runs each one could make downhill, with the consequence that nearly all skiing must be done on well-broken and well-worn trails rather than on virgin snow—made necessary the development of sideslipping and short-swinging (short-turning) techniques.

The Basic Movements.—Brief identifications of the basic skiing movements referred to above and commonly taught in most schools follow. The best way to learn these movements is with a certified instructor.

Stemmed Turns.—Formerly the focus of instruction, these are based on placing one or both skis at an angle to the direction of movement. The chief turning force is shifting of weight. The snow-plow turn is made from a snowplow, or double stem (skis in a "V"), position by shifting the weight to one ski and exerting outward-turning pressure with that heel to make a steered turn.

The stem turn is made from the traversing position (with skis parallel) by stemming (angling out) the upper ski and turning as in the snowplow. The stem Christiania is similar except for the manner of shifting the weight and moving the body, while the Christiania is a swing from a slight initial stem that continues across the fall-line. The pure Christiania is a series of sweeping swings back and forth across the fall-line.

Sideslipping.—This maneuver became necessary to avoid ruts and bumps as hard-packed trails became common, and as it also inculcates the parallel ski position and teaches edge control, has become the basis of modern instruction. The skis are skidded sideways by flattening the skis to disengage the edges and pushing the heels downhill and the skis out from under the body.

Traversing.—This is running downhill diagonally across the fall-line with the skis parallel, and close together for greatest control.

Straight Running.—In the downhill position for running in the fall-line, the skis are flat, parallel, close together, and equally weighted. The goal is a graceful, relaxed position, slightly forward-leaning (vorlage), with smooth movements to adjust the skier's centre of gravity to changing conditions of snow and slope.

Short-Swinging and Wedeln.—These consist of consecutive short, parallel swings across the fall-line, one after the other. In the short swing there is alternating pole planting; in wedeln there is practically no edging. The legs and hips are used a great deal in the sequence of swing and counterswing.

COMPETITIVE AND RECREATIONAL SKIERS

Three Olympic gold medal winners: (top) Finnish ski-jumper Veikko Kankkonen leans far forward to reduce wind resistance and gain lift; (centre) Marielle Goitschel of France negotiates gates during woman's giant slalom race; (left) Austrian skier Egon Zimmermann leaps during men's downhill race; (right) recreational skiers on a slope at St. Moritz, Switz.

(TOP) CENTRAL PRESS PHOTOS (BOTTOM LEFT) PICTORIAL PARADE, (RIGHT) HANS STEINER—PHOTO RESEARCHERS, INC.

Safety and Courtesy.—With large numbers of new skiers appearing on the slopes each year, a code of safety and courtesy has been suggested for the protection both of the skier himself and of the other persons on the hill.

"Ski in Control"—skiing in such a way that the skier at all times can turn or stop—is the basic objective of the following "rules of the road" that are followed by most experienced skiers.

1. Skiers approaching each other on opposite traverses pass to the right.
2. An overtaking skier warns the skier ahead with the cry, "On your right," or "On your left." The call, "Track!" is a warning that a fast skier is coming down a trail or course, or a loose ski or other object is sliding downhill.
3. An uphill skier is responsible for avoiding a skier below him.
4. A skier entering a trail yields right-of-way to skiers already on the trail.
5. A moving skier avoids a stationary skier, and passes at an ample distance.
6. A skier does not stop at any spot that will obstruct a trail, or impede the passage of following skiers, or where he is not plainly visible from a safe distance above. A skier who has fallen in such a spot moves to a safer location as soon as possible.

Ski patrols composed of volunteers or professionals who are specially trained for first aid and rescue work are available at all times in most ski areas to assist skiers who are lost, ill, or injured, or otherwise are in need of help.

COMPETITIVE SKIING

Downhill races are run on defined courses of a length, steepness, and difficulty appropriate to the skill and endurance of the entrants. For men's Olympic and world's championship events, a vertical descent of at least 2,625 ft. (800 m.) is prescribed, with sufficient steep and difficult terrain. Such courses may be between 1½ and 3 mi. long (2.4 and 5 km.), although some races are considerably longer. Average speed of the winners is usually between 40 and 50 mph (64 and 80 km.ph). Speeds of more than 100 mph (161 km.ph) have been recorded on special short courses.

For a slalom race the course is defined by gates consisting of pairs of poles with flags, between which the runner must pass. The course is carefully set so as to test the skill and judgment of the competitor. For Olympic and world championship events the men's course must have a vertical drop between 650 and 975 ft. (198 and 297 m.) and for other international races between 390 and 650 ft. (119 and 198 m.). Fifty to seventy-five gates are required for men, forty to fifty-five for women. For less skilled groups, courses are shorter and less difficult. The Arlberg-Kan-

dahar race rotates between Mürren, Switz.; St. Anton, Aus.; Chamonix, France; Sestriere, Italy; and Garmisch-Partenkirchen, Ger., and is the oldest open international event decided on the results of a downhill and a slalom, having been first run in 1928.

The giant slalom has characteristics of both the downhill and the slalom. The gates are set wider and farther apart, the length of the course approaches that of the downhill and the average speeds achieved are between those of the two other Alpine events. Because of the persistent efforts of Sir Arnold Lunn, who devised the modern slalom race, the International Ski Federation recognized downhill racing in 1930, and the first downhill and slalom world's championships were held in Mürren in 1931. The best Alpine competitors have come from Austria, France, and the other western European countries.

Cross-country races are held over rolling terrain. The standard distances in international competition are 15, 30, and 50 km. for men, and 10 km. for women, although the Vasa race in Sweden is 56 mi. long. In the relay race four men each run a 10 km. course, or three women a 5 km. course.

Jumping competitions are held on carefully graded and prepared hills, classed according to size as 100-m., 80-m., 70-m., etc. The approach, or inrun, often starts on a scaffold, or tower; down it the jumper in a crouched position accumulates speed until he reaches the takeoff, where he leaps outward, upward, and forward. The best competitors lean far over toward the points of their skis in order to minimize wind resistance and to get an aerodynamic lifting effect to increase the length of their jump. The landing is made on the steep landing hill in a more upright position with the shock of contact taken up by the knees. After the slope levels off, the jumper stops by turning on the outrun. The performance is decided half by the distance covered and half on form, as marked by the judges, on the basis of style marks.

The best jumpers and cross-country runners have come from the Scandinavian countries, Finland, and eastern Europe.

A combination of the results of the downhill and slalom is called the Alpine combined event, and the jump and cross-country together are called the Nordic combined. The biathlon, an Olympic Games event combining cross-country racing and rifle shooting, is a modern offshoot of Nordic and military skiing. Skijoring, in which the skier is pulled by a horse, car, or plane, is little practised.

ORGANIZATION OF THE SPORT

The International Ski Federation (Fédération Internationale de Ski, or FIS) was founded, and the first winter Olympic games were held, in Chamonix in 1924, but with Nordic ski events only. The Alpine events were included for the first time in 1936, at Garmisch-Partenkirchen in Germany.

The world's first ski club was the Trysil, in Norway, formed in 1861. The first in the United States was organized at Berlin, N.H., in 1872. The Ski Club of Great Britain, founded in 1903, was the sport's first national administrative body. It was superseded by the National Ski Federation of Great Britain (1964). The first intercollegiate ski meet, between McGill, Dartmouth, and Montreal, was held in Quebec, at Shawbridge, in 1914.

The basic skiing organization is the local club, which is composed of individuals. In the United States, most clubs are members of one of the regional associations (or divisions) which compose the U.S. Ski Association, formerly the National Ski Association of America (1904) founded at Ishpeming, Mich. The latter, along with the national associations of the other skiing nations throughout the world, compose the FIS, which sets the rules for and sanctions international competitions in all forms of the sport, and engages in other coordinating activities.

GLOSSARY

Alpine (events, races).—Downhill and slalom competitions.

Arlberg strap.—A leather strap which is attached to the cable of a binding and passes over the instep and around the ankle (see *Safety Strap*).

Basket.—See *Ring*.

Bob-run.—A hard-surfaced channel that has been hollowed out by many skiers running in the same track.

Bow.—A forward inclination from the waist, as in bowing.

Brink.—Point or line at which a sharp increase of grade occurs.

Camber.—The arch of the ski, from front to rear.

Change edges.—Shift the lateral cant of the skis so that the previously disengaged edge, or edges, are weighted and canted.

Christiania.—A ski turn executed entirely, or largely, with skis parallel

Classic.—See *Nordic*.

Climbers.—Attachments to the bottoms of skis to facilitate climbing by preventing backsliding.

Comma.—Body position in traversing or turning in which the upper body is angled away from the slope and the knees, held together, are bent toward the slope.

Control gate.—A pair of flags on a downhill slalom course through which a racer must pass.

Corn snow.—Granular snow created by alternating thawing and freezing.

Cornice.—Overhanging drift of snow on the lee side of a ridge or summit.

Counterrotation.—Turning the body in the direction opposite to the direction of the turn.

Creepers.—See *Climbers*.

Critical point.—The place or line on the landing hill of a ski jump beyond which the gradient decreases and landings should not be made.

Double stem.—Position of the skis making an inverted "V," with tips together.

Dry course.—Ski instruction given indoors, or on ground without snow.

Edging.—Canting the ski so that one edge bears more weight than the other and thus "bites" the snow.

Egg Position.—Compact, crouching downhill running position with elbows close to body and hands together in front.

Fall-line.—Direction of steepest descent at any point.

FIS—Fédération Internationale de Ski, or International Ski Federation, governing body of the sport.

Flying mile (or kilometre).—A measured straight downhill course, often shorter than a mile or kilometre, on which speeds are timed.

Gate.—Two poles between which competitors must pass.

Geländesprung (Ger.).—A leap from a bump or brink, during which the knees are retracted.

Giant slalom.—A race between gates which are wider and further apart than in a slalom.

Godille (Fr.).—See *Wedeln*.

Grat (Ger.).—A ridge or col.

Hairpin.—A sharp turn in a slalom course forced by two gates

Heel-turning pressure (*Heel thrust*).—Force exerted in the horizontal plane by the heel pivoting on the ball of the foot.

Herringbone.—Method of climbing by alternately placing one ski above the other in a diagonal position, with the tips out.

Inrun.—The track from the top of a jumping hill to the takeoff.

Inside (ski, foot, hip, shoulder).—The one toward the inside of the turn.

Jump turn.—A turn executed while in motion by lifting the skis from the snow with the aid of one or both poles, and turning them in the air.

Kick turn.—A turn made from a stationary position by placing first one ski and then the other in the desired direction.

Knoll.—The part of a ski jump beyond the takeoff where the landing hill begins.

Landing hill.—That part of a ski jump where the landing should take place.

Lip.—The furthest edge of the takeoff of a jumping hill.

Long-thong (or *longlanière*).—A long strap for attaching the boot to the ski.

Mogl (or *mogul*).—A pronounced bump created by skiers wearing grooves in the snow.

Nordic (events).—Jumping and cross-country competitions.

Outside (ski, edge, foot, hip, shoulder).—The one toward the outside of the turn.

Outward lean.—Bending sideways from the waist toward the outside of the turn.

Piste (Fr.).—A prepared snow track for skiing.

Powder.—A light, dry, uncompacted snow.

Prejumping.—Making a jump just before a large bump or brink in order to clear it and land on its down side.

Ring (wheel, or basket).—Attachment to a ski pole just above its point to prevent its penetrating into the snow excessively.

Ruade (Fr.).—A turn made by lifting the heels of the skis clear of the snow.

Rücklage (Ger.).—Position with body back, weight on the heels, useful in skiing in deep powder snow.

Safety strap.—A small strap connecting ski to boot, to prevent the ski from running away if it comes loose.

Schuss.—A steep hill that can be run straight at high speed; running such a hill.

Schussboomer.—A person who skis out of control or at speeds beyond his ability.

Scissors.—Ski position with tips diverging, back ends together.

Sealskins.—Strips of sealskin attached to the bottom of skis to aid in climbing.

Seelos.—A famous slalom runner, after whom was named a com-

bination of three gates in a slalom course with the second gate between and at right angles to the first and third.

Shovel.—The upturn at the forward end of the ski.

Sideslip.—Sideways or diagonal sliding of the skis.

Sidestep.—Moving uphill by alternately placing the skis across the hill higher and parallel to each other.

Single stem.—Position with one ski at an angle to the other and to the direction of movement.

Sitzmark.—Depression in the snow made by a skier sitting down when falling.

Skating.—Moving forward on the level or a gentle slope by skating steps.

Skins.—See *Sealskins;* also applied to such devices made of plush, canvas, etc.

Slalom.—A race down a course controlled by flags.

Snowplow.—Descent in the fall-line in a double stem.

Spring snow.—Granular or corn snow (*q.v.*).

Stem.—A position of a ski or the skis divergent to the direction of movement.

Stembogen (Ger.).—A turn made by use of a stem.

Swing.—A turn made at high speed, largely with skis parallel.

Téléférique (Fr.).—A large car, usually suspended from a stationary track cable and pulled by a traction cable, for carrying passengers uphill.

Telemark.—A steered turn in which the outside ski is weighted and advanced about a half ski-length beyond the other.

Tempo.—A high speed turn made with skis parallel.

Tramway.—Any device other than a rope tow for hauling skiers uphill

Transition.—Area or line where the grade of a slope lessens or flattens out.

Traverse.—A course diagonally across and down a slope.

Trestle.—A girder structure for all or part of the inrun or landing hill of a ski jump.

Unweighting.—Removing the body weight from one or both skis.

Vorlage.—Position with body, knees and weight forward.

Wedeln.—Making a series of short connected parallel turns.

Wheel.—See *Ring.*

Windslab.—A crust formed on top of snow by wind action.

SKIKDA (formerly Philippeville), a town and Mediterranean seaport of northeastern Algeria, in the *département* of Constantine, lies on the Gulf of Stora, about 55 mi. (89 km.) NNE of Constantine by rail and road. Pop. (1960) 80,281. Formerly the population was predominantly European, partly of Italian and Maltese origin, but during the war that preceded and followed Algerian independence (1962) there was an influx of Muslim refugees and an exodus of Europeans. Founded by the French in 1838 to serve as the port of Constantine, Skikda is rectilinear in plan and occupies the site of ancient Rusicade, which was the port of Cirta, as Constantine was called until the 4th century. It lies near the mouth of the Safsaf River, escaping the humidity of the alluvial plain by its situation on a saddle between two hills. The road and railway to Constantine follow the course of the former Roman road. The Safsaf Valley is rich in vines, citrus fruit trees, and early vegetables; Skikda exports its products as well as those of the upper plains of the Constantine region (chiefly cereals, wool, and mutton), dates from the oases of the Biskra region, and iron pyrites from the surrounding district. It imports combustibles and construction materials, and also a variety of manufactures and sugar and coffee, which are redistributed through Constantine to the whole of eastern Algeria. There is considerable passenger traffic through the port, which, with the village of Stora, is a centre for sardine fishing and canning. (J.-J. Ds.)

SKIN, the covering, or integument, of an animal, as distinguished from the internal parts. In animals with backbones (vertebrates) the skin is complex in structure and is a vital organ in that some of its functions are essential for the maintenance of life. In all vertebrates the skin consists of two major layers. The richly cellular, relatively thin outer layer, derived from the embryonic ectoderm, is called the epidermis; the thicker and tougher inner part, of mesodermal origin, is largely composed of fibrous connective tissue and is called the dermis, cutis, or corium.

Skin in Lower Vertebrates.—Before considering the skin of man, the integuments of various classes of vertebrates will be surveyed in the order of their position on the evolutionary scale.

Cyclostomes.—In the lamprey the surface of the skin is smooth, with no scales. Gland cells producing slime are mixed with the epithelial cells, as in most aquatic vertebrates.

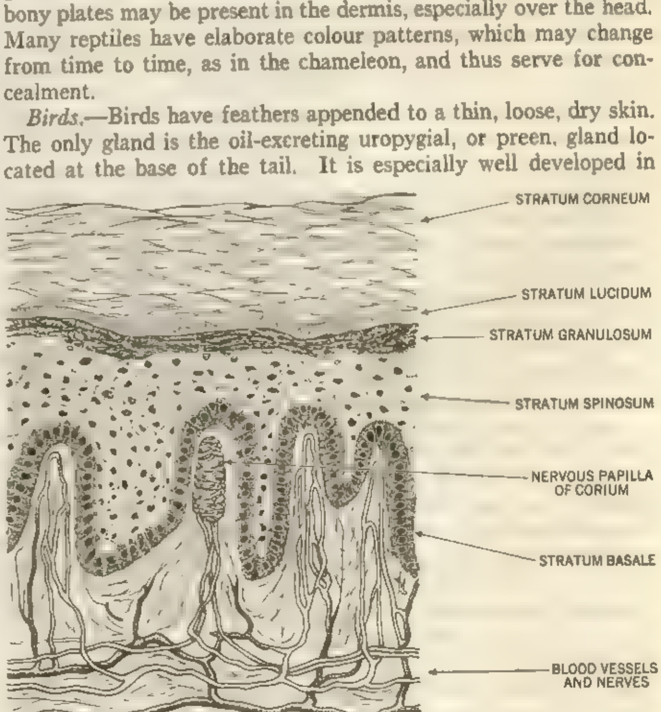
Elasmobranchs.—Among the elasmobranchs, sharks have a very tough skin. Over it are scattered denticles or placoid scales, each with a pulp cavity, around the edge of which is a layer of odontoblasts. These cells secrete the dentine or calcareous material of the scale. Outside the dentine is the enamel, secreted by the overlying ectoderm. Usually the denticles pierce through the ectoderm, after which no more enamel can be added.

Fishes.—The dominant fishes of the modern era are teleosts, characterized by bony scales covered with skin. The epithelium of a trout's epidermis provides the animal with an inert covering of keratin. The scales lie in the dermis as thin, overlapping plates with the exposed part bearing the pigment cells. The scale is deposited in a series of annual rings, since its growth occurs rapidly in spring and summer and hardly at all in winter.

Amphibia.—All adult amphibians have skin that is moist and used for respiration. Its outer layers are horny—a character typical of land vertebrates. In the adult frog the epidermis is renewed at intervals by a process of molting, which is under control of the pituitary and thyroid glands. The wartiness of the skin of toads is due to local thickenings (of interest in considering the origin of feathers and hair). Both mucous and poison glands derived from the epidermis are present in the skin of amphibians.

Reptiles.—The skin of reptiles is dry and contains few or no glands. The outer division is horny or scaly and is shed in flakes; bony plates may be present in the dermis, especially over the head. Many reptiles have elaborate colour patterns, which may change from time to time, as in the chameleon, and thus serve for concealment.

Birds.—Birds have feathers appended to a thin, loose, dry skin. The only gland is the oil-excreting uropygial, or preen, gland located at the base of the tail. It is especially well developed in



FROM CUNNINGHAM TEXT-BOOK OF ANATOMY, OXFORD MEDICAL PUBLICATIONS

FIG. 1.—VERTICAL SECTION OF EPIDERMIS AND PAPILLAE OF DERMIS

aquatic birds. Feathers are the major keratinous structures, but scales like those of reptiles are present on the legs and feet and sometimes elsewhere. The bill and claws are also specialized scale-like structures and may be molted. Nerve endings are present throughout the skin. (*See* also FEATHER.)

Mammals.—The presence of hair appended to the skin (even though the area may be extremely small) is a requisite for classification within the Mammalia. In addition to hairs—both the long tactile bristles and the smaller hairs more generally distributed over the body—the skin appendages may include horns, claws, hoofs, nails, and glands. The armadillo is the only living mammal that has a true bony exoskeleton. (*See* also HAIR; HORN.)

Skin in Man.—The skin of man, from the surface to the point where the dermis merges with the usually fatty subcutaneous tissue layers, varies in thickness from less than 1 mm. ($\frac{1}{25}$ in.) on the eyelids to 3 mm. ($\frac{1}{8}$ in.) or more in the region between the shoulder blades, and on the palms and soles. It is elastic and presents a smooth, soft, pliable surface broken by intersecting lines, folds, ridges, and tiny pores. The more or less parallel, closely set, fine ridge patterns of palmar and plantar skin are characteristic for each individual and form the basis for the widely used fingerprint (*q.v.*) system of personal identification.

Epidermis.—The average thickness of the epidermis is only about 0.1 mm. ($\frac{1}{250}$ in.), although on the palms and soles, or where subjected to rubbing or pressure, it may be 10 to 15 times thicker. The epidermis can be differentiated into several distinct layers (*see* fig. 1). The deepest layer, which rests on the dermis, is called the stratum basale, or basal cell layer, and consists of a single layer of columnar epithelial cells arranged in regular palisade fashion. Interspersed between and slightly below the cells of this layer, along the junction between it and the dermis, is a network of melanin pigment-forming cells (melanocytes) having many slender, branchlike, cytoplasmic extensions; these extensions communicate with one another as well as extend between the cells of the deeper portions of the epidermis, to which they can transfer melanin pigment. There are about 1,000 to 3,000 melanocytes in each square millimetre ($\frac{3}{2,000}$ sq.in.) of skin. (*See* also COLORATION, BIOLOGICAL.)

The layer above the basal cell layer is called the stratum spinosum. This layer is several cells thick; its cells have irregular polyhedral shapes, and they appear to be connected with one another by numerous microscopic intercellular bridges, spines, or prickles. The stratum spinosum and the stratum basale together are sometimes called the stratum germinativum, or Malpighian layer.

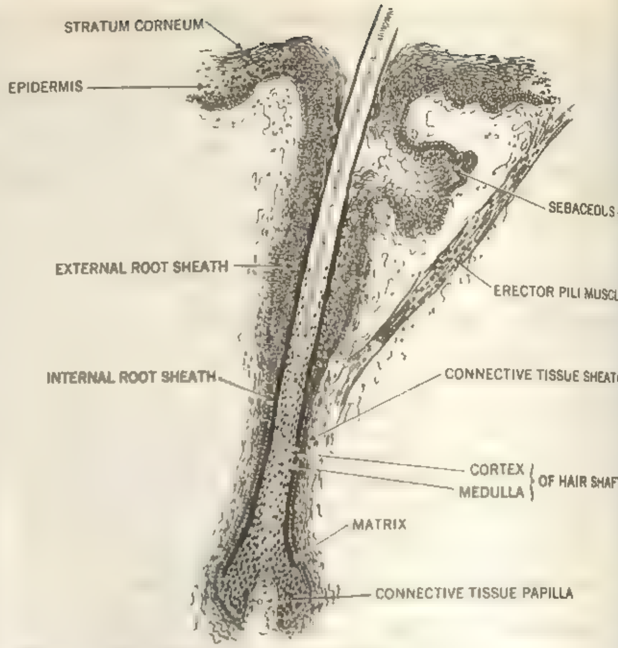
In the next layer, the stratum granulosum, which is from two to four cells thick, the cells become flattened and diamond shaped, and a granular material, keratohyalin, appears in their cytoplasm.

The next layer, the stratum lucidum, is not always apparent. Where well developed it appears as a clear, homogeneous line in microscopic cross-sectional preparations. It contains a lipid-resembling substance, eleidin. The major barrier against the passage of water and salts through the skin lies at the stratum lucidum.

The most superficial layer, the stratum corneum, consists usually of 10 to 20 layers of very flat, dead, dry, keratinized cells, which adhere to one another tightly except nearest the surface, where they are continually shed as microscopic flakes.

Cell division in the epidermis takes place in the basal cell layer and in the lower layers of the prickle-cell layer. As a result of such proliferation, cells are continuously pushed toward the surface. As they move outward they undergo a sequence of changes in which they die, and their proteins become transformed into the tough, chemically inert, fibrous protein called keratin. There are no blood vessels in the epidermis, which therefore has to receive its nutrition from tissue fluids that diffuse through the spaces between the intercellular spines of the stratum spinosum.

Dermis.—The dermis, or corium, has an outer thin, relatively loose, papillary layer adjoining the epidermis and an inner thick, dense, reticular layer that blends into the subcutaneous connective tissue. Papillae of the outer layer (from about 40 to 140 per sq.mm., depending on the region) are tiny, fingerlike processes that fit into sheathlike sockets in the overlying epidermis. The



AFTER A. W. HAM, "HISTOLOGY"; J. B. LIPPINCOTT CO

FIG. 2.—LONGITUDINAL SECTION OF HAIR FOLLICLE

papillae carry capillary vascular loops and also may contain specialized sensory nerve endings. A thin layer of mucoprotein cement substance lies between the corium and the epidermis.

Most of the structural material of the corium consists of the tough, elastic fibrous proteins collagen and elastin. Electron microscopic examination of collagen fibres reveals them to be composed of bundles of very fine fibrils showing a characteristic regular pattern of cross striations. The fibrous components of the corium are imbedded in a complex matrix of ground substance consisting of mucopolysaccharides, proteins, water, and miscellaneous dissolved substances. This ground substance has important functions in regulating diffusion of material through the corium.

The fibres of the corium run in all directions, but predominantly in the plane of the body surface and parallel to the lines of tension and compression of the skin in ordinary movements. (A round puncture wound becomes elliptical after withdrawal of the instrument, and a linear incision gapes more widely if it is transverse to the prevailing fibres.) The corium is well supplied with blood vessels and nerves. Striated muscle extends into the dermis of the face and neck to permit facial movements. Smooth muscle is widely distributed in the corium in the form of thin bundles attached to hair follicles. Their contraction elevates hairs to a more erect position and produces "goose flesh."

Cutaneous Appendages.—The cutaneous appendages in man consist of pilosebaceous units (hair follicles and oil glands), sweat glands, and nails.

The nails are platelike, translucent, keratinous structures that grow over the ends of the fingers and toes from specialized, proximal epidermal matrices called nail roots; these extend to the distal edge of the lunula, a moon-shaped whiter area often visible at the base of the nail plate. Nails consist of densely compacted, highly cornified, dead epithelial cells containing only remnants of degenerated nuclei. The distal edges of the nails are free, and on the fingers serve to assist in the manipulation of small objects as well as for scratching. Six to seven months are required for a newly generated portion of nail to reach the distal free edge.

Eccrine sweat glands occur throughout the skin of man in large numbers, although in many other mammals they occur only on the foot pads. Each gland is an independent, slender, blind tubule about 0.02 mm. ($\frac{1}{1,250}$ in.) in diameter and has two cell layers, an inner epithelial lining (either secretory or ductal in type), and an outer myoepithelial layer of more or less contractile cells. The secretory portion of the gland lies coiled in a ball-like structure in the lower dermis or upper subcutaneous tissue. From there the duct follows a slightly spiral course through the dermis, and then

a much more tightly spiral course through the epidermis and especially the stratum corneum to open in a tiny sweat pore. The total number of sweat glands in man is over 2,000,000, with an estimated tubular length of about 13 km. (8 mi.). These glands actively secrete a watery fluid containing salts. The chief function of sweat secretion in man is the regulation of body temperature by evaporative cooling. Sweat also helps maintain normal hydration of the outer layers of the skin, and on the palms its moisture enhances the grip. (*See* also PERSPIRATION.)

Pilosebaceous units are densely distributed in almost all parts of the skin (fig. 2). Each unit consists of a hair follicle with its hair and its appended sebaceous (oil) gland and erector muscle. In the armpits, perineal and pubic regions, and about the nipples, apocrine sweat glands are also appended to the pilosebaceous units. These glands, which open into the pilosebaceous canal, have a complex, branched, tubular structure; the tubes are about ten times larger than those of eccrine sweat glands. Their mode of secretion also differs: part of the cytoplasm of the secretory cells is pushed off (decapitation secretion). Apocrine secretion is an opalescent fluid that under bacterial action gives rise to substances partly responsible for unpleasant body odours.

Sebaceous glands are multilobulated structures 0.2 to 2 mm. ($\frac{1}{125}$ to $\frac{2}{25}$ in.) in diameter with short ducts that open into the necks of the hair follicles. These glands excrete a highly complex mixture of lipids, called sebum, which diffuses upward in the follicle and impregnates the hair and surrounding horny layers of the skin to participate in forming the greasy skin surface film. This film helps maintain normal pliability of the skin by retarding loss of water from the horny layer, delays absorption of many foreign substances, and contains substances that are protective against exogenous infections. In sebum formation, germinative cells in the periphery of the gland proliferate and, as the maturing cells move toward the centre of the gland, discrete droplets of lipid progressively accumulate in their cytoplasm. Finally these cells burst and liberate the lipid material.

Hair, in man, has little functional value when compared with its role in fur-bearing animals. Nevertheless, human hair has considerable cosmetic and biological interest. Hair filaments are dead, thin, flexible shafts of highly keratinized epithelial cells developing slanting tubular invaginations of the epidermis—the hair follicles. The deepest portion of each follicle is enlarged to enclose a vascular papilla, projecting from the dermis into the bulb. The epithelium immediately above and around this papilla is the germinative matrix for the hair. There are great individual and regional variations in types and distribution of hair. On the scalp, where hair is usually densest and longest, the average total number of hairs is between 100,000 and 150,000. Hair is continually shed and renewed by the operation of alternating cycles of growth, rest, dedifferentiation, and renewal of growth of the hair follicle and its associated structures. This cyclic activity is intrinsic in the individual pilosebaceous units. The average life of different varieties of hair varies from 4½ months for downy hairs to three to five years for long scalp hairs. Scalp hair grows approximately 1 cm. ($\frac{2}{5}$ in.) per month; in persons of European origin it reaches an average length of 60 to 75 cm. (24 to 30 in.). (*See* also HAIR: *Anthropology*.)

Skin Functions.—The skin is a remarkably effective protective barrier against a wide range of injurious chemical, physical, and biological factors. Since it is nearly waterproof it enables the relatively fluid body to exist in dry air, and to be immersed in fresh water without becoming swollen and in salt water without becoming shrunken. The keratinized layers of the skin, which are practically inert chemically and are poor conductors of heat and electricity, also serve, with melanin pigment, as an effective screen against potentially harmful amounts of ultraviolet radiation. Vitamin D is produced in the epidermis when the skin is exposed to sunshine. Body temperature regulation is achieved by the extensive vascular plexuses distributed in the skin and by the cooling effect of sweat evaporation from its surface. Sensory functions are carried out through a rich variety of nerve endings, which bring the primary sensory modalities of touch, heat, cold, and pain into consciousness from discrete receptor points in the skin. Total body respiration, as well as excretion of metabolic wastes, is aided by the skin only slightly. Most substances are very poorly absorbed through intact skin except in the gaseous state. Materials readily soluble in both fatty substances and water are generally better absorbed than those soluble in only one or the other.

BIBLIOGRAPHY.—Stephen Rothman, *Physiology and Biochemistry of the Skin* (1954); William Montagna, *The Structure and Function of Skin*, 2nd ed. (1962); J. Z. Young, *The Life of Vertebrates*, 2nd ed. (1962). (A. L. Lz.)

SKIN, DISEASES OF. The human skin is subject to many diseases, some of them inconsequential and passing, some chronic and productive of prolonged partial or total disability, and others associated with congenital or acquired systemic diseases. Although the cause of many of these conditions is definitely known and the treatment reasonably precise and effective, a large number have no cause definitely established and treatment remains empiric and sometimes unsatisfactory. The diagnosis and treatment of skin diseases is called dermatology, or cutaneous medicine.

Incidence.—Accurate figures on the comparative incidence of various skin diseases were difficult to obtain until World War II, when the medical records of soldiers and sailors of many nations showed that skin diseases were a significant source of disability. From 4 to 20% of patients in U.S. and British military hospitals throughout the world were admitted because of diseases affecting the skin. The percentage was highest in the tropics, where the climate greatly increases the incidence of skin diseases.

Under conditions of dislocation of the population, crowding, and inadequate hygienic conditions, parasitic infestations such as scabies show a sharp rise, as do venereal diseases affecting the skin. Drugs account for a considerable number of skin maladies. Penicillin is a major cause of reactions, usually hives. Sensitiveness to sulfonamide compounds is not uncommon. Many drugs render the skin abnormally sensitive to sunlight (photosensitivity).

Types of Skin Lesion.—A localized, abnormal change in living tissue due to injury (trauma) or disease is called a lesion. The principal types of lesion seen in skin diseases are the following: Maculae are areas of altered skin colour that do not involve swelling or other distortion of tissue. They vary in size from small spots, *e.g.*, freckles, to fairly extensive areas called patches or blotches. Papules are small, solid lesions raised above the skin surface. They are usually conical or rounded in shape and about 1 mm. to 1 cm. ($\frac{1}{25}$ to $\frac{2}{5}$ in.) in diameter. Hives, or wheals, are a kind of papule, usually white or pink in colour, that soon disappears; *e.g.*, mosquito bites. Nodules are rounded or irregularly shaped swellings that are larger than papules and extend well below the skin surface. Tumours are swellings that resemble nodules but are substantially larger and deeper. Any cancerous growth is likely to be called a tumour—though not all tumours are cancerous. Vesicles are lesions filled with clear serous fluid; large vesicles are called bullae (blisters). Pustules (pimples) are papule-like lesions containing pus; they often occur in association with vesicles. Ulcers are open sores resulting from the destruction of tissue. They may extend deep into the skin, and they usually exude pus and other matter which, on drying, forms a scab. (*See* also TUMOUR; ULCER.) An extensive but temporary skin eruption of any kind is popularly called a rash.

Classification.—Diseases of the skin may be classified in several ways. From a systemic point of view, for example, there are (1) those which arise solely within the skin and ordinarily remain confined to it, such as superficial fungal infections and acne; (2) those in which the spread of infection or absorption of toxic agents from the skin may produce disease of internal organs, as in impetigo; and (3) those in which skin changes are an expression of internal disease, as in chicken pox and measles.

In this article, common diseases of the skin are described in groups according to their predominant causative factors. The groups are as follows: (1) Disorders of structure (*e.g.*, moles) and function (*e.g.*, excessive sweating). (2) Acne—the most common disease of the skin—and other conditions arising from endocrine and metabolic disturbances. (3) Noninfectious inflam-

mations: the various forms of dermatitis, or eczema. (4) Infections: those caused by fungi (*e.g.*, ringworm of the scalp, athlete's foot), by bacteria (*e.g.*, impetigo, boils), by viruses (*e.g.*, warts, cold sores, shingles), and by parasites (*e.g.*, scabies). (5) Miscellaneous maladies: psoriasis, hives, photosensitivity, skin cancer, seborrheic keratosis, pemphigus, and congenital conditions.

For details of anatomical structures mentioned in this article *see* SKIN: *Skin in Man*.

Disorders of Skin Structure or Function.—Several skin disorders may involve the pigment cells (melanocytes), located in the basal portion of the epidermis, or outermost layer of the skin. On exposure to sunlight the pigment cells are stimulated to greater output. In brunettes the increase is considerable, and the pigment is laid down evenly, resulting in a deep tan.

Freckles.—In blondes and redheads the pigment cells respond only slightly, and rather unevenly, to sunlight. As a result there is little or no tanning, and the pigment may be laid down irregularly, as freckles. (*See* also ALBINISM.)

Vitiligo (*Leukoderma*) is the loss of ability to form pigment. It is of cosmetic significance only, but may be quite disfiguring in Negroes and other dark-skinned persons. The tendency to it is inherited. The normal skin colour rarely returns, and there is no satisfactory treatment.

Moles.—The pigment cells give rise to ordinary moles, or pigmented nevi (sing., nevus). These contain masses of melanocytes, with nerve elements and connective tissue in thicker lesions. Moles may be flat or fleshy. Their colour varies from almost colourless to bluish, dark brown, or black. They sometimes contain stiff hairs. Moles may be present at birth, but more frequently they appear during childhood. Pregnancy often promotes enlargement of pigmented moles or causes new ones to appear. Moles sometimes disappear in old age. Everyone has some moles, which may number in the hundreds. Occasionally a single mole may cover a considerable area of the body.

Melanomas.—Pigmented nevi are almost always harmless, but they sometimes give rise to tumours known as melanomas. This condition most often arises from a flat, or only slightly raised, and hairless mole. The earliest warning is a change in pigmentation, which tends to become irregular. The development of a zone of pigment around the base, or slow enlargement, is cause for investigation. The entire mole must then be excised surgically, and examined microscopically for evidence of cancer. Malignant melanomas may sometimes develop without any evidence of a preceding mole. (*See* also below, *Skin Cancer.*)

Prickly Heat.—The skin regulates body temperature in part by the evaporation of sweat, produced by glands in the underlying layer of the skin. When ducts are blocked, as in sunburn or eczema, the sweat may be trapped. If the blockage is superficial, tiny blisters appear, but are of no consequence. Deeper blockage results in an inflammation called prickly heat (miliaria). This produces itching, which can be continuous and intense in a warm climate. The itching usually ceases promptly in cooler surroundings.

Excessive Sweating.—Sweating is greatly influenced by emotional stimuli. Under severe stress, almost anyone will react with increased sweating of the hands, feet, and armpits. In some persons the reaction occurs from the ordinary stresses of living, and this excessive sweating (hyperidrosis) may be almost continuous and very annoying. (*See* also PERSPIRATION.)

Seborrhea and Wens.—Hyperactivity of the sebaceous (oil) glands produces excessive oiliness of the face, scalp, centre of the chest, and genitalia, where these glands are most numerous. Often there is yellowish scaling (*see* below, *Seborrheic Dermatitis*). Occasionally a saclike growth called a wen develops from a sebaceous gland; it is filled with sebum and keratin, and is unsightly but benign (although subject to bacterial infection). Draining the contents is useless, since the wen soon fills again; surgical removal may be required.

Chapping.—The skin surface is kept supple by the oily secretion of the sebaceous glands and by fatty substances supplied from the epidermis. The stratum corneum (outermost, horny layer of the skin) also contains a fairly constant water content. Under very dry conditions, as in overheated houses in cold weather, the amount of water in the stratum corneum may drop below a critical level, with loss of elasticity and resultant chapping and fissuring. (*See* also below, *Ichthyosis.*)

Bedsores are ulcerations of the skin over bony prominences, *e.g.*, the hips or elbows, of bedridden persons. They may be caused by interrupted circulation due to body pressure upon the mattress, or by friction against the bedclothes. The condition is aggravated by uncleanliness, which also increases the danger of secondary infection. Prevention and treatment of bedsores includes frequent changes of position, daily bathing, and the application of lotions.

Chilblains are red or purplish patches that itch and burn. They usually occur on the hands, feet, and legs, and are commonest in children and young women. Chilblains result from exposure to alternate extremes of heat and cold.

Calluses and Corns.—The skin responds promptly to physical or chemical injury. With chronic rubbing, as from a tight shoe, the epidermal cells become much more active and horny tissue increases at the skin surface. This localized thickening is known as a callus, or callosity. If it has a conical shape, penetrating the dermis and causing pain when pressed, it is called a corn.

Acne Vulgaris.—The most common of all chronic skin diseases, acne is so frequent during adolescence as to constitute almost a normal physiological response to puberty. With the normal rise in circulating hormones of the male type, with development of secondary sex characteristics such as the growth of pubic and axillary hair, the size and activity of the sebaceous glands also increases. At the opening of the follicle (pore) through which hair grows and the sebaceous gland empties, a plug known as a blackhead appears, and is followed by the typical acneous pustule.

Mild acne frequently clears up spontaneously, with little or no residual pore enlargement or scarring. The reasons for this spontaneous cure are uncertain. More severe cases involve inflammation, with repeated infection or chemical irritation and disturbance of the precise cellular arrangement of the epidermis. In such cases acne may continue into the twenties or even longer, and produce irreversible scarring. The psychic implications of prolonged severe acne are often considerable, and young individuals so afflicted may become depressed and withdrawn. Treatment must include some psychotherapy in addition to other measures.

The treatment of acne is far from satisfactory in terms of producing prompt, permanent subsidence of all signs of the disease. In mild cases, where spontaneous involution may be anticipated, drying lotions containing sulfur, resorcinol, and other agents are ordinarily helpful, along with careful drainage of superficial pustules and the gentle expression of blackheads. Picking or pinching the lesions can be very harmful, and may become an almost uncontrollable habit. Regular washing of the face is advisable, though this should not be too frequent or strenuous. Reasonable use of cosmetics is not harmful. The relation of flareups to ingestion of particular foods should be watched for. Dietary restrictions usually include the avoidance of chocolate, nuts, and cola drinks.

Sunlight ordinarily has a beneficial effect on acne. If the weather is warm and muggy, severe exacerbation of acne may occur (so-called tropical acne). In females, exacerbation of acne is frequently noted before or during menstruation.

Antibiotic and sulfonamide therapy is widely used in severe acne in which infection is obviously present. However, approximately one person in three does not show any lasting response to such treatment. Therapy must be long continued and, in the case of the antibiotics, is expensive.

Since the basic reason for the development of acne is the presence of androgenic hormones, many kinds of hormonal treatment have been tried. None is entirely satisfactory and free of side effects. In males the administration of hormones of the female type (estrogens) is helpful; however, the doses are necessarily large and will produce undesirable feminizing effects in time. In females the administration of hormonal contraceptive compounds has a good effect on acne, though this effect is not ordinarily apparent until treatment has been given through three or four menstrual cycles.

Deficiency Diseases.—Improper diet causes a number of diseases involving the skin. One of the most serious of these is pellagra (*q.v.*). For deficiency diseases generally, *see* MALNUTRITION.

Dermatitis and Eczema.—A dermatitis is an inflammation of the skin not caused by an infectious agent. It may be caused by many substances. Dermatitis is characterized by redness, swelling, blister formation, oozing, and (almost always) itching. Eczema is, essentially, a chronic dermatitis. Dermatitis and eczema may be classified in the following principal types:

Contact Dermatitis results from contact of the skin with an irritating substance or a substance to which the person is allergic (*see* ALLERGY AND ANAPHYLAXIS). Inflammation resulting from contact with a strong chemical, such as a concentrated acid or alkali, is called a primary irritant dermatitis. There is no allergic component in this. Other substances causing contact dermatitis are not primarily irritant in themselves but produce a reaction in persons sensitized by previous exposure to the substance.

The most common cause of allergic contact dermatitis in the United States is poison ivy (*q.v.*) and its relatives. Individuals are not born with the sensitivity, but acquire it by repeated exposure to the plant substance. Many other plants are capable of causing sensitization; *e.g.*, the European primrose. (*See* POISONOUS PLANTS: *Plants Poisonous on Contact.*) Chemical compounds that may cause allergic contact dermatitis include penicillin, sulfonamides, paraphenylenediamine dyes, and chromates.

Atopic Dermatitis, also called allergic infantile eczema and disseminated neurodermatitis, is a highly characteristic, itching type of chronic dermatitis. It appears most commonly in tense, nervous persons, especially those with dry skin. The tendency is inherited. Evidence of related allergic disturbances such as hives, hay fever, and asthma is found in the family members or in the afflicted person. Severe cases are difficult to control medically.

Seborrheic Dermatitis (*Dandruff*) manifests itself as scaling of the scalp, which is often oily. Inflammation may appear in other areas of the body; *e.g.*, behind the ears, in the armpits, and in folds of the skin. The term dandruff is a rather inexact one, simply indicating excessive scaling of the scalp. Although the most characteristic type is seborrheic dermatitis, dandruff also occurs in persons with dry skin. Some dandruff is caused by psoriasis (*see* below) which has not been recognized. Infections, particularly of the ringworm variety, also may produce scaling.

Localized Neurodermatitis (*Scratch Dermatitis*).—Occasionally, localized areas of skin become itchy although there is no apparent source of irritation. The process is perpetuated by scratching. The scratching substitutes pain for the itch, but the itching soon returns and the scratching is repeated.

Chronic Dermatitis of the Hands and/or Feet.—The hands are susceptible to inflammatory disease because of chemicals with which they come in contact; the feet, because of shoes, which harbour fungi and bacteria causing superficial infection.

Stasis Dermatitis is a characteristic inflammation of the ankles and lower legs in persons suffering from interference of return circulation, usually due to varicose veins (*q.v.*). The dermatitis is chronic, and ulceration may occur. An essential part of treatment is to relieve the stasis (stoppage of blood flow) by supportive stockings or by surgery on the varicose veins.

Dermatitis Medicamentosa (*Drug Eruption*).—Almost any drug is capable of producing a sensitization reaction. The reaction may be a dermatitis, hives (*see* below), or a mixture of various skin lesions with large blisters. It is estimated that 8 to 10% of the U.S. population is sensitive to penicillin in varying degrees. The most common reaction to penicillin is the development of hives, sometimes of large size.

Fungus Infections.—Fungi, a class of primitive plants, include microscopic organisms capable of producing infections, either confined to the skin surface (superficial infections) or involving internal organs as well as the skin (deep infections).

Ringworm (*Tinea*) is the inclusive name for a number of superficial infections caused by the fungi *Trichophyton* (the most common genus), *Microsporum*, and *Epidermophyton*. These organisms feed on keratin, the protein building-material of the nails, hair, and stratum corneum. Most ringworm infections respond well to treatment with griseofulvin, a fungicidal antibiotic.

Ringworm of the Scalp (*Tinea Capitis*) is highly contagious among children. Within the round, spreading lesions the hairs become brittle and break off at the skin surface. The disease has declined in Western communities; it formerly was epidemic in institutions such as orphanages. The common types of ringworm of the scalp are easily detected by a characteristic fluorescence when examined under ultraviolet light with a special filter.

Favus (*Tinea Favosa*) is another type of ringworm, now rare. The cuplike, yellow-crusted lesions occur most commonly on the scalp, and may itch intensely. The condition is chronic and contagious. Favus sometimes results in permanent, patchy baldness.

Pityriasis (*Tinea Versicolor*) is a fungus infection that produces, mainly on the upper trunk, numerous blotchy macules that vary in colour from white to pinkish-buff to brown. The disease is chronic, and of cosmetic significance only; it is not contagious.

Athlete's Foot.—The most common site of this type of ringworm infection is the feet. The incidence is higher in males than in females. Because infection ordinarily begins in early adult life, and because it was erroneously thought to be transmitted in gymnasiums and swimming pools, the term athlete's foot became popular. However, irritation of the skin of the foot can be caused by many agents other than fungi, and the diagnosis must be proved by the demonstration of fungi in scales scraped from the skin surface or the toenails. Inflammation between the toes may be produced by moisture alone, through excessive sweating or failure to dry thoroughly after bathing; or by the superficial bacterial infection known as erythrasma (*see* below).

Jockstrap Itch is a fairly common superficial fungus infection in the groin in males. It is characterized by round, scaling patches. Diagnosis must be confirmed by demonstration of the organism, since other maladies tend to involve this area as well. If a ringworm infection is present it is ordinarily quickly controlled by griseofulvin, scrupulous hygiene, and the prevention of irritation, as from the wearing of a jockstrap. Women occasionally have a ringworm infection in the groin, but the inflammation is more frequently candidiasis or erythrasma.

Candidiasis (*Moniliasis*) is caused by the same yeastlike organism that produces thrush (*q.v.*) in the mouth. It occasionally occurs in the vagina, with accompanying inflammation of the vulva and perianal region. The organism also attacks the webs of the fingers and the nails of housewives, bartenders, and others whose hands are often wet. As a skin disease it is most frequent in obese persons and diabetics. It occurs with some frequency in persons receiving broad-spectrum antibiotics over an extended period of time. Candidiasis is treated with the fungicide nystatin.

Deep Fungus Infections.—Certain fungi are capable of invading internal organs as well as the skin and mucous membranes. Blastomycosis, found mainly in the midwestern U.S., produces skin ulcers. Many persons are infected and recover spontaneously without being aware that they have had the disease. Coccidioidomycosis (valley fever) is found mainly in the San Joaquin Valley of California, though cases have been reported elsewhere. Infection begins in the lungs when the spores of the fungus are inhaled. A characteristic feature is the development of inflamed nodules on the lower legs. A high proportion of residents of the endemic areas acquire the infection, and all but a few recover spontaneously. *See* also FUNGUS INFECTIONS.

Bacterial Infections constitute another major group of skin diseases. They may occur suddenly and acutely on normal skin.

Impetigo, usually caused by staphylococci, is marked by purulent lesions that become thickly crusted. In some cases there are severe systemic complications. The disease is extremely contagious among infants, but not particularly so among older children and adults. Infections in nurseries may often be traced to an adult carrier. The lesions are treated by cleansing with soap and water, followed by application of a broad-spectrum antibiotic ointment. Systemic antibiotic therapy is sometimes necessary.

Boils and Carbuncles (*Folliculitis*).—When bacterial infection is mainly around hairs, superficial folliculitis or a deeper boil occurs. If several boils coalesce a carbuncle results, forming a dangerous lesion in old or debilitated persons. Some individuals, often

young and in otherwise excellent health, are susceptible to recurrences of boils, for reasons not fully understood.

Erythrasma is a bacterial infection resembling a dark, blotchy type of ringworm, with which it was long confused. Most prevalent in warm climates, it is treated with oral antibiotics.

Erysipelas is a form of cellulitis (disease of the subcutaneous tissue) caused by streptococci. The red, plaquelike swellings are seen most commonly on the face and scalp, and may recur at the same site. The disease is accompanied by lassitude and fever. It is treated with bed rest, cool compresses, and antibiotics.

Leprosy.—*See* LEPROSY.

Venereal Diseases (*q.v.*) are prominent among the many systemic bacterial infections which are characterized, at some stage, by skin lesions. Pinta, a disease encountered in the American tropics and caused by a spirochete, is of special interest. It involves bizarre changes in the colour of the skin, which may become white or a shade of blue, brown, or red.

Virus Infections.—Many virus infections produce lesions of the skin. Some of these are systemic infections; *e.g.*, measles and chicken pox (*qq.v.*). This section discusses virus infections that remain entirely or almost entirely within the skin.

Warts are extremely common. They can be spread from one part of the skin to another. In moist parts of the body, as around the anus or genitalia, warts may be large and exuberant (venereal warts—a term that does not imply venereal disease). Warts on the sole of the foot (plantar warts) may cause considerable pain and disability in walking. Warts are definitely contagious, not infrequently occurring in several members of the family or on the feet of persons who walk barefoot on contaminated floors. Warts may appear or disappear for no apparent reason. In children especially they may be successfully treated by psychotherapy or by folk remedies of the "hexing" kind. No known compound has a specific effect on the virus. Methods of treatment include application of a cauterant compound; freezing with liquid nitrogen; and electrosurgery.

Herpes Simplex (*Cold Sore, Fever Blister*) occurs most frequently on or near the lips but may be seen on the genitalia and in other places. It may recur repeatedly at the same site. The initial infection apparently occurs sometime during childhood; among infants it may produce marked systemic illness, with extensive lesions of the skin and mucous membranes, but among older children the first infection may go undetected. Recurrence is triggered by a variety of factors, such as an upper respiratory infection, excessive exposure to sunlight, the menstrual period, emotional tension, and possibly a food or a drug. There is often tingling or burning in the affected site for a few hours to a day or two before the onset of redness and a round cluster of blisters. The lesion is usually single, but occasionally there may be more. The blisters gradually dry up in about a week and are replaced by a scab. Ordinary cases are treated with drying lotions or solutions. Supportive therapy is given in cases of severe initial infection in infants, and for persons with eczema, particularly infants or children, who sometimes develop very widespread cold-sore lesions that look much like chicken pox and may be accompanied by high fever. Herpes simplex about the eye may sometimes involve the eye itself (herpetic keratitis).

Herpes Zoster (*Shingles*) is caused by the same virus as that of chicken pox. The virus affects the skin and nerves. Herpes zoster has a characteristic linear distribution following a nerve segment, along which are seen round groups of small blisters similar to, but usually much larger than, those in herpes simplex. Most common on the back, lesions extend from the spine toward the chest. However, any nerve segment may be involved; *e.g.*, the lesions may extend down a leg or an arm. The most serious type of herpes zoster involves the first branch of the fifth cranial (trigeminal) nerve, which supplies the scalp, forehead, and the region of the eye; the lesions may cause severe eye damage. The symptoms and the severity of lesions vary with age. Before any lesions appear, there is frequently a dull ache for a day or so in the affected site. In most young persons the lesions are hardly more severe than those of a cold sore; in aged persons or those debilitated by some systemic disease, the pain and inflammation may be severe. Occasionally the pain persists long after evidence of inflammation has subsided (postherpetic neuralgia). Herpes zoster is treated with soothing powders or lotions, and pain-relieving drugs.

Parasitic Infestations.—Many insects regard man as an attractive food or habitat. Biting insects such as mosquitoes, flies, and ticks produce local reactions in the skin varying from a small hive to a large blister. Bees, wasps, and hornets inject a venom, producing reactions of a severity that depends on the sensitivity of the person bitten. (*See* INSECT BITES AND STINGS.)

Pediculosis is the name of skin disorders caused by various species of lice that infest the scalp, groin, and body. Good hygienic practices and the availability of miticides such as DDT have made louse infestations rare in civilized communities.

Scabies is caused by the itch mite, *Sarcoptes scabiei*. The female burrows into the stratum corneum, laying her eggs in a tunnel that can be seen as a dark wavy line. The initial lesion is soon obscured by the secondary lesion, which usually takes the form of hives or scratch dermatitis (as the result of itching). Common sites of infection are between the fingers, in the genital region in men and the breasts in women, along the belt line, and about the elbows and wrists. Under conditions of poor hygiene and crowding, scabies may become epidemic. Transmission occurs almost entirely by skin-to-skin contact and not to any appreciable extent through wearing apparel and bedding.

Psoriasis is a fairly common and extremely persistent skin disease of unknown origin. The age of onset varies from infancy or early childhood to age 65 or later; usually, however, the disease begins in early adult life. A tendency to psoriasis is inherited.

The typical lesion of psoriasis is a red, sharply circumscribed patch with silvery scales. The most common sites are the scalp, the elbows, and the knees. The disease may remain in rather diminutive form for many years; at times it may become more extensive, with numerous lesions on the trunk and the extremities. A characteristic involvement of the nails is seen; this may be confused with ringworm infection.

Treatment of psoriasis is often discouraging, and no method will effect a permanent cure. Exposure to sunlight often is helpful. Medications usually contain mercury, tar, salicylic acid, sulfur, and anthralin, singly or in combinations. The best single local medication is a cream or liquid containing a potent corticosteroid.

Hives (Urticaria).—This is a local and usually transitory edema of the skin produced by the release of histamine (*q.v.*) and, probably, other substances. The condition may be short-lived or chronic. A simple example of a hive is the reaction resulting from an ordinary mosquito bite. The most common cause of extensive hives is penicillin or a compound chemically related to this antibiotic. Other drugs may give rise to urticaria, depending on the person's sensitivity. Foods may also produce these lesions. In some persons, hives persist or recur for months or years. The cause in such cases is difficult to determine. Psychological factors may have a dominant role. Some persons tend to develop hives wherever trauma is exerted on the skin, such as by rubbing the finger firmly over it; this is called dermographism.

Photosensitivity.—Many persons are intolerant to sunlight. This is especially true of blondes and redheads, whose skin is reddened by relatively brief exposure to the sun, and in whom the protective responses to sunlight, such as thickening of the skin and tanning, do not come into play. In rare instances infants are born with a very marked intolerance to sunlight. Persons with liver disease, particularly that caused by alcoholism, and the biochemical disturbance known as porphyria (*q.v.*), may become intolerant of sunlight. An increasing number of drugs are known to produce photosensitivity.

Lupus Erythematosus is a disease that is exacerbated by sunlight. The cause is not known. Chronic discoid lupus erythematosus is characterized by red patches that appear chiefly on the bridge of the nose, the cheeks, and the scalp. The borders of the lesions have a gray scale which extends into the dilated follicles. There may be residual scarring. Antimalarial drugs are effective in treatment. A far more serious form is systemic lupus erythematosus, a collagen disease (one involving connective tissue in blood vessels throughout the body). Symptoms include fever, pain in

the joints, and distress caused by lesions in the kidneys and elsewhere. Red, patchy skin lesions occur in about half the cases; they are commonest on the face but also may involve the hands and chest. The prognosis is unfavourable, because of complications. Treatment consists largely of the administration of corticosteroids to abate the symptoms. (Lupus vulgaris, or tuberculosis of the skin, is not related to the two diseases just discussed. It is marked by nodular lesions that produce scarring.)

Skin Cancer.—The possibility of curing most types of skin cancer approaches 100% if the precancerous or cancerous condition of the skin is recognized early and the tumour is promptly eradicated. The only cancerous lesions to which this statement does not fully apply are the malignant melanomas (*see* above) arising from moles.

There are many types of skin cancer. Most of them arise from the skin itself, but occasionally they result from cancer of internal organs or from leukemia. Most skin cancers are of two types: basal-cell epithelioma (rodent ulcer) and squamous-cell (prickle-cell) epithelioma. Basal-cell epithelioma lesions are ordinarily slow-growing, and may require years to achieve a size of 1 in. ($2\frac{1}{2}$ cm.) in diameter. They have a characteristic appearance to the practised eye, and may be recognized very early in their course. They occur most frequently on exposed areas, especially where the sebaceous glands are most numerous. Fortunately these tumours invade only by local extension, and do not spread through the lymphatics or bloodstream to other parts of the body. Squamous-cell epithelioma is a more malignant type, which may spread to neighbouring lymph nodes and other structures, particularly in the case of tumours on the lips. This type of cancer is the most common one occurring within the mouth. Squamous-cell epithelioma is almost always preceded by a rather long-standing precancerous lesion, usually a senile (actinic) keratosis (a small, wart-like lesion) seen most commonly in areas which have had chronic exposure to sunlight.

Certain chronic stimuli are known to promote degenerative changes in the skin which may result in cancer. By far the most important of these is excessive exposure to sunlight. The incidence of skin cancer is highest in sunny regions such as the southwestern U.S., and the disease most often afflicts persons whose work or recreation keeps them in sunlight a great deal; *e.g.*, farmers, sailors, fishermen, and sunbathers. The more common types of skin cancer are practically unknown in dark-skinned Negroes, whose pigmentation is a defense against sunlight.

Seborrheic Keratosis.—This very common skin lesion is frequently misinterpreted as a skin cancer or mole. The lesions begin as light-coloured, rough-surfaced, slightly raised papules which gradually darken and extend in size. They are seen most frequently on the trunk, especially on the shoulders and back; some persons have a great many of them. Women frequently develop the lesions on the sides of the neck. These keratoses are of cosmetic significance only, and are easily removed by surgery.

Pemphigus is a disease of unknown cause which involves degeneration of tissue. Blisters that form in the mouth and throat leave raw areas when they rupture; those that form on the skin (which acquires a distinctive odour) are followed by the exfoliation of large scales. Pemphigus may be fatal unless treated intensively with corticosteroid drugs.

Congenital Conditions.—The general characteristics of the skin are, of course, genetically determined. The number of congenital defects is very large, but fortunately most of them are rare. However, two are so common, and at times so disabling or disfiguring, as to deserve mention.

Ichthyosis (*Fishscale Skin*).—Some individuals are born with very dry skin. The mechanism involved is a greatly increased adherence of the dead cells of the outermost, horny layer. The surface is dry and rough, is intolerant of even the mildest irritants, and has a tendency to severe chapping and fissuring, especially in cold weather. These persons may also have a deficiency of sweat glands and occasional associated disturbances of the growth of hair, teeth, and nails.

Hemangiomas (*Vascular Birthmarks*) are malformations of the blood vessels of the skin. The most frequent type is immature (strawberry) hemangioma, which may be present at birth or appear shortly thereafter. It is a bright-red nubbin composed principally of small capillary blood vessels. The lesion ordinarily enlarges for several months or a year, and occasionally becomes ulcerated. Strawberry hemangioma usually recedes after the first year of life, and no treatment may be necessary. A second, very common type is flat hemangioma (port wine stain, nevus flammeus). The most frequent site is the back of the neck; less frequently it is on or near the eyelids. Sometimes the lesion may be large and prominent, and can be very disfiguring if on the face. There is no satisfactory treatment, but the area can be satisfactorily obscured by heavy make-up preparations. A third, much less common type is mature (cavernous) hemangioma. This is present full-blown at birth, is composed of rather large blood vessels and other tissue elements, and does not change in size except in relation to the growth of the part involved.

SKIN, SENSORY FUNCTIONS OF. Sensory nerve impulses from the skin are employed either in keeping the organism informed of its relationship with its immediate surroundings, or in the control of mechanisms for counteracting the effect of changes in the physical conditions within or at the surface of the skin. Thus, the sensory functions of the skin are not concerned solely with conscious experience.

This complex role can be demonstrated in many ways. For instance, if a beam of infrared radiation (heat energy) is transferred to the skin at a suitable rate, a report of warmth is evoked; the temperature of the skin surface starts to rise, at first rapidly, then more slowly until a steady state is reached, despite the fact that heat is still being transferred to it at virtually the same rate. The new state of equilibrium is brought about by reflex action. The sensory impulses evoke a discharge of motor impulses which result in a local increase in the blood flow, thus enabling the heat to be removed as fast as it is received. As soon as the surface temperature of the skin stops rising, the sensation of warmth is no longer perceived despite the fact that the skin is still being irradiated.

By contrast, if the experiment is repeated, using a much greater rate of heat transfer, the subject will almost instantaneously withdraw from the path of the beam and a report of pain will be made even though the actual rise in temperature of the skin surface has not been particularly large.

These observations make it clear, among other things, that the conscious experience evoked by stimulation of the skin is conditional both upon the physical characteristics of the stimulus and upon the conditions prevailing within the skin itself at the time of stimulation. In other words, in respect of heat transfer, the skin does not behave like a thermometer, for the number of impulses reaching the central nervous system from the skin does not merely reflect alterations in the physical state of the environment but also depends upon the changes brought about in the skin itself.

Further, even if the nerve impulses reaching the central nervous system from the skin do not vary, the conscious experience evoked depends upon the precise conditions prevailing in the central nervous system at the time of stimulation. Stimuli which consistently evoke reports of pain in a subject at rest may fail to reach consciousness when the same person is absorbed in a game of chess.

Although the sensory functions of the skin are not limited to arousing conscious experiences, these are of the more immediate interest, primarily because of their well-known relationship to dis-

ease and also because more is known about them than about most of the other sensory functions of the skin.

Physical Background of Common Sensibility.—It was formerly believed that the skin contained a mosaic of discrete nerve terminations divided into four species, each of which was specialized structurally and functionally to serve one of the primary modalities of common sensation; *i.e.*, touch, warmth, cold, and pain.

This concept probably arose directly from the necessary codification of common experience into convenient abstract terms. Moreover, it proved to be a useful working hypothesis, for it led to the recognition that impulses which evoke pain travel up to the brain in a different part of the spinal cord from those transmitting detailed tactile information. However, more critical and refined work (discussed below) has yielded observations which cannot be reconciled with the earlier view.

Anatomy of the Cutaneous Nerve Terminals.—The greater part of the human body in both sexes is covered with hairy skin, although the hairs in certain zones are so fine that they cannot be seen without the aid of a lens. Indeed, the only zones where hairs are entirely absent are the palms of the hands, the soles of the feet, and certain exposed mucous membranes, such as those of the lips, the anus, and parts of the external genital organs. In hairy skin there are only two kinds of nerve termination: (1) compact basketlike networks surrounding the necks of the follicles through which the hair shafts pass and (2) diffuse arborizations of fine filaments which intermingle extensively with one another and end freely and at random among the various tissue elements in the skin; all of these arborizations are anatomically alike. In hairless zones, compact nerve entanglements of diverse shapes and sizes, often enclosed within cellular capsules, take the place of the basketlike networks around the hairs, but it is not possible to classify them into sharply demarcated groups.

These observations strike at the roots of the hypothesis upon which the mechanism of cutaneous sensibility was originally erected. For it is clear that over the greater part of the body there are only two types of nerve terminal to subserve four sensory modes. Further, since it is unlikely that the stimulation of hairs arouses in conscious experience sensations unrelated to touch, the diffuse arborizations must be related, among other things, to the conscious experiences reported as warmth, cold, and pain.

Pattern of Innervation of the Skin.—It has been demonstrated that individual nerve terminals do not have private lines of communication passing directly to the central nervous system. On the contrary, each parent nerve subserves many terminals which are evenly scattered over a relatively large area by means of a mazelike network of nerve fibre bundles in the skin itself. Indeed, the arrangements are such that random destruction of up to one-quarter of the parent nerve fibres in a sensory nerve trunk (a bundle into which parent nerves are gathered as they pass from the skin to the spinal cord) results in degeneration of a small proportion of nerve terminals evenly scattered throughout the area of skin subserved by the whole trunk. Moreover, the subject is usually quite unaware of any alteration in the sensory capacity of the skin involved; certainly none can be detected by the use of such test objects as needles and wisps of cotton wool.

Although little quantitative information concerning the pattern of innervation of human skin had been obtained by the mid-1960s, the innervation of the hairs in the skin of the rabbit ear had been analyzed in some detail, and comparative studies leave no doubt that hairs are innervated on the same principle in man. Briefly, the number of hairs in the rabbit ear is about five to six times greater than the number of parent nerve fibres leaving the ear. In the ear itself each parent nerve is served by numerous branches which come from hairs scattered over areas ranging in size from a few millimetres square to as much as half the ear. Moreover, the area served by one parent fibre always overlaps that supplied by others. Thus even the smallest hairs are served by branches from at least two parent nerves, large so-called guard hairs by as many as 20, and medium-sized hairs by about 5 or 6. It has also been found that individual hairs are connected with parent nerve fibres of slightly different thickness which conduct impulses at different speeds so that they reach the spinal cord at different times. In addition to this, the hairs themselves are so grouped that it is virtually impossible to stimulate a single hair in isolation, unless it be a large guard hair (which is served by many parent axons), by any form of naturally occurring stimulus. Thus, any significant stimulus must result in a highly complex spatiotemporal pattern of impulses reaching the cord. The sensory experience evoked must therefore be the result of the integration of this pattern of impulses with other incoming patterns, the transfer of the new pattern which emerges to higher centres where further integration probably takes place, and the final transfer of resulting activity to circuits responsible for perception.

In the case of the rabbit, it has been calculated that these peripheral arrangements require fewer parent nerve fibres to carry an equivalent amount of information as compared with the system envisaged in the original hypothesis, which assumed that each terminal in the skin had a private line of communication with the central nervous system. A corollary of this is the negligible effect on sensory acuity caused by destruction of up to one-quarter of the parent fibres in any part of a sensory nerve trunk passing between the skin and the spinal cord. Focal disturbances of sensation within the area supplied are not encountered.

Density of Innervation.—This varies considerably from place to place over the body surface. The skin of the back, for example, is not subserved by so many parent nerve fibres as the skin of the face and of the extremities, particularly that of the palms and soles. However, the nerve terminals which end freely within such sparsely innervated areas of skin are almost as numerous as (though they are finer than) those in more densely innervated zones.

Skin which is supplied by a large number of parent nerve fibres is generally capable of resolving fine details in the configuration of the environment. For instance, the fingertips can be used by blind people for reading by the Braille System. Pain evoked from lavishly innervated areas, such as the face, is always reported as being more intense, and it certainly is more likely to cause fainting than that evoked by the same stimulus from less densely innervated areas of skin.

The effect of stimulation on conscious experience is not, however, always directly proportional to the density of innervation of the area concerned. The foreskin and mucous membranes of the glans penis and clitoris are among the most lavishly innervated surfaces of the body, in terms of both parent nerves and the density and size of their terminal ramifications. Yet these regions are virtually "silent" as compared with those covering the trunk when the same stimulus is used. Moreover, the sensation evoked is peculiarly uninformative, as regards both the position and clarity of image which is perceived. Despite this apparent insensitivity it is known that a large outburst of activity follows stimulation of the monkey's glans penis with a wisp of cotton wool even when the animal is fully anesthetized. Division of cutaneous nerve fibres in this region (*i.e.*, circumcision) evokes pain of greater intensity than that which follows an incision of comparable length in skin elsewhere.

It seems, then, that the nature of the conscious perception evoked by naturally occurring stimuli (short of severe injury) in these zones is not dependent upon the sensory impulses evoked but solely upon the state of the nerve cells to which the impulses are conveyed, in the spinal cord or elsewhere. The mechanism apparently is such as to prevent the majority of impulses reaching the level of consciousness except upon specific occasions.

Specificity of Nerve Terminations in the Skin.—It is accepted that the nerve terminals related to hairs and compact nerve terminals help to keep the organism informed about its environment. It is, then, of more than passing interest to find that such endings, as well as the spinal tracts associated with them, are absent in aquatic animals, whose watery environment is relatively homogeneous, and where such information is presumably less necessary to survival. It is not known whether hairs can be stimulated in such a way that nerve impulses specifically related to the terminals evoke reports of pain. It is not possible to cause pain simply by vibrating hair shafts mechanically at

speeds which are either about the same as or greater than the number of impulses the nerves serving them could signal.

Vibration in a single plane, however, is unlikely to stimulate maximally and simultaneously all the nerves which serve as hair. Pulling hairs out of the skin is certainly painful, but this not only damages the nerves of hair shafts but also damages the nerves serving neighbouring structures. The latter nerve endings are of the diffuse type and the ones most likely to be responsible for the pain. However, in certain pathological conditions in which the normal pattern of nervous impulses from hairs in a given area is disturbed, the sensations evoked by their stimulation are referred to as "unpleasant" and at times "painful," but the subject always adds that sensations are not of the kind he experiences in everyday life and he is unable to describe them adequately. In this connection, it is perhaps significant that tactile stimulation in man under local anesthesia of the spinal pathways conducting the impulses from hairs (and other proprioceptive organs; *i.e.*, impulses from deeper structures) gives rise to a report of intolerable pain.

More is known concerning the specificity of diffuse nerve endings, although the evidence concerning their precise function in human skin is indirect. It is possible that, despite their close interrelationship, complex patterned arrangement, and lack of anatomical differentiation, they may be highly specific from a functional point of view. Unfortunately, there is no known area of human skin subserved solely by nerves which end diffusely. They are invariably accompanied by nerves which form compact terminals of one kind or another, which may affect the sensory experience they evoke. However, the transparent covering of the eye, the cornea (*see* EYE, HUMAN: *Anatomy and Physiology of the Eye*), does contain only diffuse nerve endings. It is true that it is structurally unlike skin, but it is highly significant that when it is suitably stimulated, reports in each of the four primary modalities are invariably evoked. Fortunately, the microscopic anatomy of the cornea varies little among the higher animals, including man. Moreover, it is a relatively uncomplicated tissue in that it contains neither blood vessels nor nerves having other than sensory functions. In the cat it has been shown that one and the same nerve ending discharges impulses along its parent nerve when the cornea is stimulated by objects which in man evoke reports related to each of the four sensory modes. The amount of activity evoked by a particular stimulus varies from ending to ending. Moreover, different stimuli evoke different patterns of activity from the same ending. For instance, light touch evokes a short, high-frequency outburst in the case of all active terminals. Injury (pain) evokes a prolonged outburst, the frequency of which depends upon the degree of damage which has been inflicted. Thermal stimuli usually evoke a discharge with a sharp rise and fall in frequency. In the case of some terminals, the activity evoked by warmth is far greater than that evoked by an equivalent amount of cold and vice versa; in the case of others, the responses evoked by either warmth or cold are indistinguishable. More rarely, while tactile and injurious stimuli evoke activity from the terminal, thermal stimuli are ineffective. These observations strongly suggest that stimuli having different physical characteristics evoke different patterns of activity from nerve endings, the specificity being due to their varied environmental conditions.

Conclusions.—The anatomical configuration and arrangement within the skin of the cutaneous nerves and their terminals are such that it is probable that the great majority of stimuli encountered in everyday life evoke a unique space-time pattern of activity which is projected onto the central nervous system. Here the impulse pattern is first integrated with other incoming impulse patterns. The resulting pattern either increases, decreases, or has no effect on the excitatory state of the neurons to which these impulses are conveyed. The result is usually to set up yet another impulse pattern, which is projected to yet another set of sensory cells where further analysis ensues until at last the impulses are perceived as a sensation localized in the skin. The pattern on its way to the brain may become dissipated or transformed at each relay station, the degree of transformation depending upon the excitatory state of the station and the number of sensory impulses which converge upon it at a given time. There are no groups of specially modified terminals in the skin reporting by private lines the local state in respect of four clear-cut modalities. On the contrary, the amount of information available from the periphery is far more complex and varied. The particular information which dictates activity can be divided into four sensory modalities, but this selection is made in the central nervous system as the result of learning. As everyone knows, pain is not a single entity, but acts as a warning signal. It ordinarily follows when an unusually large and prolonged series of impulses from the skin or sensory relay station converge onto the circuits responsible for conscious experience. Warmth and cold can be regarded as preliminary warnings, informing the organism of impending danger. Touch evoked from diffuse endings, such as that produced by an insect crawling over the skin, can also be regarded as a warning signal which alerts the organism against a possible bite.

The arrangement of the nerves and their terminations in the skin of amphioxus resembles that in the human cornea. Moreover, the sensory functions of the skin in these animals appear analogous to that of the cornea. Touch, warmth, cold, and injurious stimuli all cause different reactions, but each can be interpreted as a response designed to avoid danger. *See* also NERVOUS SYSTEM; PAIN; SENSATION; TOUCH. (A. G. M. W.)

SKIN DIVING, diving and swimming underwater at considerable depth without the use of diving apparatus, is the most ancient diving technique and undoubtedly has been practised since the time man learned to swim. Although by strict definition the term skin diving applies only to "natural," or "free," diving, that is, without the use of any underwater breathing apparatus, in general use it also encompasses the closely related sports of diving with self-contained underwater breathing apparatus (SCUBA) and spearfishing. Skin diving is employed by pearl and sponge divers in many parts of the world and skin divers and SCUBA divers are engaged in commercial enterprises, such as underwater construction and salvage, and in scientific exploration of all kinds including oceanography, ichthyology, and archaeology. But the greatest popular interest is in diving as a sport.

The sport was first widely publicized in the 1930s with the publication of Guy Gilpatric's humorous book, *The Compleat Goggler*. In the warm waters off the coasts of southern California and in the Caribbean and the Mediterranean, pioneer skin divers, equipped only with waterproof goggles and a crude hand spear, and holding their breath while swimming underwater, began hunting fish and searching for mollusks and crustaceans. Later, a face mask, giving clearer underwater vision, replaced the goggles. Next came the snorkel, a short J-shaped tube, equipped with a mouthpiece, permitting a diver to swim or float on the surface and breathe while his face was in the water. Swimmers confined to the surface and using their masks for observation are called "snorklers." At the same time swim fins, or "flippers," shaped like duck feet, enabled even mediocre swimmers to swim effortlessly on the surface, and the dive became easier with quicker propulsion down from and back to the surface. Later still 1–2 lb. (450–900 g.) of lead attached to the belt helped journeys into depths of over 30 ft. (9 m.) by canceling the buoyancy of the human body without in any way impeding the rise to the surface. These aids brought skin diving within the ability of more people, and its popularity was greatly increased. But the lack of adequate underwater breathing equipment, or any protection against cold water, limited the sport to a handful of hardy swimmers, and confined its practice to warm southern waters.

With this simple equipment, the early skin divers learned to catch lobsters, shellfish, and octopus with their bare hands, and to stalk and spear fish in their own element. They also learned to explore underwater reefs and coral formations, archaeological remains and the hulks of sunken ships.

The sport continued to attract adherents in the 1940s but the mass invasion of the underwater world came after World War II in the 1950s. Publicity given to frogmen (*q.v.*) of underwater demolition teams, plus tremendous advances in skin-diving equipment, brought thousands of new converts to the sport, and its popularity spread around the world. Also aiding the rapid spread

of the sport were motion pictures such as *The Silent World* and television programs such as *Sea Hunt*.

A World Underwater Federation was formed at Monaco in 1959; the national diving federations represented were Belgium, Brazil, France, Great Britain, Greece, Italy, Malta, Monaco, the Netherlands, Poland, Portugal, Spain, Switzerland, the United States, West Germany, and Yugoslavia. Skin diving clubs were formed in Europe in the 1930s and the first clubs in the U.S., such as the San Diego Bottom Scratchers and the Los Angeles Neptunes, were formed in the 1940s. By the 1960s there were 1,250 organized diving clubs in the U.S. and Canada, including the Dusty Divers in New Mexico, and there were 50 or more clubs in Great Britain. There is no settlement or town of any size on the Mediterranean or Australian coasts without a club and the sport can be considered worldwide.

Development of SCUBA and Other Equipment.—With self-contained equipment the breathing gas is carried in tanks strapped to the diver's body, so the diver is independent of a supply of air or oxygen from the surface and is free to move about without impeding hoselines. The equipment falls into two categories: open-circuit and closed-circuit. While elementary versions of both systems were developed before 1880, the closed-circuit was refined for military applications during World War II. The first popular open-circuit SCUBA was developed by the French Navy, and in 1942 Comdr. J. Y. Cousteau and E. Gagnan took out the first patent for the "Aqua-Lung," a trade name that has often been applied erroneously to all SCUBA. Open-circuit units consist of an air reservoir of from one to three cylinders charged with the breathing mixture (usually compressed air) to a pressure of from 120 to 200 atm., and a demand regulator which feeds air through a hose and mouthpiece to the diver at ambient pressure when he inhales. While SCUBA generally is inadvisable for dives deeper than 130 ft. (40 m.) descents to much greater depths have been made by free divers. Since a human being labours under several physiological handicaps at depth, SCUBA divers should be trained and should not dive alone.

RUSS KINNE—PHOTO RESEARCHERS, INC

FULLY EQUIPPED OPEN-CIRCUIT SCUBA DIVER

The closed-circuit SCUBA (also called oxygen rebreathers or regenerative systems) consist essentially of three parts: (1) a relatively small steel cylinder charged with the breathing gas (usually pure oxygen) to a pressure of from 120 to 200 atm.; (2) a canister of soda lime or other carbon dioxide absorbent into which exhaled gas passes for removal of carbon dioxide; and (3) a breathing bag which acts as a reservoir for oxygen at ambient pressure between the cylinder and inhaling hose. Closed-circuit systems using pure oxygen are limited in depth to 30 ft. (9 m.). Prolonged respiration of a pure oxygen atmosphere at greater pressure ultimately results in convulsion and unconsciousness. Closed-circuit units are suitable for use only by specially trained and experienced divers. Closed-circuit divers have military uses, since they cannot be traced from the surface. They are used for prolonged work only in shallow water, to avoid subjecting the diver to "the bends" (*see* DIVING APPARATUS: *Effects of Air Pressure on the Diver*).

Other than the breathing apparatus, equipment used in SCUBA diving is identical to that required for skin diving. Further accessories include a weight-belt, a depth gauge and wrist watch (both mandatory in deep SCUBA diving), knife, compass, and self-inflating rescue device. (*See* also DIVING APPARATUS.)

At about the same time SCUBA was introduced, permitting extended submersions at greater depths and tremendously increasing the scope of diving, an adaptation of the rubber cold water suits used by navy frogmen was perfected, which permitted skin divers to stay warm and dry while submerged. These "dry" suits permitted skin diving in northern waters and beneath the ice of the Arctic. Later they were replaced by the more practical "wet" type foam rubber suits, which were less cumbersome and gave fewer problems to a diver. The diver's time in the water is still limited, however, by chill of the water.

Underwater Activities.—The mobility and simplicity of SCUBA opened a whole new world of underwater occupations, avocations, sports, and hobbies. SCUBA equipment can easily be transported into remote areas out of reach of conventional deep sea divers. Free swimming underwater, with no connecting lines to the surface, permits divers to work from shore, in shallow turbulent water and over extremely rough terrain.

One of the results was a rapid development of underwater photography. Equipped with pressure-proof still and motion-picture cameras, skin and SCUBA divers record the mysteries of underwater jungles, the colourful beauty of submarine coral gardens, and the excitement of exotic, little-known marine life. Conrad Limbaugh, skin diving scientist for Scripps Institution of Oceanography at La Jolla, Calif., used his camera to record damage to marine habitat from pollution. He also recorded the existence of fish cleaning stations, which large fish visit to be picked clean of skin parasites by smaller fish and other animals in a process called cleaning symbiosis. Cousteau used artificial lighting at great depths to record on film the brilliant colours of deep water marine life which cannot be seen with natural light. Dimitri Rebikoff of France synchronized powerful stroboscopic lights with an underwater motion-picture camera, which enabled him to film the living, moving colour of the depths. Water filters the colour out of sunlight, and below 52 ft. (16 m.) only blues and greens can normally be seen. In the early 1960s Cousteau pioneered the building of underwater stations to which divers can return between dives. By undergoing the decompression process only once just before the final return to the surface (sometimes after several weeks) Cousteau's divers increased their useful time under water from a maximum of about one hour a day to many hours.

SCUBA divers are engaged in underwater gold mining, tapping deep water rivers and streams in the Mother Lode country of the famous California gold rush of 1849. They are searching the hulks of ancient wrecks for sunken treasure and artifacts in all of the oceans and inland waters of the world. Few of their treasure hunts have resulted in quantities of gold, silver, or jewelry, but their discoveries of archaeological and historical significance have been of immeasurable value. Artifacts have been recovered from ancient wrecks in all waters of the world. Bronze Age artifacts recovered from a wreck off Cape Gelidonya, Turk., placed its age in the neighbourhood of 3,300 years, for example, and skin divers probing the bottom of Guatemala's Lake Anatitlán discovered sacrificial offerings of an ancient race of Maya Indians. In other areas of interest, skin diving scientists have discovered rivers of flowing sand on the ocean floor off Cape San Lucas, Mex., and stalagmites and the fossils of prehistoric human and animal bones at the bottom of Florida's Silver Springs.

The impact of skin and SCUBA diving upon the ecology of marine life has yet to be determined, but in some areas conservationists are taking precautions to preserve the natural beauty of submarine gardens by setting aside areas as marine reserves from which no plant or animal life may be taken. Such an area is the Pennekamp Coral Reef preserve, off Florida, which was set aside in 1960 to protect the natural beauty of the coral formations there. (P. R. GL.; L. V. B.)

Spearfishing.—The greatest single underwater sports attraction remains underwater hunting or spearfishing. The sport is of relatively recent origin. It required the invention of a device to extend the diver's range of vision underwater, and waterproof goggles (later replaced by face masks) did not appear until the early 1930s. As mentioned above, the sport was publicized by Guy Gilpatric. From this late start it spread rapidly throughout the world.

The arsenal of underwater weapons ranges from the simple

band spear to guns capable of penetrating the largest fish. The simplest weapon is the Hawaiian sling, a hollow wooden tube with an elastic loop at one end. The shaft, which is tipped by one of a variety of spearheads, is drawn through the tube and pulled back, stretching the loop. When released, the shaft is propelled forward. In the mid 1930s, Alec Kramarenko was granted a patent on an underwater gun in which the spear was propelled by a compressed spring. Shortly thereafter appeared a propulsion type gun invented by a Frenchman, Maxime Forlot and the popular spear gun propelled by a rubber elastic band designed by his compatriot, Georges Beuchat.

The foregoing are rifle-type weapons in which the spear either travels through a long barrel or is guided along its upper surface. In all cases, the spear shaft is released by a trigger mechanism. Early guns and carbon dioxide and compressed air types have a line attached to the shaft making it easier to retrieve. On strike, the line holds the quarry securely. A pneumatic air gun was invented in 1956 by Juan Vilarrubis of Spain and became popular because of its accuracy, power, and simplicity of operation. The targets include man-eating sharks, vicious barracuda and huge fish weighing several hundred pounds, as well as the ordinary game prized by fishermen everywhere. In most cases, stalking and shooting his quarry underwater is only the beginning of a skin diver's battle. After a fish is hit, it must be held on a harpoon line and landed. With large fish this may mean an underwater "ride" as the diver is towed through the water.

Underwater spearfishing is so popular among diving clubs that local, national, and international competitions are held each year. Local champions compete for the national championship and the privilege of representing their country in international competition, where world championships are determined. The competitions do not permit the use of SCUBA, and the contestants dive while holding their breath. Champions such as Jim Christiansen and Terry Lentz of the United States, Claudio Ripa of Italy, and Bruno Hermany of Brazil proved divers could hold their breath more than three minutes and work at depths exceeding 100 ft. In 1960 Enzo Majorca of Italy set a record depth for free diving. Holding his breath, and diving in the Mediterranean, he reached the depth of 51 m. (approximately 170 ft.).

SKIN GRAFTING: *see* Burns; Plastic Surgery; Transplants, Tissue and Organ.

SKINNER, OTIS (1858–1942), U.S. actor, who played hundreds of roles in all parts of the world in a career extending over more than 60 years, was born in Cambridge, Mass., June 28, 1858, the son of a minister. His first stage appearance was at the Philadelphia Museum in 1877 in *Woodleigh*. After two years in the stock company at the Walnut Street Theatre in Philadelphia, Skinner made his New York debut at Niblo's Gardens, Sept. 4, 1879, in *The Enchantment*. During the next five years he developed a classical repertory and a successful acting style, first with Edwin Booth, at Booth's theatre, and then, for three years, with Lawrence Barrett. In 1884 he joined Augustin Daly's company at Daly's theatre, remaining with it for four years. He made his London debut in 1886 with Daly's company, playing at the Strand Theatre. After two years with the Booth-Modjeska company, he became, in 1892, leading man opposite Helena Modjeska. In 1903 he starred with Ada Rehan. In addition to his Shakespearean roles, Skinner's chief successes were in *Kismet*, which he played between 1911 and 1914, and *Blood and Sand* (1921), in which he played the matador, Juan Gallardo. Skinner was active in the theatre until his death on Jan. 4, 1942. He was the author of *Footlights and Spotlights* (1924) and *Mad Folk of the Theatre* (1928).

Skinner's daughter, Cornelia Otis Skinner (1901–), actress and monologist, was also the author of many sketches, a play, *Captain Fury*, verse, and light essays. (S. W. H.)

SKINNER'S CASE, the name usually given to the celebrated dispute between the House of Lords and the House of Commons over the question of the original jurisdiction of the former house in civil suits.

In 1668 a London merchant named Thomas Skinner presented a petition to Charles II asserting that he could not obtain any redress against the East India Company, which, he asserted, had injured his property. The case was referred to the House of Lords, and Skinner obtained a verdict for £5,000. The company complained to the House of Commons which declared that the proceedings in the other house were illegal. The Lords defended their action, and after two conferences between the houses had produced no result the Commons ordered Skinner to be put in prison on a charge of breach of privilege; to this the Lords replied by fining and imprisoning Sir Samuel Barnardiston, the chairman of the company. Then for about a year the dispute slumbered, but it was renewed in 1669, when Charles II advised the two houses to stop all proceedings and to erase all mention of the case from their records. This was done and since this time the House of Lords has tacitly abandoned all claim to original jurisdiction in civil suits.

SKIPTON, a market town and urban district in the Skipton parliamentary division of the West Riding of Yorkshire, Eng., on the Leeds and Liverpool canal, 43 mi. E. of York by road. Pop. (1961) 13,008.

Lying in the hilly district of the upper valley of the Aire where it is joined by the Eller Beck from the north, it is the nodal town of the Craven gaps, the lowest ways through the Pennines between Trent and Tyne, and so has become an important route centre and the principal market town of Craven. Weekly sales of cattle and sheep take place.

During the Middle Ages the Craven gaps were the chief routes through the Pennines along which the Angles, and later the Danes, moved westward, and Skipton was the capital of Craven. At the Norman Conquest, it became part of the possessions of Earl Edwin and was granted to Robert de Romille, who built the castle in the 11th century. It was taken by the parliamentary forces in 1645 after a three-year siege, partly demolished in 1648, restored by Lady Anne Clifford in 1657–58, and now consists chiefly of the gateway with its two round towers and an original Norman arch to the inner court. In the grounds are the remains of the castle chapel. The parish church of the Holy Trinity, mainly Perpendicular, was also partly destroyed during the Great Rebellion but has been restored. The grammar school was founded in 1548.

There are rayon and silk factories in the town and a large limestone quarry nearby.

SKOBELEV, MIKHAIL DIMITRIEVICH (1843–1882), Russian army officer, one of the conquerors of Turkistan and a prominent commander also in the Russo-Turkish War of 1877–78, was born in St. Petersburg, on Sept. 29 (new style; 17, old style), 1843. After graduating from the General Staff Academy in St. Petersburg, he was sent to Tashkent in 1868. With the exception of two years' service in the Caucasus, he remained in Turkistan until 1877. In 1873 he took part in the expedition against Khiva, commanding the advance guard of Col. N. P. Lomakin's column, which marched on the khanate from the Mangyshlak Peninsula on the Caspian Sea. In 1875–76 he held a command in Gen. K. P. Kaufmann's expedition against Kokand, earning promotion to the rank of major general and appointment as the first Russian governor of Fergana.

When war broke out between Russia and Turkey, Skobelev was transferred to the European front. He captured the bridge over the Seret at Barboşi in April 1877 and crossed the Danube in June. He commanded the Caucasian Cossack brigade in the attack of the Green Hills at the Second Battle of Pleven (Plevna). He captured Lovcha on Sept. 3, and distinguished himself again in the Third Battle of Pleven. In command of the 16th division, he took part in the investment of Pleven and also in the fight of Dec. 10, when Osman Pasha surrendered. In January 1878 he crossed the Balkans in a severe snowstorm, defeating the Turks near Shipka Pass and capturing 30,000 men and 90 guns. Later he captured Edirne and San Stefano. Dressed in a white uniform and mounted on a white horse, and always in the midst of the battle he was known by his soldiers as the "White General."

Skobelev subsequently returned to Turkistan. He captured Göktepe on Jan. 24, 1881, and, after slaughtering about 8,000 people, reduced the Akhal-Tekke country to submission. He was advancing on Ashkhabad when he was recalled and given the command of the Minsk Army Corps. In the last period of his short life he was active in politics. He made speeches in Paris and in Moscow at the beginning of 1882 in favour of a militant Pan-Slavism, predicting inevitable conflict between German and Slav. He was at once recalled to St. Petersburg. He died suddenly of heart disease in Moscow on July 7 (N.S.; June 25, O.S.), 1882.

ŠKODA, EMIL VON (1839–1900), Czech engineer and industrialist who founded one of the most important industrial complexes of Europe, including the Škoda armament works, was born at Cheb (Eger) on Nov. 19, 1839. He was the nephew of Josef Škoda, a celebrated professor of medicine in the University of Vienna. Škoda studied engineering in Germany and in 1866 accepted the position of chief engineer in a small machine factory in Plzeň (Pilsen) that belonged to Count Ernst von Waldstein. Three years later Škoda himself bought this factory, which at the time employed only 33 people. He expanded the undertaking at a great pace in the 1880s, building a railway connection with the main Vienna–Cheb line in 1886, and finally adding an armaments factory in 1890. In 1899 he founded a Škoda works company, under his own direction. At the time of his death on Aug. 8, 1900, the Škoda factories employed some 4,000 workers. (E. Wi.)

SKOKIE, a residential and light industrial village of Cook County, in northeastern Illinois, U.S., is on the northern edge of Chicago and west of Evanston. Called Niles Center until 1940, Skokie was first settled in 1834 and attracted a colony of settlers from Luxembourg. By the time of its incorporation in 1888 the trading centre was known primarily for its greenhouse industry, started during the previous decade.

In the late 1920s a development boom occurred in the community following the extension of service by the Chicago and North Western and the Chicago, North Shore and Milwaukee railroads. The depression of the 1930s halted the growth of the village but World War II began a great influx of industry. The community nevertheless retained much of its earlier residential character, and residential and commercial building (including extensive shopping facilities) increased sharply in the postwar years. Between 1950 and 1964 the population increased from 14,832 to 67,865. (For comparative population figures *see* table in ILLINOIS: *Population.*)

The village adopted a council-manager form of government in 1957. (Ar. C. H.)

SKOPJE (Serbo-Croatian, SKOPLJE; Turkish, USKUB; Albanian, SHKUP; ancient, SCUPI and JUSTINIA PRIMA), the capital city of the Socialist Republic of Macedonia, Yugos.; an episcopal see for both the Serbian Orthodox and Roman Catholic churches; and one of two centres of the Muslim administrative and supervisory body for Yugoslavia.

The city was almost entirely destroyed by an earthquake on July 26, 1963. It stood on the Vardar river in the midst of mountainous country, 210 mi. S.E. of Belgrade. Pop. (1961) 171,893, of mixed origin. The old part of the city was on a slope on the left bank overlooked by an ancient fortress with, north of it, a Roman aqueduct. Other old buildings were the medieval Turkish Kursumlihan (caravansary) and the mosques of Sultan Murad II (1430) and the ghazi ("warrior") Isay Bey (1476).

Modern Skopje, begun in the early 19th century, developed with the construction of the Belgrade-Salonika railway through the town; but most building was done after World War II. The old city was linked with the new part on the right bank, across the old bridge. Outstanding of the modern buildings were the Macedonian parliament, the university (founded 1946) and the bishops' palaces. Skopje's position made it an important road junction for the whole Balkan peninsula. Industries included textiles, steel, ceramics, chemicals and glass; local metalliferous ores are mined. It was long a centre of silver filigree work and other handicrafts. Three miles southwest is the monastery of St. Panteleimon (1164) with fine frescoes.

Ancient Scupi, a city of Moesia, became the capital of Dardania under the Roman emperor Diocletian in the 4th century A.D. Justinian I rebuilt it after its destruction by an earthquake in 518. The Serbs first seized Skopje in 1189; their self-proclaimed emperor Stephen Dushan was crowned there in 1346. In 1392 the Turks made it their capital. It declined during the 18th century but revived during the 19th, especially with the coming of the railway at mid-century. By the London and Bucharest treaties of 1913 it was incorporated into Serbia; and in 1918 became part of the new state of Yugoslavia. During World War II the Germans occupied it in April 1941 and it was then garrisoned by Bulgarian troops. In 1945 it was made capital of Macedonia in the Federal People's Republic of Yugoslavia.

The earthquake of 1963 killed more than 1,000 of Skopje's inhabitants and rendered 120,000 of them homeless. Relief in cash and in kind, including medical, engineering and building teams and supplies, was immediately dispatched from many countries. (V. Dr.)

SKUA, a rapacious sea bird, *Catharacta skua*, of the family Stercoraridae, related to gulls. (Closely related are the three species of jaegers [*q.v.*], sometimes grouped with the skua in a common genus, *Stercorarius*, in which event all are referred to as skuas.)

The great skua, or bonxie (*C. s. skua*), nests on the ground of tundra from the Faeroes, Shetland and Orkney Islands north-

ERIC HOSKING

SKUA (CATHARACTA SKUA) AT NEST

ward to Iceland. In the southern hemisphere distinct geographic races inhabit the tip of South America, various subantarctic islands and the Antarctic continent. The species is thus "bipolar," a unique phenomenon among birds. The southernmost form *C. s. mccormicki*, is pale-coloured and strongly distinct from the others. It has been encountered far in the interior of the icy continent, closer to the pole than any other animal.

Skuas lay two eggs but usually devour one of the chicks soon after it hatches. They have a hawklike plumage, with a conspicuous whitish patch at the base of the wing quills, and talons on their webbed feet. In flight they suggest a small eagle rather than a gull. Their beating flight is surprisingly strong, a fact hardly evident until they are seen to overtake longer-winged and supposedly swifter species.

On breeding grounds skuas are fearless of man. They are the scourge of neighbouring birds and (in the north) also of lemmings. The southern races prey upon petrels and the eggs and chicks of penguins. At sea, in the nonbreeding period, they capture living organisms for themselves but also pursue and harry other sea fowl, forcing them to disgorge their catches. (R. C. Mu.)

SKULL. The skull comprises the bony structures of the head. Its main parts are the cranium, or brain case (eight bones),

and the facial skeleton (14 bones, including the upper and lower jaws). The function of the skull, apart from providing for the suspension of the jaws, is to protect the brain and the organs of special sense: the nose, eyes, and ears. The skull is poised on the first, or atlas, vertebra in a manner which permits nodding movements of the head. Rotation of the head is carried out by movement of the ringlike atlas around the peglike odontoid process of the second, or axis, vertebra.

The following account of the human skull considers its structure, the infant skull, evolution of the skull, and the skull in anthropology.

Structure.—The adult skull has a dome-shaped brain case composed of the frontal bone over the forehead; the parietals at the top and upper sides; the temporals and sphenoids at the lower sides; and the occipital at the back (*see* fig. 1 and 2). The bones of the cranial vault are joined to each other at the sutures, which are actually fibrous joints and are shown in the figures as serrated lines between the bones. They serve in the young skull to join the bones together while allowing a slight degree of movement between them—an arrangement conferring some elasticity on the skull. This elasticity, together with the generally convex shape of the bones, enables the cranium to withstand blows of considerable force. The sutures become progressively and slowly obliterated by the formation of a bony union between the individual bones, this process beginning in the young adult skull and being advanced by the time of middle age.

Frontal Aspect.—The human forehead (*see* fig. 1) is smooth and almost vertical; it lacks the well-developed brow ridge of the great apes. The orbits, or eye sockets, roughly quadrilateral in shape, face forward and slightly outward; this position of the eyes in man is of great importance since it permits an overlap of the visual fields that makes true stereoscopic vision possible. This overlap is also favoured by the great reduction of the nose area (corresponding to the projecting snout of other animals, which causes their eyes to be placed far over on the sides of the head). The orbits of the human skull are bounded at the outer edge by the zygomatic bone. The orbital cavities are conical in shape and taper as they are traced deep into the skull. At the apex of the orbit are several holes through which the nerves to the eye and to the eye muscles gain entrance to the orbit. The bones forming the inner walls of the orbit are thin and delicate; those of the roof and floor are more massive.

In the centre of the facial skeleton is the external orifice of the nasal cavities. The bridge of the nose is made by the flat nasal bones and the rest of the nasal orifice is bounded by the maxillary bones (*see* below). The external projection of the nose on the face of a living person is due almost entirely to cartilaginous structures that are not properly a part of the skull. The greater part of the nasal cavities lies deeply buried within the skull. On the outer wall of each nasal cavity are two scrolls of bone, the turbinate bones; in life the scrolls are covered by a thick mucous membrane which is believed to assist in warming the incoming air before it passes into the lungs. In the midline between the nasal cavities is the bony nasal septum (partition).

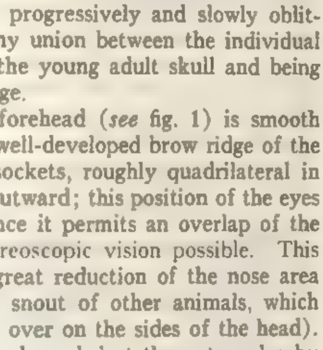

FIG. 1.—HUMAN SKULL FROM FRONT

The maxillary bones (one maxilla on either side) make up the main mass of the upper jaw and carry 16 teeth in the adult. Internally the maxillary bones are hollowed out to form the maxillary sinuses, which are lined with mucous membrane continuous with that of the nose.

The mandible is the single large bone making up the lower jaw; like the maxillaries it bears 16 teeth. Holes in the frontal bone, maxillary bones, and mandible provide for the exit of branches of the trigeminal nerve passing to the skin of the face.

Lateral Aspect.—At the outer margin of the orbit the zygomatic bone sends backward a prolongation which meets a similar process of the temporal bone to form the zygomatic arch (*see* fig. 2). The space between the zygomatic arch and the side of the brain case allows the powerful temporalis muscle to gain attachment to the mandible; its function is to close the jaws. At the posterior end of the zygomatic arch is the external auditory canal, or ear hole; its walls are made up chiefly of a tubular bone, the tympanic. A slender, pointed bony structure projecting down from the base of the skull from a point just behind the tympanic bone is the styloid process. A fibrous band, the stylohyoid ligament (indicated by dotted lines in fig. 2), is found in the living person attached above to the tip of the styloid process and below to the hyoid bone (*see* below, *Evolution of the Skull*). Behind the external auditory canal is a bulging area of bone called the mastoid process. It is a typical feature of the human skull and contains many small cavities, or air cells, continuous with the cavity of the middle ear. These cells are readily infected and may give rise to mastoiditis (*q.v.*).

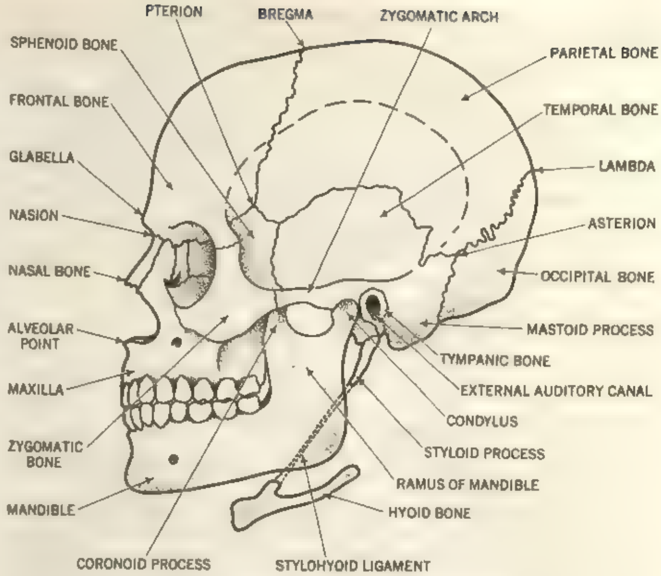

FIG. 2.—HUMAN SKULL FROM LEFT SIDE

The shape of the mandible can be recognized more clearly from the side. It consists of a horizontal body which carries the teeth on its upper surface and, posteriorly, an ascending portion, the ramus. At the upper margin of the ramus are two prominences, one in front called the coronoid process and one farther back called the condylus. The condylus is rounded and coated with cartilage in life. It fits into a depression in the undersurface of the temporal bone to form with it a movable joint, the temporomandibular joint, which permits opening and closing of the mouth and also side to side movement as in chewing.

Of special note is the pterion, the point of juncture of the frontal, parietal, and sphenoid bones. The conformation of the sutures at this point is very distinctive in the human skull and is of interest when comparing the human skull with that of closely related species such as the anthropoid apes. From the surgeon's standpoint the pterion is an important locus, since it overlies the large middle meningeal artery inside the skull; this artery is frequently torn as a result of a blow on the side of the head.

Sagittal Aspect.—A vertical section through the middle of the skull (fig. 3) shows the relative thinness of the bones of the vault of the skull overlying the brain. In a young person these bones consist of three layers, an inner and outer table of compact bone with a middle layer of bone marrow. The latter layer, called the diploe, disappears with advancing age. When a blow is administered to the skull the inner table is apt to be more severely damaged than the outer table and sharp slivers of bone may be driven into the brain. Moreover, since the dome of the skull is somewhat elastic, at least in the young person, the force of the blow may be transmitted around to the base of the skull, producing a fracture there.

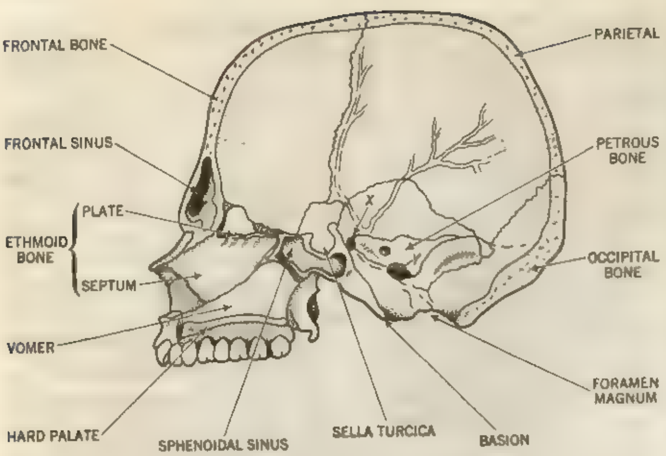

FIG. 3.—INTERIOR OF HUMAN SKULL IN VERTICAL SECTION

The base of the skull, from front to back, is made up of basal portions of the frontal, ethmoid, sphenoid, temporal, and occipital bones. The base supports the weight of the brain, which is protected by fluid-filled spaces between it and the base of the skull. The sectional view also shows the large air sinuses within the frontal bone above the nasal cavity and within the body of the sphenoid. These sinuses are continuous with the nasal cavity. Behind the frontal bone is the ethmoid bone. In the floor of the skull the ethmoid forms a perforated plate through which pass the nerves to the nose. It also has an upward projection, the crista galli, and a downward projection which forms the upper part of the nasal septum. The upper surface of the sphenoid bone is hollowed out to form the sella turcica in which the pituitary gland lies. This important gland, on which the proper functioning of all other endocrine glands depends, is thus situated in an invulnerable place in the skull; its inaccessibility makes a surgical approach very difficult.

A massive portion of the temporal bone in the floor of the skull, called the petrous bone, is the hardest bone in the body. It houses the internal mechanisms of the ear. On the inner side of the petrous bone is a hole for the passage of the auditory nerve. The medulla oblongata (basal portion of the brain) and the spinal cord are continuous with each other through the foramen magnum, the large hole in the base of the skull. The great internal carotid artery gains access to the skull at the point indicated in fig. 3 by X and the great internal jugular vein leaves the skull at the point indicated by Y.

It has been noted that the ethmoid bone takes part in the formation of the nasal septum. The rest of the septum consists of the vomer and the maxillary bones. The hard palate in the roof of the mouth is made up of the maxillary bones and the palatine bones.

The Infant Skull.—The skull of a newborn baby (*see* fig. 4) shows clearly the multiple bones in the brain case. At this stage

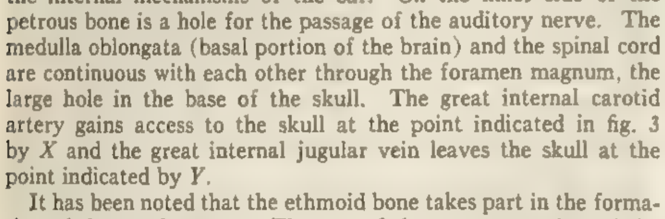

FIG. 4.—SKULL OF NEWBORN INFANT FROM LEFT SIDE

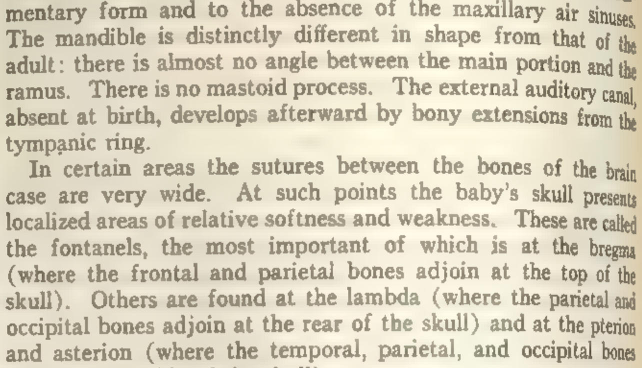
the bones are widely separated by sutures which thus confer great flexibility on the skull and permit overriding of the bones upon each other during the process of birth. The facial skeleton is quite small by comparison with the brain case. The maxillary bones are very small, due to the absence of teeth except in rudimentary form and to the absence of the maxillary air sinuses. The mandible is distinctly different in shape from that of the adult: there is almost no angle between the main portion and the ramus. There is no mastoid process. The external auditory canal, absent at birth, develops afterward by bony extensions from the tympanic ring.

In certain areas the sutures between the bones of the brain case are very wide. At such points the baby's skull presents localized areas of relative softness and weakness. These are called the fontanels, the most important of which is at the bregma (where the frontal and parietal bones adjoin at the top of the skull). Others are found at the lambda (where the parietal and occipital bones adjoin at the rear of the skull) and at the pterion and asterion (where the temporal, parietal, and occipital bones adjoin on the side of the skull).

Evolution of the Skull.—The head of a hypothetical animal which may have preceded the vertebrates is illustrated in fig. 5A. The head already possesses a well-developed brain, two nasal pits, two eyes, and two ears, the latter being concerned only with balance. Instead of a bony vertebral column there is a semirigid rod called the notochord which traverses the full length of the animal below the spinal cord and ends in front just behind the pituitary gland (fig. 5A).

At a later stage in the evolution of the skull (fig. 5B) certain



AFTER "HISTORY OF THE HUMAN BODY" BY H. H. WILDER, HENRY HOLT & CO., N.Y.

FIG. 5.—DIAGRAMS SHOWING THREE STAGES IN THE EVOLUTION OF THE SKULL: (A) HEAD OF A HYPOTHETICAL PREVERTEBRATE ANIMAL; (B) LATER STAGE OF ANIMAL WITH VERTEBRAL COLUMN; AND (C) VERTEBRATE WITH PRIMITIVE SKULL

additions are made to the head. Cartilaginous capsules partially invest the nasal pits and the eyes and completely invest the ears. The need for added rigidity is met by the development of two rods of cartilage on either side, the cranial bars (trabeculae) in front and the parachordal cartilages at the back of the head.

At a still later stage (fig. 5C) a general consolidation of the cartilaginous elements of the primitive skull takes place by the fusion of the cranial bars and the parachordal cartilages into a single cartilaginous cranial base and the fusion of this in turn with each of the sense-organ capsules. Further extensions of the cartilaginous skull also take place above the brain.

This sequence of events in the evolution of the skull can be deduced with a fair degree of confidence since it is essentially what takes place in the development of the embryos of all vertebrates, including man. Speculation about the skull becomes fact with the conditions present in the skulls of a large group of fish having cartilaginous skeletons, the elasmobranchs. These primitive fish, which include the sharks and rays, have skulls essentially similar to that depicted in fig. 5C. The next stage in the evolution of the skull is the appearance of added protection for the head in the form of bony plates. The living primitive fish of the ganoid group, which includes the sturgeons and gars, have this armour plating over the head and some of the body. The bony plates of the skull are actually developed from the connective tissues of the skin and are called dermal bones. These bones be-

come extremely numerous in the bony fish known as teleosts, the group which includes most of the ordinary fish. A striking feature of the dermal bones in all vertebrates above the fish is their development not on the surface of the head but deep in the connective tissues under the skin. This is the way they develop in the human embryo.

The same evolutionary sequence is also marked by important changes in the cartilaginous skull lying inside the outer skull of dermal bones. Centres of bone formation appear within the cranial base and the sense-organ capsules and convert them into solid bone. This change is foreshadowed in the elasmobranchs and is well advanced in the teleosts. At the same time there are varying degrees of fusion between the dermal bones and between these and the underlying cranial base and the sense-organ capsules. In essence this completes the story of the evolution of the skull. There is, however, an infinite variety in the detailed arrangements of the elements of the skull in different groups of animals.

There remains to be considered the so-called visceral skeleton. This includes the jaws and the hyoid apparatus (*see* fig. 2). In the fish the gills are supported by cartilaginous bars, the branchial, or visceral, arches. The upper jaw consists of a plate of cartilage, the palatoquadrate bar; the lower jaw consists of Meckel's cartilage. The jaw joint is formed between the quadrate and the articular cartilages, which are merely the hind ends respectively of the palatoquadrate and Meckel's cartilages.

In the ganoids and teleosts new dermal bones are laid down around the cartilages of the jaws; the articular and quadrate cartilages continue to form the jaw joint. In higher vertebrates there are profound modifications in the visceral skeleton of the skull. A new joint is developed between the dermal lower jaw and the temporal bone. The quadrate and articular cartilages are thus no longer necessary. They do not disappear, however, but are apparently transformed into the small bones of the ear, the quadrate becoming the anvil bone (incus) and the articular becoming the hammer bone (malleus).

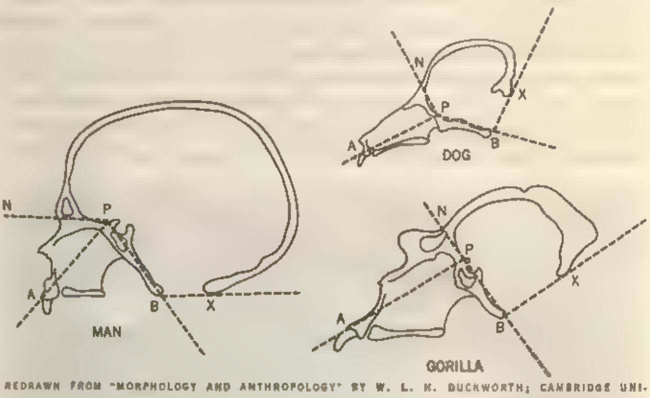
The remaining gill arches of the fish also become greatly modified in higher vertebrates with the disappearance of gills and the development of lungs. The second and third gill arches become transformed into the hyoid bone together with the styloid process and the stylohyoid ligament (*see* fig. 2). The stirrup bone (stapes) of the ear appears to be developed from the second arch. The remaining arches become modified in man as the cartilaginous framework of the larynx, or voice box.

The human skull, then, may be regarded as consisting essentially of an inner skull, very ancient from the evolutionary point of view, which includes the base of the skull and the sense-organ capsules; and an outer, more recent skull, made up of the so-called dermal bones. The dermal bones are typically found in the dome of the skull, the face, and the mandible. They have proved extremely plastic in adapting themselves to the enormous development of the brain that characterizes man.

The Skull in Anthropology.—The student of fossilized remains who wishes to establish their possible affinities with man must keep clearly in mind exactly what criteria make a skull typically human. Doing so necessitates a thorough knowledge of the many natural variations of the skull in different groups and races of mankind and in modern man's progenitors. (*See* RACES OF MANKIND; ANTHROPOLOGY, *Physical Anthropology.*) Some of the distinctly human features are reviewed below.

The capacity of the brain case is relatively and absolutely large in all known races. If the capacity is less than 1,350 cc. the skull is called microcephalic; if 1,350 to 1,450 cc., mesocephalic; and if over 1,450 cc., macrocephalic. Another characteristic feature of the human skull is the smooth, almost vertical forehead, lacking the pronounced brow ridges found in many apes and certain extinct forms of man. There is a marked concavity above the canine (cuspid) tooth in the upper jaw, the canine fossa, which is absent or is replaced by a convexity in apes and in extinct man. The mandible is characterized by a definite angle between the ramus and the horizontal portion. The condylus of the ramus is also typical. The bony prominence of the chin is a distinctive human trait, as is the absence of a shelf of bone at the back of the chin known as the simian shelf, found in all apes but generally absent in the mandible of early man. The mastoid and tympanic region and certain sutural areas, such as the pterion, also serve to distinguish the human from the anthropoid skull.

The human skull differs markedly from those of other animals in the way it is poised upon the vertebral column and in the proportions of the face. This is illustrated in fig. 6, where the skulls of man, gorilla, and dog are compared (cross-section views), certain planes of reference being indicated by dotted lines. The plane of the foramen magnum (BX) is horizontal in the human skull, slightly inclined to the horizontal in the gorilla, and almost vertical in the dog. This indicates that in man, who is truly an erect animal, the skull is perfectly balanced on the top of the spine. In the gorilla this is not so and powerful muscles are developed at the back of the neck to counterpoise the weight of the face with its massive jaws. In the dog, which walks on all fours, the skull is held at right angles to the axis of the spine (BX). Other angles, indicated in fig. 6, may be of value in establishing that a skull is not anthropoidal. The sphenethmoidal angle (NPB) is drawn by projecting a line (PN) forward in the plane of the ethmoid plate from a point just behind this plate known as the prosphenion (P) and another line (PB) from the latter point passing through the axis of the base of the skull to the front of the foramen magnum (B). The difference in this angle in the skulls of man, gorilla, and dog is striking. In man the plane of the ethmoid plate has been rotated downward and forward, a change associated with the enormous development of the frontal lobes of the brain. The sphenomaxillary angle (APB), determined by adding a line (PA) from the prosphenion to the alveolar point (A) just above the upper incisor teeth, indicates that there has been a striking reduction in the projection of the face, or snout area, in man together with some rotation of the maxillary area downward.



REDRAWN FROM "MORPHOLOGY AND ANTHROPOLOGY" BY W. L. H. DUCKWORTH; CAMBRIDGE UNIVERSITY PRESS

FIG. 6.—FACIAL ANGLES IN THE SKULLS OF MAN, DOG, AND GORILLA

Certain cranial indexes can be calculated from measurement of the diameters of the skull. Large calipers are used for this purpose. The length of the skull is the distance from the glabella (the midpoint between the brows; *see* fig. 2) and the most projecting point at the back of the head. The breadth of the skull is the distance between the most projecting points at the sides of the head, usually a little above and behind the ears. The cephalic index is the breadth × 100 divided by the length. An index of less than 75 means that the skull is long and narrow when seen from the top; such skulls are called dolichocephalic, and are typical of native Australians and the Kaffirs. An index of 75 to 80 means that the skull is nearly oval; such skulls are called mesaticephalic and are typical of Europeans and the Chinese. A skull having an index of over 80 is broad and short, and is called brachycephalic; such skulls are common among Mongolians and the Andaman Islanders. Other cranial indexes are the index of height and the gnathic, or alveolar, index. The former is calculated as the height of the skull from the basion (front of the foramen magnum; *see* fig. 3) to the bregma (*see* fig. 2) × 100 divided by the breadth. The latter is reckoned as the basialveolar length (from basion to alveolar point; *see* fig. 2 and point marked *A* in fig. 6) × 100 di-

vided by the basinasal length (from basion to nasion [root of the nose; *see* fig. 2]) and gives a measure of the degree of snout projection (prognathism).

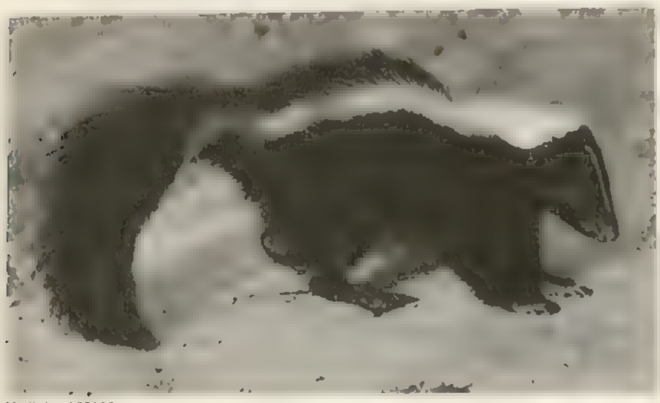
SKUNK, any of the several species of the weasel family (Mustelidae) noted for the offensive odour produced by glands on either side of the anal opening. The animal can eject the yellow, odoriferous liquid as far as 12 ft. Skunks, often called "polecats," belong to the subfamily Mephitinae and are exclusively American. The typical striped skunk (*Mephitis mephitis*) is cat-sized, squat, and bushy tailed; it has a shaggy, glossy black coat



JOHN H. GERARD

COMMON STRIPED SKUNK (MEPHITIS MEPHITIS)

marked by a white stripe (sometimes paired) extending from the base of the head to, and sometimes including, the tail. The striped and closely related hooded (*M. macroura*) skunks are found from central Canada to northern Mexico; other *Mephitis* species occur southward to Nicaragua. The smaller spotted skunk (*Spilogale putorius*), unlike other skunks, climbs well. Its black coat is marked with four to six white, sometimes broken stripes. Spotted skunks (including the *S. gracilis*, *S. pygmaea*, and *S. angustifrons*) occur over most of the United States southward to Costa Rica. The hog-nosed skunks (*Conepatus mesoleucus*, *C. leuconotus*, and others) occur from the southern United States into South America. Their pelage is black except for the white back and tail.

Skunks are omnivorous. They feed on small arthropods, mice, rats, eggs, birds, and plants; the several species show somewhat different food preferences. Skunks are calm, deliberate, amiable creatures seldom molested by other animals because of their repulsive scent. They usually amble along, rarely proceeding at a fast gait. Most skunks accept man's presence and will establish a den under a building as well as in natural sites like tree stumps, caves, rock outcroppings. In the striped skunk four to seven young are produced in the spring, about two months after mating.

When deodorized, skunks make delightful and affectionate pets. The pelt is of value commercially and is usually plucked and dyed to simulate more precious furs; hence skunks are both trapped and raised on fur farms. The scent is persistent and when treated is useful as a perfume base. (K. R. KN.)

SKUNK CABBAGE (*Symplocarpus foetidus*), a fleshy herbaceous plant of the arum family (Araceae), so called because of its fetid odour and large leaves, native to eastern North America and northeastern Asia.

The plant grows in swampy places and in very early spring (March or sometimes February) sends up from thick rootstocks grotesque, swollen, shell-like, purple-brown spathes, each enclosing many small flowers borne in a short thick cluster. These are soon followed by numerous ovate leaves, one to three feet long, and later by large globular masses of fleshy berries. The similar western, or yellow, skunk cabbage (*Lysichitum*) occurs in western North America.

SKY, surrounding space as seen above the horizon. From the surface of the earth it has the appearance of a great dome, low and rather flat. When clouds fully obscure the space beyond, the impression of flatness is accentuated. When unclouded, the dome seems closer to the observer at a point directly overhead. This article is concerned with the physics of colour and brightness in the sunlit sky of the earth. In the 1960s it was expected that the first extraterrestrial sky to be observed would be that seen from the surface of earth's moon (almost devoid of atmosphere, and differing substantially in appearance). For additional aspects of sky phenomena, *see* ASTRONOMY; AURORA POLARIS; HALO; METEOROLOGY; MIRAGE; RAINBOW; SPACE EXPLORATION; UNIDENTIFIED FLYING OBJECT (UFO); VAN ALLEN RADIATION BELTS.

Although subject to such variations as spectacular sunrises and sunsets, the characteristic colour of a cloudless sky on earth is dark blue at high elevations and pale blue at lower levels. Even when viewed from high altitudes, earth's sky appears brightest and whitest near the horizon (*see* ATMOSPHERE; CLOUD; HORIZON; TWILIGHT).

The colour of the sky is closely associated with polarization of light, arising from the electromagnetic nature of light waves. If oscillations in the electromagnetic wave are largest in one direction normal to the axis along which the light is propagating, the light is said to be polarized. Since people normally cannot distinguish such light from ordinary light in which the oscillations are equal in all transverse directions, special optical analyzers, usually incorporating sheet polarizers (*e.g.* Polaroid plates), are used to make the polarization visible. A polarizer blocks the transmission of oscillations in all directions except one. When a polarizer is rotated between the observer and the bluest part of the sky, the brightness of the sky as viewed through the polarizer will change. With brightness at minimum, rotation through 90° will increase intensity to a maximum that may be as much as four times brighter (*see* LIGHT: *Polarization and Electromagnetic Theory*).

Polarization of skylight was discovered by D. F. J. Arago (*q.v.*; 1809), who found that maximum polarization appears at right angles to the sun in the sun's vertical (the plane through the zenith and the sun). He also found in the vertical a point with vanishing polarization (the Arago neutral point) at an angular distance of 18° from the antisolar point. Another neutral point was discovered (1840) by J. Babinet in the vertical at an angular distance of about 18° above the sun. With a special arrangement to diminish glare near the sun, Sir David Brewster (*q.v.*) discovered a third neutral point in the vertical 18° below the sun.

The observed colour and polarization of light from a cloudless sky were once attributed to reflection of sunlight on hypothetical thin bubbles of water or other small particles (R. Clausius), or to transmission through a turbid medium (Tyndall effect). However, the first effective effort to relate and explain colour and polarization was by Lord Rayleigh (1881) in his mathematical theory of light scattering by small dielectric particles (*see* LIGHT: *The Atomic Theory of Refraction*).

Rayleigh Theory of Primary Scattering.—Using J. C. Maxwell's equations of the electromagnetic field (*see* ELECTROMAGNETIC WAVES), Lord Rayleigh showed that a volume of matter (with dimensions negligible as compared with the wavelength of incident light, and with a dielectric constant slightly different from its environment) propagates its own electromagnetic waves. In other words, light falling on the small volume is reemitted (scattered) in all directions.

The amount of scattered light is larger for shorter (blue) wavelengths than for longer (red) ones. The intensity I of the scattered light is inversely proportional to the fourth power of the wavelength; $I \sim \lambda^{-4}$.

When the volume is illuminated by unpolarized light, the scattered light is polarized. The intensity $I\perp$ of the oscillations vibrating perpendicularly to the scattering plane (*i.e.*, to the plane containing the direction of the incident and of the scattered beam) is the same for all values of the scattering angle θ between the direction of the incident and scattered beam. The intensity $I\parallel$

of the oscillation vibrating in the scattering plane varies as $\cos^2 \theta$. Hence the degree of polarization P is given by

$$P = (I_\perp - I_\parallel)/(I_\perp + I_\parallel) = \sin^2 \theta/(1 + \cos^2 \theta) \quad (1)$$

Therefore in the forward and backward direction ($\theta = 0°, 180°$) the scattered light is unpolarized ($I_\perp = I_\parallel$), while at right angles to the incident light, the scattered light is completely polarized ($I_\parallel = 0$). Since the intensity $I = I_\perp + I_\parallel$, it varies with the scattering angle as $1 + \cos^2 \theta$. The distribution of the intensity is thus symmetrical to the principal directions $\theta = 0°, 180°$ and $\theta = 90°, 270°$.

After scattering, the incident parallel beam has lost all the energy scattered in all directions around the scattering volume. This attenuation is inversely proportional to the fourth power of the wavelength (λ^{-4}) of the incident light; blue light thus loses more energy than does red.

Since air molecules have negligible size with respect to the wavelengths of visible light, Rayleigh theory can be applied to a pure, molecular atmosphere. If sunlight were scattered by air molecules only once (primary scattering), skylight would exhibit the properties noted above. In locations where the atmosphere is relatively free of haze, dust, or industrial pollution, skylight measurements tend to approach those predicted by Rayleigh theory. For example, observations of the remarkably clear and dry atmosphere above Mt. Wilson in California led F. E. Fowle (1914) to conclude that scattering there is almost entirely the result of air molecules themselves. The deep blue colour is a function of the λ^{-4} dependence of skylight intensity on wavelength. The skylight is highly polarized, with maximum intensity perpendicular to the sun in the sun's vertical plane (as discovered by Arago).

Even for very clear air, however, the colour of the sky becomes whitish toward the horizon. The light at right angles to the sun at the sun's vertical is only partially polarized ($P = 75\%$). Furthermore, degree of polarization varies with wavelength; according to Rayleigh theory, as indicated in equation (1), polarization should be equal for all wavelengths and depend only on scattering angle θ. The original theory also deviates from the observation that the three neutral points in the sun's vertical have angular distances from the sun (or from the antisolar point) that vary with wavelength. These discrepancies increase in magnitude and in day-to-day variation with increasing atmospheric turbidity.

Lord Rayleigh himself questioned the assumption of primary scattering as being too limited. Light scattered once by an air molecule may be scattered by other molecules several times (multiple scattering) before it enters the observer's eye or the aperture of a measuring instrument. J. L. Soret later (1888) showed in a very crude quantitative way that partial polarization at 90° from the sun and the existence of neutral points were the result of multiple scattering.

Variations in colour and polarization after large volcanic eruptions suggest another reason for deviations from original Rayleigh theory. Estimates of the diameters of volcanic dust particles in the atmosphere, based on the position of Bishop's ring (a brownish ring around the sun observed after the Krakatau [*q.v.*] eruption of 1883), were comparable with or larger than the wavelengths of light. Direct measurements of haze or dust particles confirmed this estimate (*see* DUST), emphasizing that Rayleigh theory failed to include a general law of scattering for such large particles.

Multiple Scattering.—Inclusion of multiple scattering in the theory was considered even as late as 1942 as a "dream of the future" (C. Jensen). However, S. Chandrasekhar (1948) ingeniously solved the problem of radiative transfer in a plane-parallel atmosphere, taking account of primary scattering, multiple scattering, and polarization of scattered light. The mathematical complexity of the solution required high-speed computers; intensity and polarization of skylight for different wavelengths were computed and summarized in extensive tables.

Multiple scattering explained such deviations from the Rayleigh theory of primary scattering as partial polarization at 90° from the sun and its increasing degree of polarization with increasing wavelength. The modified theory also predicted three neutral points at angular distances (from the sun or the antisolar point) that vary with sun elevation and that decrease with increasing wavelength.

Quantitative empirical verification of the modified theory required that the previous visual measurements in broad spectral regions be replaced by accurate measurements in narrow spectral bands. A photoelectric polarimeter, constructed by Z. Sekera (1951), provided measurements that agree remarkably with theoretical values for the very short wavelength $\lambda = 3{,}650$ Å, and for very low atmospheric turbidity. Increasing turbidity and longer wavelengths yielded deviations (and daily variations) that increased noticeably. Discrepancies from theoretical values were noticed primarily in a decrease in degree of polarization and in a shift of the neutral points.

Large-Particle Scattering.—A more general theory of scattering, developed by G. Mie (1908), considers the measured size distribution of large haze or dust particles in the atmosphere, and is in very good agreement with measurements: the volume scattering coefficient varies with the wavelength at a much slower rate ($\sim \lambda^{-b}$, where $b \leqq 1.5$) or is independent of the wavelength. The intensity of light scattered by large particles shows a similar dependence on wavelength; when the atmospheric content of such particles is high, the normally dark-blue sky has a white, milky appearance. Large-particle scattering is highly unsymmetrical, showing up to a thousand times more forward than backward scattering. Thus scattering by haze or dust particles is predominant close to the position of the sun in the sky; there is always a white area of sky around the sun (the sun's aureole), the width of which can be used as a measure of atmospheric turbidity. Since light scattered by such particles tends to be only slightly polarized, increased atmospheric turbidity can be detected as a decrease in polarization of the clear sky. This decrease is proportional to the ratio of the volume scattering coefficient of the haze or dust particles to that of the air molecules; the ratio increases with wavelength. Hence deviations from modified Rayleigh theory increase from blue to red; since dust or haze content is variable, the deviations show similar daily fluctuations.

Twilight Colours.—The twilight sky (on the side of the rising or setting sun) at times shows a brilliant display of colour. Red prevails close to the horizon and gradually blends through orange, yellow, and purple into blue around the zenith. As the sun approaches the horizon, sunlight traverses relatively long paths through the atmosphere to reach the observer, and undergoes appropriately increased attenuation. If turbidity is low, blue wavelengths tend to be attenuated most, and their diminution or disappearance is sensed by the observer as the yellow, orange, or red of the sun or sky. In a hazy atmosphere attenuation tends to be the same for all wavelengths, and the observer senses decreased brightness of the sun, but little, if any, change in colour, even when the sun is at the horizon.

SKY DIVING: *see* PARACHUTE: *Sport Parachuting*.

SKYE, the largest island of the Inner Hebrides, Inverness county, Scot. From the mainland it is separated by the Sound of Sleat, Kyle Rhea, Loch Alsh and the Inner sound, and from the Outer Hebrides by the Minch and Little Minch. At Kyleakin, on the western end of Loch Alsh, the channel is only about ¼ mi. wide, and there is a ferry. The length of the island from southeast to northwest is 48½ mi., but its coast is deeply indented, so that no part of the interior is more than 5 mi. from the sea. It has a total area of 670.3 sq.mi. The population was 23,082 in 1841, 9,908 in 1931 (or 14.8 to the sq.mi.) and 7,478 in 1961. The chief arms of the sea are Lochs Snizort and Dunvegan in the north, Loch Bracadale in the west, Lochs Scavaig and Eishort in the south and Loch Sligachan in the east. The jagged mass of the Cuillin hills (Coolins) dominates the view. Their highest point is Sgurr Alasdair (3,309 ft.) and at least six other peaks exceed 3,000 ft.

To the north of Loch Slapin stands the group of Red hills of which the highest points are Ben Caillich and Beinn Dearg Mor and near Loch Ainort rises Ben Glamaig. About 8 mi. N. of Portree is the curious basaltic group of the Storr, consisting of pinnacles and towers, the most remarkable of which, the Old Man, forms a landmark for sailors.

Most of the land is moor and hill pasture but during the first half of the 20th century there was a considerable development in agriculture. The crofting system was still general at mid-20th century and while more crops were grown, the climate appeared to be better adapted for sheep and cattle. In 1953 there were approximately 104,284 sheep and 11,000 cattle on the island. The farms and small holdings were stocked principally with Blackface sheep although there were also Cheviot stocks. The condition of the crofters, which was pitiable in the extreme, was greatly improved by the Small Landholders (Scotland) acts 1886–1911, and in later years by the introduction of the government subsidies for cattle, potatoes and, until mid-20th century, sheep. The introduction of grants for various purposes enabled the black houses to be replaced principally by houses built of brick or concrete. With the opening in 1952 of the Storr Lochs hydroelectric power scheme, approximately 95% of the houses were supplied with electricity. The many ejections between 1840 and 1880 and the emigration that followed were mainly responsible for the serious decline of the population.

While the railheads at Kyle of Loch Alsh and Mallaig make the mainland markets accessible, road transport is extensively used. The fishing industry, which was at one time the mainstay of the population, declined during the first half of the 20th century. Whisky is distilled at Carbost. At Loch Cuithir, 4 mi. N. of Storr, work on the extensive diatomite deposits was restarted and in 1953 a factory, in which the raw material is processed, was opened at Uig. An afforestation scheme led to the reopening in 1953 of one of the 18 forestry schools closed as a result of the depopulation of the island.

The inhabited isles off the coast of Skye are mainly situated near the eastern shore. Of these the principal is Raasay, 13 mi. long by about 3½ mi. at its widest. Off its northwestern shore lies the isle of Fladda.

To the north of Raasay is Rona (seal island, from the Gaelic *ron*, a seal), 4½ mi. long with a maximum breadth of 1½ mi. The island is now unoccupied except for the lighthouse keepers whose families were removed to Portree in 1952. Scalpay, immediately south of Raasay, has a hill of 1,298 ft. The other isles are Pabay, Ornsay and Soay.

The islanders of Soay were evacuated in 1953 to Mull where they were established on new holdings by the department of agriculture for Scotland.

Portree (pop. [1961] 2,025), the capital, lies at the head of a fine harbour about the middle of the eastern seaboard. Steamers run daily to and from Mallaig and Kyle of Loch Alsh. There is a factory for tweeds, tartans and other woolens. During the cattle sales, held twice a year, large numbers of sheep and cattle are transported to the railhead at Kyle of Loch Alsh. The name Portree was derived from the fact that James V landed there during his tour of the western Highlands. The place thus became, in Gaelic, Port-an-Righ (the king's harbour).

It was to Portree that Flora Macdonald (1722–90) conducted Prince Charles Edward when he escaped from Benbecula. The sheriff's courthouse is situated in Portree.

Among other places in Skye associated with the Young Pretender are Prince Charles's point near Monkstadt, where he landed with Flora Macdonald, and Kingsburgh, on the eastern shore of Loch Snizort. The castle of the Macleods of Macleod, on a rocky promontory at Dunvegan, was erected in the 9th century and has the reputation of being the oldest continually inhabited house in Scotland.

The MacCrimmons, the famous race of hereditary pipers, hailed from this quarter of Skye and were attached to the Macleods of Dunvegan. At Duntulm is the ruined castle of the Macdonalds, another of the great clans of Skye chieftains. There is also much of archaeological interest in Skye. (J. Pp.)

SKYROS (Scyros; modern Greek Skiros), a rocky island of the Northern Sporades, Greece, in the Aegean Sea, 22 mi. (35 km.) NE of Euboea. Area 77 sq.mi. (199 sq.km.); pop. (1961) 2,882. The earlier inhabitants of Skyros were non-Greek Dolopes. There was a sanctuary of Achilles (*q.v.*) on the island; the legend was that he conquered Skyros, or that his mother Thetis disguised him as a woman in the palace of Lycomedes, to keep him from the Trojan War, but he was discovered by Odysseus, and accompanied him to Troy. Lycomedes was also said to have killed Theseus (*q.v.*) on Skyros. The island was seized *c.* 475 by Cimon (who recovered the "bones of Theseus") and settled by Athenians. It was under Macedonian rule in 196 B.C., when the Romans restored it to Athens. It was sacked by Goths, Heruli, and Peucini in A.D. 269. The ancient city was on a rocky peak, on the northeastern coast, where the modern capital Skiros stands (pop. [1961] 2,411). The English poet Rupert Brooke was buried on the island. (J. Bo.)

SKYSCRAPER. Until the middle of the 19th century, a commercial building more than four or five stories in height was rare, because tenants and their clients were reluctant to climb higher. However, desirable sites in business districts were expensive, and as business organizations multiplied, became larger and therefore demanded more space, the logical way to make economical use of those sites was to build upward. The key to the problem, a safe and efficient means of vertical transportation, was provided with the invention of the elevator safety device by Elisha Graves Otis in the 1850s (*see* Elevator).

The first safe passenger elevator was installed in the H. V. Haughwout store in New York city in 1857. Thereafter the development of the skyscraper as a unique architectural type was fairly rapid. The first taller-than-average structure (130 ft., compared with 60 ft.) to exploit the potentialities of the elevator was the Equitable Life Assurance Society building, New York city, erected between 1868 and 1870 by Arthur Gilman, Edward Kendall and George B. Post. In 1873 Post planned the headquarters for the Western Union company that rose 230 ft. and in the same year Richard M. Hunt designed the *New York Tribune* building to the height of 260 ft. Both buildings, in New York city, were completed in 1875.

Earlier Philadelphia architects had shown an interest in a solution that was more expressive of structure. In 1849 William L. Johnston introduced in the eight-story Jayne building a skeletal granite construction with columns that rose six stories without interruption, creating an illusion of unusual height.

In Chicago, during the last quarter of the 19th century, height and structural design were amalgamated in a distinctive manner. William Le Baron Jenney's Home Life Insurance Company building (1885) in particular marked a turning point in the construction of tall buildings: an internal metal frame (part cast iron, part wrought iron) supported the dead weight of floors and roof and the major load of the ten-story building, eliminating the necessity for massive foundations and thick bearing walls that had made structures of this height uneconomical. Jenney did not create skeleton construction without assistance from earlier architects and engineers.

Iron had been used in architecture for some time before the mid-19th century when European and U.S. architects and engineers exploited its structural advantages in a wide variety of buildings. In 1849 James Bogardus erected the Harper Brothers building, New York city, in which a rigid frame of iron columns and beams was the main support for the floor and roof loads; this represented a transition between the old masonry method and the system used by Jenney, in which the interior frame carried not only the roof and floor loads but the weight of the side walls as well.

During the 1870s in the American east and midwest, opposition developed to the rich external decorative treatment of the typical Victorian building. American architects began to employ surfaces relatively free of ornament, accenting the "skin and bones" of their buildings as could be seen in the Shillito Warehouse in Cincinnati (James McLaughlin, 1877). The Montauk block (1882) in Chicago, by Daniel Burnham and John W. Root,

often called Chicago's first skyscraper (130 ft.), was constructed of pressed brick and was nearly devoid of ornament. This approach to architectural design won many adherents in Chicago during the 1880s, giving rise to the term "commercial style." It appeared in the east concurrently but was used primarily for warehouses as distinguished from office buildings. By 1890 Chicago skyscrapers had developed a distinctive quality evolving from the first Leiter building (Jenney, 1879), the Borden block (1879–80) and the Troescher building (1884), the latter two by Louis Sullivan in partnership with Dankmar Adler. The 13-story Chamber of Commerce building (1889–90), by Edward Baumann and Harris Heuhl, with its division of the principal façade by columns into a series of bays with triple windows, its flat roof and its minimal use of ornament, was characteristic.

The buildings of Sullivan in particular expressed not only their business function and their structural character but their loftiness. One of his finest examples is the Wainwright building in St. Louis (1890), in which the skeleton frame of Jenney was combined with the kind of vertical articulation employed in Philadelphia. Sullivan divided the edifice into three main parts, a base, an upper section and an attic story, capped by a flat, projecting cornice. The window treatment expresses the fact that the main section is composed of identical offices. For vertical emphasis he accented columns, a number of which are not structural, that rise without interruption from base to cornice. This formula was repeated in his Prudential building (Buffalo, 1895) and Bayard building (New York, 1899).

Architects along the eastern seaboard were more derivative, basing their work on older styles of architecture. In the 1880s a Romanesque manner, popularized by H. H. Richardson, enjoyed a vogue that spread westward throughout the country. The 14-story Ames building (1889–91) by George F. Shepley, Charles A. Rutan and Charles A. Coolidge, one of Boston's first skyscrapers, is typical.

The next decade saw a shift to the Neoclassical style, made fashionable by the architects Charles Follen McKim, William Rutherford Mead and Stanford White, founders of the firm of McKim, Mead and White. Skyscrapers were modeled after the Greek column with its tripartite division of base, shaft and capital. The Graham building (1898) in New York city, by Charles W. Clinton and William H. Russell, which was typical, had a base of lower floors containing a lobby and banking space, a shaft composed of identical offices and a capital of several attic floors topped by a projecting cornice.

Some architects, such as Bruce Price, conceived of the skyscraper as a tall, free-standing, vertical shaft. The American Surety building (1895) in New York exemplifies this concept. Others found a precedent in the medieval bell towers of Europe as in the case of the Metropolitan Life Insurance building (1909), New York, modeled by Napoleon Le Brun after the campanile in Venice, and the Woolworth tower (1913), New York city, by Cass Gilbert, in the Gothic style.

Many speculators took advantage of the absence of building codes to raise gigantic structures without concern for aesthetic expression or for the many civic problems such buildings created. The result was the adoption in many cities of zoning laws to prevent the formation of dark, canyonlike streets, and thus the setback skyscraper became commonplace in U.S. cities. One of the finest of this type was the *Daily News* building, New York city (Raymond M. Hood and John M. Howells, 1930). It was at this time that the International Style with its emphasis on the horizontal rather than vertical began to make its influence felt on skyscraper design. Hood and Howells' striped and glassy McGraw Hill building (1931), New York city, and George Howe and William Lescaze's Philadelphia Saving Fund Society building (1932), Philadelphia, reflect the thinking of Walter Gropius, Ludwig Mies Van der Rohe and other European architects during the early 1920s.

During the 1920s New York skyscrapers reached their greatest heights: the Chrysler building (William van Alen, 1929), 77 stories (1,046 ft.), and the Empire State building (Shreve, Lamb and Harmon, 1930), 102 stories (1,250 ft.). Thereafter architects tended to think in terms of 30- or 40-story structures, recommending buildings of smaller size but better design as safer enterprises economically.

One of the first projects illustrating this changed attitude was Rockefeller Centre in New York by Reinhard & Hofmeister; Hood and Fouilhoux; Corbett, Harrison and MacMurray (1929–40). On its three-block site, the associated architects could have raised the highest structure anywhere; instead they chose to build a major skyscraper of 66 stories surrounded by structures of about half that height. Consideration was given to light, air and open space as well as to fine-quality materials, landscaping and ornamental works of art. The financial success of this project and the prestige it acquired led to similar planning in the United States and elsewhere.

The most notable examples of the World War II period were the glass-sheathed Equitable Life Insurance building in Portland, Ore. (Pietro Belluschi, 1948), Lever House (Skidmore, Owings and Merrill, 1952), and the *Time* and *Life* building (Wallace K. Harrison and Max Abramovitz, 1959), both in New York city. All of these reflect the influence of Mies Van der Rohe, who along with Philip Johnson designed the Seagram building, New York city (1957). The aluminum-clad Alcoa building in Pittsburgh by Harrison and Abramovitz (1952) shows the trend toward metal curtain wall construction. Less influential but nevertheless significant is Frank Lloyd Wright's Price tower at Bartlesville, Okla. (1955–56). Noteworthy too are the sunscreen-covered structures of South America deriving from the work of Le Corbusier. Typical is the Caramuro building by Paulo Autunes Ribeiro at Salvador, Bahia (1946). Le Corbusier was also instrumental in promoting the use of wedge and claw-shaped forms into skyscraper design as a means of achieving maximum amounts of well-lighted working space.

SLANDER: *see* DEFAMATION.

SLANE (SLÁINE), a picturesque little village situated in the Boyne Valley 8 mi. (13 km.) NE of Navan in County Meath, Republic of Ireland. Pop. (1961) 421. It was the birthplace (1891) of the poet Francis Ledwidge, who was killed in World War I. Mervyn Archdall (1723–91), the author of *Monasticum Hibernicum* and rector of Slane, is buried in the Protestant churchyard in the village. The old village square is now surrounded by shops and houses, many of them Georgian, and forms the hub of social and commercial life. Slane Castle, seat of the marquis of Conyngham, stands by the river approximately 1 mi. W of Slane, and beyond it are the ruins of Castle Dexter. Rosnaree, the legendary burial place of the 3rd-century King Cormac Mac Art, lies 2 mi. (3 km.) S.

Just north of the village is the Hill of Slane where traditionally St. Patrick challenged the Druids' power by lighting the Paschal fire himself in place of the king. He later built a monastery there but no trace of it remains. (W. M. PO.)

SLANEY, a river of the Republic of Ireland, 73 mi. (117 km.) long, rises in Lugnaquilla (3,039 ft. [926 m.]), County Wicklow, the highest mountain of southeast Ireland. The Slaney turns westward in a steep torrent course to the Glen of Imail, a basin cut in granite at 500–700 ft., and then assumes a north-south line and wanders through the farmed lowlands of County Carlow and through Tullow to Bunclody just inside County Wexford. There it is joined by the Clody and continues southeast through the Slaney Gap, the only lowland route through the mountain chain that dominates the southeast of Ireland. In its journey from the gap across the fertile lowland of Wexford, the river is between 50 and 100 ft. below the general surface which stands at about 200 ft. above sea level. It receives two major tributaries, the Derry just above Bunclody, and the Bann north of Enniscorthy, both of which flow from the northeast in wide, well-farmed corridors of lowland. At Enniscorthy (*q.v.*) the river becomes tidal, and quays were built in the 19th century for barge traffic to Wexford (*q.v.*). The Slaney finally enters Wexford Harbour, a sheltered inlet of much more importance for shipping in the 19th century than at present. (T. W. FR.)

SLANG, an informal and colloquial variation of or addition to standard speech. It may be a variation in any element of a language—in its sounds ("atta dirl"), in its stress (posi*tiv*ely"), in its intonation ("Is that so?"), in its syntax ("We was robbed"); but it is in vocabulary ("spiv") and meaning ("She's a peach") that slang is commonest.

Slang is formed by normal linguistic processes found in all living languages, processes such as compounding ("low-down," "sob stuff"), word clipping ("pro," "mike," "pix"), abbreviation ("OK," "VIP," "snafu," "q.t."), onomatopoeia ("boom," "whiz," "bang"), generalization of proper names ("bobby," "guy," "real McCoy"), borrowing from dialects and foreign languages ("vamoose," "savvy," "pronto," "loco"), and extension of meaning by analogy ("Park your hat," "He got pickled").

ORIGINS AND USES OF SLANG

Slang and Society.—People belonging to the same social group —of the same trade, profession, hobby, age, or social position— tend to behave in the same way. This behaviour influences not only the clothes they wear but also the language they use. The language of a social group, particularly its slang, is one of several forms of behaviour that keep the group distinct from other groups. As a verse writer has aptly put it, "The chief use of slang/Is to show that you're one of the gang" (R.D.C. in the *New Statesman and Nation*, London, Nov. 16, 1946).

One of the commonest social groupings is that of people who work together. Students have their "lab" and their "gym." Secondhand car dealers have their "cream puffs" (excellent cars) and their "dogs" (dilapidated ones). For an order of poached eggs on toast a waitress may tell the cook to "drop two on." To a television producer a poor show may be a "wart." A circus "geek" (conditioned freak) can use a "stick" (decoy) to attract a "tip" (prospective customer); but this is not the same sort of tip that a hotel porter might expect from a "front" (inexperienced traveler). A professional flyer may wear a "brain bucket" (crash helmet) in case he has to "buy a farm" (crash); but his "soup" (horsepower) has nothing to do with the "soup" (nitroglycerin) of the professional safecracker. "Cat" does not refer to the same thing in the underworld as it does in the jazz world. Yet both underworld and jazz slang form the basis of much "teen talk."

Some social conditions are more favourable than others to the creation of slang. Excitement, crowding, and the sudden regrouping of people for a particular purpose, as in wartime, may result in the formation of a large number of slang words. This goes on from person to person, from ally to ally and from one side to the other. All the participants learn things about the others, and all come out with larger vocabularies. Forceful expressions by the thousand are created and used by members of the armed forces. "Big Bertha" is remembered as the nickname of the long-range German cannon in World War I, immortalizing Bertha Krupp of the munitions family. The innocent-sounding "pineapple" of the same war was a hand grenade with markings suggestive of the fruit. World War II added another type of grenade, the "Molotov cocktail," and a vast new vocabulary of slang including such words as "blitz," "doodlebug" and "walkie-talkie." The Korean War also had its slang; Korean soldiers were known as "gooks" and as "ROKs." A few slang expressions, such as "OK," the international sign of approval or assent (*see* O.K.), have spread far beyond their original linguistic boundaries.

How Slang Develops.—A witticism of a single person may be enough to launch a new slang form. The novelty may produce a response so effective that it is taken up by others and soon becomes widespread. The more it is used, the more popular it becomes, especially if it is used by associates or admired persons. But after much use the novelty wears off, and the expression, having no special effect and therefore no further function, dies out. If, however, the older form or its central meaning has in the meantime gone out of fashion, the slang expression may remain in use as the normal form. This was the case when the Latin word *testa* ("earthen pot"), used jocularly to describe the head of a baldheaded man, supplanted the normal word *caput* and later became the usual form for head in Italian (*testa*) and in French (*tête*). Similarly, *gamba* ("hoof"), the Latin slang word for leg, became the standard word for leg in both French (*jambe*) and Italian (*gamba*), the latter being the word from which "gam" in modern American slang was most probably derived.

When literary men in the 17th century wrote about the "common people" they often used a Latin expression, *mobile vulgus*, meaning the fickle or movable crowd. Sometimes in writing this was abbreviated to *mob. vulg*. Later the *vulg*. was dropped, and careless writers began to use *mob*. alone, still pronouncing it in full, *mobile*. The next step was to say simply *mob*, which was considered shockingly low and regarded as the crudest type of slang. The usage persisted, and in the 18th century "mob" became tolerated in conversation, although not in writing. Early in the 19th century came another promotion, and the word, at long last, entered the ranks of standard English. A similar process was responsible for about 2% of conventional English words; such words as "trip," "bet," "donkey," "shabby," "chap," "bore," "cab" and "kidnap" were once condemned as slang.

Some words may remain as slang for centuries, neither disappearing nor becoming part of the standard vocabulary. Such is the case of the medieval "booze," the Elizabethan "rook" (verb), and the 18th-century "swop." The same applies to certain expressions such as "dead as a doornail," which was used in the 14th century and may have been old even then. In the 16th century Shakespeare, in *Twelfth Night*, wrote "laugh yourselves into stitches." In the 17th century George Fox, founder of the Quakers, wrote about a professional man who had "done his stuff," proving early currency for another expression still in use.

Yet for every slang expression that has lived, hundreds of others have died. "Gamp" was once the usual slang name for an umbrella. It was named after a large, bulging umbrella carried by Sairey Gamp, in Charles Dickens' *Martin Chuzzlewit*, published in 1844. In the latter part of the 19th century it became a well-established colloquialism, but it was hardly important enough to last.

It is in the area of fundamental emotions that slang is most changeable and most productive. The slang of approval ("swell," "nifty," "bong," "dilly," "the end," "smashing") and disapproval ("phooey," "nuts," "baloney," "hogwash," "flapdoodle," "poppycock") may change within a generation. So may the words for woman and girl ("skirt," "biscuit," "swan"), and these are usually numerous in any generation. When a young man refers to his sweetheart as his "soul mate," his "steady," his "main dish," his "heavy" or his "onliest" he has hardly made a beginning; he could use a different expression every day for three years and still have words left over for variety. It is the same with money, which has unconventional synonyms by the bookful, including such picturesque terms as "berries," "cabbage," "chink," "ducats," "jack," "mazuma," "moola," "potatoes," "simoleons," "spondulics" and "wampum." The expression "to die" seems much too commonplace; a person is said to "drop off," "fade out," "go to grass," "go under," "go up," "go west," "kick the bucket," "pop off the hooks," "shuffle off" or "push the clouds," with probably a thousand variations. A person suffering from the effects of drinking to excess is said to be "afloat," "blowed," "boozy," "cockeyed," "corned," "disguised," "fractured," "groggy," "high as a kite," "ratty," "stewed," "vulcanized" or "smashed." The idea of stealing is expressed in slang in many forms, some of them with a disarming suggestion of innocence, such as "promote," "salvage," "rustle" and even "liberate." Other synonyms, ranging all the way from "annex" and "appropriate" to "souvenir" and "freeze onto," would easily exceed a thousand. The same may be said of all fundamental words, the words first used by children and by "primitive" people. They seem to seek synonyms—humorous, satirical, poetical, euphemistic or merely roughly descriptive— in slang.

Catchphrases.—Catchphrases, more or less related to slang, are of many kinds, ranging from the whimsical and witty to the meaningless and inane. Popular catchphrases in the 19th century included "Who stole the donkey's bed?" addressed to men wearing straw hats; "What a tail our cat has," a bantering reference to a woman's new dress; "Does your mother know you're out?" a

supposedly funny remark of wide application. Many 19th-century examples were based on music-hall songs, as "Where did you get that hat?"; "Shoo, fly, don't bother me"; and "A hot time in the old town tonight." A similar inane specimen in the 20th century was "Yes, we have no bananas." Catchphrases still come and go, and still bear study, for they tend to reveal the processes, mental or emotional, of the people who utter them.

Artificial Types.—Since one of the functions of slang is to prevent members of other groups from understanding what is said, it is not surprising that attempts have been made to create systems of slang to function as secret languages. These include such artificial types as rhyming slang, back slang and centre slang. Rhyming slang was used by certain Cockney groups as early as 1840; it spread to the Australian underworld and after World War II became popular among the young "teddy boy" gangs in London and other English cities. In rhyming slang a wife becomes "trouble and strife," a road a "frog and toad" and a suit a "whistle and flute." This becomes even more secret when the rhyming word is omitted, whereby a road becomes a "frog," a suit a "whistle," a hat a "tit for" (tat) and mouth a "north" (and south). Back slang consists in saying a word backward with any alteration necessary to make it more pronounceable. In this way a game becomes an "emag," a market a "tekram," drunk "kennurd" and police "slop." In centre slang, the first syllable of the slang word is formed from the first vowel of the standard word and the consonant that follows it; the other syllables may be made in a number of ways, either with fixed or free suffixes. To call a man a fool in centre slang, such terms as "oolfoo," "oolerfer" and even "hoolerfer" could be used.

National Slang.—It is not surprising that world English shows traces of American influence. This influence, which tends to create variety but not disunity, extends into the field of slang. The americanizing process has been aided by media of mass communications, but it should be pointed out that communication is a two-way street and that Americans have not been slow to import "Briticisms." (*See* also AMERICAN ENGLISH.)

On the continent of Europe, slang was being recognized as early as the 12th century and studied at least as early as the 15th, when François Villon used it and probably added to it in some of his immortal ballades. A generation later, in Germany, Martin Luther wrote a preface to the 1529 edition of *Liber Vagatorum* (*Book of Vagabonds*) and gave his views on the vocabulary of vagabonds' slang featured in that work. Villon and Luther had one thing in common—they were both writers, and writers recognized, then as now the strong human appeal of certain types of slang.

Attitudes Toward Slang.—Some writers have condemned all slang especially that of hostile classes. They have called it vulgar, corrupted, uncultured, secret and false, the dialect of the rabble, of beggars, of gypsies, and of thieves. Others have praised slang as creative activity. The critic G. K. Chesterton said that "all slang is metaphor." The semanticist S. I. Hayakawa called slang "the poetry of everyday life." According to most students of language, slang in itself is neither good nor bad. It is part of the natural growth of language. A living language must continually change, and some of the changes first appear as slang. Some slang makes the language capable of new and delicate shades of meaning or adds vividness, clarity and directness to everyday expressions. Other slang expressions are vague in meaning, cover too much ground or duplicate better conventional vocabulary. Judgment on the propriety or effectiveness of an expression—and even whether it is or is not "slang"—requires knowledge of the context in which it appears.

When Elisha Coles issued his *English Dictionary* in 1676, he explained the inclusion of a number of slang words and expressions by saying, "'Tis no Disparagement to understand the Canting Terms: It may chance to save your Throat from being cut, or, (at least) your Pocket from being pick'd." Reasons less ominous impel the modern student, who knows that from slang much can be learned about the history, customs, fashions, the very thoughts of people far away or long ago. The study of unconventional speech is of immense value to authors and playwrights.

(A. McQ.; W. F. MY.)

SLANG TERMS

The following lists of slang terms are representative of mid-20th-century usage in the principal English-speaking countries. While all the terms are in current use, not all are of modern invention and not all are necessarily used exclusively in the country to which they are attributed. Much American slang has gained currency in the United Kingdom, and much, especially older, British slang has become established in the United States. As for Canada, where there is comparatively little native slang, most current slang derives from the adjacent United States; there is little general U.S. slang that is not used also among Canadians. British slang, on the other hand, is far less extensively used among native Canadians, although many older terms are well established. Australia has developed a vigorous native slang, much of which is shared by New Zealand; but here, too, much British slang has long been current and, particularly during and since World War II, American slang has made substantial inroads.

UNITED STATES

action *n.* profitable activity in gambling or crime
ants *n.pl.* anxiety; restlessness (antsy *adj.*)
applesauce *n.* (1) nonsense (2) flattery
bail out *v.* help out of a difficult situation

crook *adj.* ill; worthless; go crook: become angry
cut out *v.* complete a task
damper *n.* bush bread baked in ashes or a camp oven
dead ring of: exactly similar to
deaner *n.* shilling
Digger *n.* Australian soldier
dillybag *n.* native bag made of grasses or fur twisted into cord
dingo on (someone) *v.* betray
dinkum *adj.* true; honest; also, dinky die, fair (square) dinkum
do a perish: almost to die for want of a drink
do one's block: become angry or excited
dreaming *n.* any source of native legend
drink with the flies: to drink alone
drop one's bundle: become panicky
drunk as Chloe: extremely drunk

duffer *n.* cattle thief; whence, duffing
fizgig *n.* police informer
fossick *v.* search for surface gold; look for something; whence, fossicker
full as a goog: completely full; extremely drunk
furphy *n.* baseless rumour or canard
game as Ned Kelly: highly reckless or courageous
gin *n.* adult native woman
give it a burl: make an attempt at
go bung: peter out; die
go on the wallaby: wander in the outback
go walkabout: travel; wander
graft *n.* hard work
guyver *n.* tall talk; affectation
happy as Larry: completely happy
hard case *n.* reckless or amusing person
hatter *n.* man who lives and works alone
haven't a skerrick: to be penniless
haven't the bolter's: to have no chance at all of success
hooray! *interj:* good-bye
humpy *n.* hut; small shack
in smoke: in hiding
jackeroo *n.* young station hand, learning sheep or cattle farming
jacko *n.* (1) kookaburra; (2) jack, jackass
Jimmy Woodser *n.* solitary drinker
joey *n.* (1) young kangaroo (2) baby (3) lie
jumbuck *n.* sheep
keep nit *v.* mount guard while some illegal activity is afoot; also, to cockatoo
kidstakes *n.* pretence; foolery; nonsense
lair *n.* flashily dressed youth; lairy: flashily or showily dressed
larrikin *n.* street tough or hoodlum
lolly *n.* sweetmeat
lubra *n.* young native woman
lurk *n.* (1) scheme; racket (2) dart
Maoriland *n.* New Zealand; also, Enzed, Pig Islands, Shakey Isles
Merino (pure) *n.* first class in quality
no good to gundy: worthless
nohoper *n.* person who has no prospects of success
nuggety *adj.* short; thickset; sturdy
offsider *n.* helper or companion
Old Dart *n.* England
old identity *n.* old, noted inhabitant of a locality
outback *n.* inland country; bush
paddock *n.* any fenced area of land
pastoralist *n.* any farmer engaged in the primary industries
perform *v.* curse luridly; give way to temper
plonk *n.* cheap wine
poddy *n.* hand-fed calf, lamb, foal
point *v.* take unfair advantage of another; loaf; malinger
poke borak at: jeer at; make fun of
pommy *n.* English-born person
poofter *n.* male homosexual
possie *n.* place or position
push *n.* gang or clique
put the hard word on: lodge an urgent demand
Rafferty rules *n.pl.* no rules at all
ratbag *n.* eccentric person
ready up *v.* conspire; fake; *n.* conspiracy; "stew"
removalist *n.* person or firm engaged in shifting household effects
ridge *adj.* excellent; genuine
ringer *n.* fastest shearer in a woolshed; any expert
ropable *adj.* angry; savagely ill-tempered
rough as bags: unpolished; crude
rouseabout *n.* handy man on a sheep or cattle station
rouse on *v.* upbraid; reprove
run *n.* large farm for sheep or cattle; station
sandy blight *n.* form of ophthalmia
scale *v.* ride on a tram, train, or bus without paying
shanghai *n.* catapult
sheila *n.* girl
shicer *n.* shyster; swindler
shicker *n.* intoxicating liquor; shickered: drunk
shivoo *n.* spree; party
shoot through *v.* quit; decamp
shout *v.* stand treat
silvertail *n.* social figure; social climber
sly grog *n.* liquor sold illegally; place where it is sold
smoodge *v.* make love to; curry favour
snags *n.pl.* sausages; snorks, snorkers
sool on *v.* incite
southerly buster *n.* wild wind or gale from the south
squatter *n.* owner of a large sheep or cattle station
squib *n.* coward
stickybeak *n.* inquisitive person
stoush *v.* hit; thrash; *n.* violence
sundowner *n.* tramp of indolent habits
swag *n. see* bluey; swagger, swaggie, swagman: a tramp
Tassie *n.* Tasmania; Tasmanian
tinny *adj.* extremely lucky
tipslinger *n.* race tipster
top end *n.* far north Australia; topender: resident of the far north
tote *n.* totalizator or pari-mutuel
trot (a good) *n.* sequence of successes; bad trot: sequence of failures
tucker *n.* food
turf out *v.* reject; throw away
two-up *n.* gambling game played with two pennies
up a gum tree: in a quandary
up to putty *adj.* worthless
urger *n.* race tipster; trickster's confederate
waddy *n.* stick or club
wake-up *n.* alert person
waltz matilda *v.* go on the tramp
weekender *n.* weekend holiday residence
whacko!: ejaculation of pleasure or approval
whinge *v.* complain; grouse; whence, whinger, whinging
whip the cat: cry over spilled milk
white ant *v.* undermine or sabotage
willy-willy *n.* wild storm of tornadic type
wog *n.* germ; parasite; small insect; foreign-speaking immigrant
Woop Woop *n.* (hypothetically) most rustic of all rustic townships
wowser *n.* puritanical fanatic; bluestocking
yabber *v.* talk; chatter
yacker *n.* work
zack *n.* sixpence
ziff *n.* beard

New Zealand

All Blacks *n.* New Zealand representative footballers
batch *n.* small shack or cottage; batcher: one who lives alone
bot *n.* cadger or parasite
box of birds: happy; in full health
Enzed *n.* New Zealand; Enzedder: New Zealander
fire in the fern *n.* trouble; smouldering discontent
half-pie *adj.* worthless
have the wood on: have an advantage over
hoot *n.* money
kai *n.* food
kit *n.* shopping basket
over the fence: unreasonable
pakeha *n.* white man
pie at *adj.* expert at; efficient
wahine *n.* woman
whare *n.* small shack or cottage

(S. J. Br.)

Bibliography.—For practical purposes, books regarding slang can be divided into two classes, early (virtually unobtainable) and modern (1900 to date). The latter include a few popular works, such as *A Dictionary of Slang and Unconventional English*, rev. ed. (1961), by E. Partridge, or *Dictionary of American Slang* (1960), by H. Wentworth and S. B. Flexner. In *American Thesaurus of Slang* by L. V. Berrey and M. Van den Bark, 2nd ed. (1953), the words and expressions, though not individually defined, are minutely classified and indexed. H. L. Mencken's *The American Language*, 4th ed. (1936), and its two supplements (1945, 1948) contain much lively material on slang. *A Dictionary of Americanisms on Historical Principles* (1951), ed. by M. M. Mathews, includes many slang expressions, with dated quotations. Current studies, many of them of interest in British circles, appear in the periodical *American Speech* (1925–). Australasian slang is discussed in S. J. Baker's *Australia Speaks* (1953) and *New Zealand Slang* (1941). War slang is represented in *A Dictionary of Forces' Slang, 1939–1945* (1948) by E. Partridge, W. Granville, and F. Roberts. A good sampling of sailors' slang can be found in W. Granville, *A Dictionary of Sailors' Slang* (1962). Underworld slang is represented in H. E. Goldin (ed.), *Dictionary of American Underworld Lingo* (1950), and E. Partridge, *Dictionary of the Underworld, British and American* (1950). French slang is described, classified, and indexed in A. Dauzat's authoritative *Les Argots* (1929). German slang is likewise discussed and listed in *Wörterbuch der Kunden- und Gaunersprache* (1939) by A. Bertsch. *The Literature of Slang* by W. J. Burke (1939) is a useful bibliography.

(A. McQ.; W. F. My.)

SLATE, in geology, fine-grained argillaceous or clayey metamorphic rock which cleaves or splits readily into thin slabs having great tensile strength and durability. Some other rocks that occur in thin beds are improperly called slate because they can be used for roofing and similar purposes. True slates do not, as a rule split along the bedding, but along planes of cleavage, which may intersect the bedding at any angle, usually, in the case of good roofing slates, at high angles. The original material was a fine clay, sometimes with sand or volcanic dust, and the bedding of the sediment as originally laid down may be indicated by alternating bands, differing in colour or in lithological character, sometimes to be seen on the cleavage faces of the slates. Cleavage is a superinduced structure, the result of pressure acting on the rock at some time when it was deeply buried beneath the earth's surface. On this account slates are found chiefly among the rocks of the older geological systems, although some occur in regions where comparatively recent rocks have been folded and compressed as a result of mountain-building movements in the earth's crust.

In thin sections for microscopic examination, slates show much colourless mica in small, irregular scales, which in the best average about 2,000 to the inch in breadth and 6,000 to the inch in thickness. Green chlorite in flakes is also usually abundant, the principal other ingredient being quartz, in minute lens-shaped grains. In colour, slates may be black, blue, purple, red, green or gray; dark slates usually owe their colour to carbonaceous material or to finely divided sulfide of iron, reddish and purple varieties to the presence of oxide of iron in the form of hematite and green varieties to the presence of much chlorite.

Slates are made or split from quarried blocks about three inches thick. A chisel, placed in position against the edge of the block, is lightly tapped with a mallet; a crack appears in the direction of cleavage, and slight leverage with the chisel serves to split the block into two pieces with smooth and even surfaces. This is repeated until the original block is converted into 16 or 18 separate "slates," the thickness of which depends upon many circumstances, such as quality of rock, size required and purpose for

which it is to be used, the average thickness of a roofing tile of the best kinds of slate being about ⅙ in. The slates are afterward trimmed to size, either by hand, in which case they are cut between a fixed sharp edge and a movable knife acting on the principle of a paper cutter, or by means of machine-driven rotating knives.

Slate also is sold as dimension slate and crushed slate (granules and flour). Dimension slate is used mainly for electrical panels, laboratory table tops, roofing and flooring and blackboards. Crushed slate is used on composition roofing, in aggregates and as a filler. Principal production in the United States is from Pennsylvania and Vermont; lesser quantities are quarried in Maine, New York, Virginia, Georgia, Arkansas and California. North Wales provides most of the slate used in the British Isles. *See* also STONE. (F. J. N.; F. J. P.)

SLAUGHTERHOUSE (ABATTOIR), a place where food animals are butchered.

Methods of Slaughter.—In early times domestic meat animals were slaughtered by strangulation or by piercing the brain through the eye sockets with heated spears. The blood was cured in as an essential part of the meat. The Judaeo-Christian distaste for blood led to development of new practices: animals were dispatched by a head blow or by quick severance of the jugular vein, and the carcass was hung head downward to bleed (*see* also KOSHER). After bleeding, cattle and sheep were skinned, while pigs were dipped into vats of scalding water so that hair or hide or both could be easily removed.

In the modern abattoir, animals are usually stunned before being bled, a practice that indicates interest in the humane treatment of animals produced for slaughter. In both the United States and Europe the desirability of stunning was recognized before the end of the 19th century, and mechanical equipment for this was developed. Cattle may be stunned by means of a captive-bolt pistol or a pneumatic gun. Sheep and pigs may be stunned by pistol, by electric shock, or by anesthetizing in a carbon dioxide chamber. After World War II compressed-air stunners were commonly used for cattle and gas chambers for smaller animals. From 1960 U.S. federal legislation required federal agencies to buy meat produced only from animals slaughtered by humane methods.

In addition to stunning devices, large modern abattoirs use a wide variety of mechanical, electrical, and pneumatic equipment for the various slaughtering and carcass dressing and processing operations. The moving chain-conveyor production line system is widely used where the scale of operations warrants it.

History.—*United States.*—Early slaughterhouses were operated on a small scale, but the increasing demand for meat and the concentration of populations in the expanding urban areas led to the establishment of large abattoirs.

The first known meat packer in America was William Pynchon, treasurer of Massachusetts Bay Colony and founder of Springfield, Mass., who during the 1640s built an abattoir on the bank of the Connecticut River, 7 mi. (11 km.) S of Springfield. There he processed salt pork and beef for shipment to West Indies plantations. Pynchon's son John reduced the seasonal nature of meat production by wintertime stall-feeding of cattle, and in 1655 he trailed a herd of fat spring beeves to Boston. Since the cowboy was, and is, a commercial cattle drover, John Pynchon is regarded as the "father" of the American cowboy.

Commercial abattoirs developed along the Atlantic Seaboard, in the Southwest, and in California during the 17th and early 18th centuries. The cowpens of the Carolina and Georgia mountains supplied meat and leather for the coastal cities and the West Indies. Spanish and Indian *vaqueros* and *ciboleros* doubled as cowboys and butchers in the Far West. They and their West Indian counterparts, the boucan makers (*i.e.*, buccaneers), developed "jerky," the modern dried beef and originated the skills of the roundup and the first crude rodeo (*q.v.*).

Meat packers followed the livestock west after the Revolution. After 1830 Cincinnati, because of its location on the Ohio River waterway, became the largest western meat-packing centre, hogs and cattle being driven there for processing during the fall months. Rapid methods of dispatch and cure were necessary so that the salt and smoked meats might be shipped west and south before the waterways froze. Each workman performed a single cut or act as the carcasses, suspended head down from endless belts, were pulled slowly across the processing room. In Cincinnati the first major experiments were conducted in year-round refrigeration of meats.

The impoverishment of Texas after the Civil War, coinciding with the U.S. Army's campaigns against western Indians, sent millions of wild Longhorn cattle trailing north and northwest to the prairies and high plains (*see* LONGHORN). This, and the coincidental development of transcontinental railroads, enabled Chicago to become the nation's greatest meat-packing centre. Until the late 1860s live animals were shipped to eastern cities and to Europe. Then refrigerator cars were introduced (*see* REFRIGERATION: *Applications of Refrigeration*), and by 1870 Chicago packers processed, dressed, and cured more than 10,000,000 meat animals each year. Succeeding decades saw the development of huge abattoirs and processing plants in Chicago, Omaha, Kansas City, Denver, and other railway centres of the prairie and West.

The Cincinnati gravity system was generally followed. Cattle were driven via inclined ramps to the top floor of the plant, where they were stunned by mallet blows and hung from moving belts to travel slowly downward through the jugular-cut, bleeding, and dissembly stages of processing. Pigs and sheep were shackled, suspended, and then "stuck." The entire operation from shackling pen to carcass required less than one minute.

After 1920 the bulk of livestock transit shifted from railroad to highway truck, reducing the dependence of abattoirs on rail centres. Radio and, later, television enabled growers and feeders to keep abreast of market quotations and needs. Hundreds of auction markets thus developed, in small towns and at crossroads, where livestock was sold to middlemen or directly to packers through the British system of open bidding. By 1950 these changes had led to a decentralization of slaughtering and a decreased use of some of the large abattoirs, including the vast Chicago Union Stock Yard.

Europe.—Slaughterhouses in Europe during the 19th century were governed by purely local considerations and were small, serving consuming areas. The local town council often provided a public abattoir, thus maintaining control of the interests of public health, at which any farmer or butcher could slaughter his own animals on payment of a fee. Consequently European abattoirs did not adopt mechanical equipment as early as the large meat-packing centres in the U.S. did. Nevertheless, in the 1960s, in some European countries large and well-equipped abattoirs were in use.

Meat Inspection.—Local and central government authorities in many countries have long recognized that without adequate supervision and control during slaughter, meat can be a serious source of infection. In the United States, charges of insanitary conditions in slaughterhouses, originating in British medical journals and publicized by Upton Sinclair's novel *The Jungle*, led, after 1906, to federal legislation providing for the sanitary supervision of slaughterhouses and meat-packing plants, and of their products, by federal inspectors. Chicago's sprawling and odorous Union Stock Yard, founded in 1865, was the most famous of the livestock terminals brought under federal inspection by this legislation.

Public health authorities in nearly all countries in the 1960s operated a system of rigid inspection and control. Animal health was checked on the farms and at the abattoirs, prior to slaughter, and the carcasses were checked during and after slaughter. The risk of diseases being transmitted by meat has thus been reduced to infinitesimal proportions. (*See* further MEAT: *Inspection.*)

Refrigeration maintains the meat in good condition after slaughter. By dispelling the body heat from the carcass as quickly as possible, the risk of bacterial growth is significantly reduced. The development of mechanical refrigeration in the second half of the 19th century enabled the sheep-producing countries, notably Australia and New Zealand, to develop a substantial export trade in frozen lambs, and large abattoirs have been established in those countries to serve that trade.

Slaughterhouse By-Products.—Apart from the principal products of meat, the slaughter of animals produces many by-products, the most important of which are hides, for the manufacture of leather (*q.v.*), and fats that may be rendered into lard and used in the manufacture of soap.

When synthetic detergents and vegetable shortenings reduced the markets for these animal fats, large firms built plants where fat surpluses could be converted into fatty acids and complex chemicals for use in a great variety of products. Intestines are cleaned and processed for use as sausage skins, and glands are used in the pharmaceutical industry and for therapeutic purposes. Blood, which is rich in proteins (but which is drained from the animal to improve the keeping quality of the meat), is used in manufactured meat products, such as the English black pudding; in the manufacture of adhesives, animal feeding meals, and fertilizers; in the clarification of wines; and for other industrial purposes.

See also MEAT: *The Meat Industry;* FOOD SUPPLY OF THE WORLD; and individual articles such as BEEF; PORK; LAMB AND MUTTON; SAUSAGE AND READY-PREPARED MEATS, etc., for production, distribution, and preparation of meats. Further information on meat processing will be found under FOOD PREPARATION; FOOD PRESERVATION; and CANNING, COMMERCIAL.

SLAVE COAST, a term denoting the low-lying deltas and sandbars of the West African coast that stretch for about 700 mi. (1,130 km.) between the Volta River and Mt. Cameroon used (but now rarely) to distinguish this shore line from the Gold, Ivory, and Grain coasts. The name derives from its former position as a principal source of African slaves for 350 years, especially the section of it that fronts on the Bight of Benin. (D. WH.)

SLAVEIKOV, PETKO RACHEV (1827–1895) and **PENCHO** (1866–1912), Bulgarian writers, father and son, who helped to enrich Bulgarian literature by establishing a modern literary language and introducing contemporary ideas from other European countries.

Petko Rachev Slaveikov, born in Trnovo on Nov. 17, 1827, became an itinerant schoolteacher at 17. His early poems were lyrical and patriotic (*Smesena Kitka, Pesnopoyka,* both 1852), and, by reestablishing the vernacular as a medium for literature (the language of his translation of the Bible in 1862 is also based on Bulgarian dialects), he prepared for the flowering of native poetry. As a patriot and politician, he helped to shape resurgent Bulgaria, producing political pamphlets notorious for their outspokenness against Turkish oppression and against the spiritual domination of the Greek patriarchate. In 1863 he moved to Istanbul, where he contributed to Bulgarian *émigré* reviews and edited satirical and political periodicals. After his country's liberation (1878), he became an active politician, both as president of the constituent assembly and as co-founder of the Democratic Party. After the 1881 *coup d'état* he went to Plovdiv, then still under Turkish rule, and there edited the newspaper *Nezavisimost* ("Independence"). He died in Sofia on June 9, 1895.

Pencho Slaveikov, the youngest of Petko Rachev's eight children, was born at Trevna (Tryavna) on April 27, 1866. He studied literature and philosophy in Germany (1892–1908) and traveled widely despite being an invalid after 1884. Pencho Slaveikov, who was inspired especially by Goethe, Heine, and Nietzsche, as well as by the simple eloquence and realism of Bulgarian folk songs, is best known for his unfinished epic poem *Kurvava Pessen* ("Song of Blood"; written 1911–12; published 1913), which describes the sacrifices of the Bulgarian people in their struggle for independence. He was also an outstanding essayist and translator of German literature. He died on May 28, 1912, at Brunate, near Como, Italy.

BIBLIOGRAPHY.—*Izbrani proizvedenya* (1945) gives a selection of P. R. Slaveikov's poetry. Pencho Slaveikov's collected works have been edited by B. Penev, 7 vol. (1921–25). *See* also G. Hateau, *Panorama de la littérature bulgare contemporaine* (1937); L. B. Picchio, *Storia della letteratura bulgara* (1957).

(L. BY.)

SLAVERY is the social sanctioning of involuntary servitude imposed by one person or group upon another. Until the beginning of the 20th century, chattel slavery, involving the legal right of property, or ownership, generally was distinguished from other forms of servitude. But the progressively widespread prohibition of such slavery was accompanied by increasing resort to various practices and institutions to circumvent that prohibition. Therefore the concept of slavery has been broadened to include its possible substitutes which, while they do not necessarily imply the right of ownership of one person by another, nevertheless permit his exploitation under conditions of bondage. Some of these substitutes, such as indentured, or contract, labour and serfdom, have played distinctive roles in the history of civilization, at different times and places and within different cultures, and these historic roles are dealt with in separate articles (*see* CONTRACT LABOUR; SERFDOM AND VILLEINAGE). Similarly, movements to abolish the slave trade and slavery and its substitutes have had historical and political significance broader than the subject of slavery itself, and these are discussed in ABOLITION MOVEMENT; FORCED LABOUR; CIVIL LIBERTIES; and HUMAN RIGHTS, among others (*see* also biographies of leading abolitionists).

The main divisions of this article are as follows:

I. INTRODUCTION

An example of the broadened, 20th-century concept of slavery is offered by a 1947 decision of the Supreme Court of the United States (*United States* v. *Ingalls;* appealing the finding of a lower court that a California couple had enslaved their maid), in which the court examined the classical definitions of slavery based on the right of ownership and observed that they did not apply to the case under consideration. The court decided, nevertheless, that the appellant had been properly adjudged guilty by the lower court of having imposed slavery on "a person wholly subject to the defendant, . . . one who had no freedom of action and whose person and services were wholly under the control of defendant and who

was in a state of enforced compulsory service to the defendant." As will be seen, a similar concept was adopted by the League of Nations and even more so by the United Nations in the "Supplementary Convention on the Abolition of Slavery, the Slave Trade, and Institutions and Practices similar to Slavery" adopted in 1956.

Even from a purely historical point of view a definition of slavery broader than the one based on ownership would seem warranted. Although there is no doubt that in a great number of societies slavery was more or less modeled after the right that an individual could exercise over an animal or an inanimate object, enslavement as an economic and social phenomenon preceded the appearance of the concept of ownership. Indeed this concept could not come to the fore until the individual was clearly distinguished from the group as an autonomous centre of rights and obligations and thus recognized as a "person before the law." The primary fact was that a man made another work in his own interest; the idea that he had a right to do so came only later.

1. Origins of Slavery.—Explanations of the origins of slavery are necessarily speculative, constituting *post hoc* rationalizations. However, it would seem that through the hunting and food-gathering stages of civilization slavery would have been unknown; the hunter or food-gatherer simply would have had no use for a slave, who would have been more of a burden than an asset for his master, as he would have been an additional mouth to feed. This reasoning would seem to be supported by the fact that such hunters' societies as have survived into historical times, as for example those of most of the American Indians and of the Australian aborigines, do not seem ever to have practised slavery.

The situation apparently was similar in certain communities living mainly from fishing: Eskimos, for example, have never had slaves. But in other instances fishing tribes have had a more sedentary life, and certain tasks could, with some profit, be assigned to another, as, for example, making and repairing nets, canoes, etc. It is possible that this explains why a few slaves have been found in some fishing communities.

In any event, slavery as an institution definitely made its appearance when tribes reached the pastoral as distinct from the hunter stage. Even then it was modest as far as the number of slaves was concerned because the care of flocks required only a few hands. Furthermore, life was simple and there was little difference between the condition of a slave and that of the wives, sons, or daughters of his master, who were also subject to the latter's absolute authority.

The exploitation of slave labour increased at the agricultural stage. But as long as agriculture retained the character of a subsistence economy, slavery continued to bear on the whole the "patriarchal" or "domestic" character of the pastoral period.

2. Expansion of Slavery.—The real change in the character of slavery, as well as its expansion, came as a result of the change from a subsistence to a market economy. When large tracts of land fell into the hands of a relatively few wealthy landowners, and only one or a few staple products were cultivated, it was generally profitable to employ the labour of slaves working in large gangs. Under these conditions the slaves became an anonymous multitude, and their treatment was quite different and much harsher than when they still were considered members of their master's household. Examples of this type of "praedial" or "plantation" slavery will be found in other parts of this article (see *Slavery in Antiquity: Greece and Rome*; and *Modern* [*or Plantation*] *Slavery*, below).

When, on the other hand, the crops raised on large estates were more diversified, and husbandry was practised side by side with agriculture, it was often economically sounder to partition the land into small plots. In this case the method of exploitation led to serfdom rather than to slavery (*see* SERFDOM AND VILLEINAGE).

In the cities slaves were used not only in the domestic service of the master and of his family in all kinds of capacities, and exploited for the satisfaction of the master's lust or of his artistic tastes, but also for work in mining, industry, commerce, and the like. Slave girls staffed the brothels and filled the harems of the ancient world. There were also at times slave policemen and slave warriors. Among the latter some achieved great power and sometimes took the place of their masters and even founded dynasties. Such cases, of course, were exceptional and usually slaves were treated as an inferior class or caste. However, here again there were considerable variations from one society to another, and even in the same society according to the social function entrusted to them and often also in accordance with the circumstances which brought about their servile condition.

3. Sources of Slaves.—It would seem that individuals have been reduced into slavery mainly by capture, or force; as punishment for some offense; by birth from slave parents; by sale for nonpayment of debt; or by sale by parents, guardians, or chieftains.

Undoubtedly capture has been the most ancient source of slaves. And once the need for slave labour increased, expeditions were undertaken with the specific view of capturing human beings to reduce them into slavery. Thus slave raiding and kidnapping (*q.v.*) became the major means of supply. They were practised in antiquity as well as in modern times—until the end of the 19th century and perhaps even later.

Punishment for crime is also a very ancient source of slaves. When society took the right to punish for crime into its own hands, criminals usually became publicly rather than privately owned slaves, as in the case of condemned criminals sentenced to the galleys (*see* GALLEY). Although slavery of this kind seems to have disappeared, a certain analogy to it may be found in penal servitude, and perhaps also in forced or compulsory labour employed by some colonial powers and imposed by certain governments upon political opponents (*see* FORCED LABOUR).

A third source of slaves—birth—was the consequence of the acceptance of the idea that the slave was the property of his master. Consequently, the child born of slave parents belonged to their owner. However, birth has often been a less important source of slaves than one would imagine: in particular under the conditions of mass slavery such as those that prevailed on the Roman *latifundia*, and later on American plantations, there were usually a far greater number of men than of women among the slaves. Furthermore it was often more profitable to buy grown-up slaves than to wait until children reached an age where they could be put to work.

Another major source of slaves was sale. This needs some explanation. Insofar as slaves were considered as objects of property, they were subject to sale—and the main purpose of slave raiding was to supply the slave market. In these cases, sale is not considered as the source of slavery, as the individuals concerned already were slaves (by capture or kidnapping, birth, sentence, or prior sale).

In many societies, however, it has been possible for a free individual to sell himself, or a person under his authority—a wife or concubine, a child or grandchild, or a ward—into slavery for money or other consideration; or a tribal chieftain might sell individuals, families, or groups under his jurisdiction, or sanction their forced removal by traders.

Although the sale of persons into chattel slavery has been virtually eliminated, it must be stressed that practices leading to similar results frequently have outlived legal prohibitions. One such practice has been the sham adoption of children, especially girls, of extremely poor households by wealthier people who pay a certain price to the natural parent and thereafter exploit the child. Such practices were widespread even in the 20th century in China and other countries of Southeast Asia, where they were known under the Chinese name of *Mui Tsai* (little sister), and also in certain regions of South America, where the "adopted" child was frequently of Indian origin. Certain customs, in Africa, Australasia, and elsewhere, also may sanction the sale of a girl as a sexual partner by her parents, guardians, or clan. In the same regions a husband may lend any female member of his household to another man as a form of hospitality; and a husband's heirs sometimes may "sell" his widow or widows to other men.

Closely related to slavery resulting from sale is slavery resulting from the nonpayment of debt. In a considerable number of civilizations an insolvent debtor either became his creditor's slave, or could be sold by the latter to a third person. Here again cer-

tain practices have perpetuated in disguise this kind of enslavement even after its official legal abolition. Usually it takes the form of debt bondage, a condition arising from a pledge by a debtor of his personal services, or those of a person under his control, as security for a loan. The main feature of such an arrangement is that the value of services furnished is not applied toward the liquidation of the debt. Consequently the individual pledged has practically no hope ever to escape his servile condition. And, as it is not unusual in such cases that the debt remains due after the death of the original debtor, devolving on his next of kin, the servile station may become hereditary. Despite measures taken to put an end to servitude for debt, it has survived in many regions even in the second half of the 20th century. It occurs mainly in underdeveloped agricultural countries, but even economically more advanced countries have not been entirely exempt from it. In agricultural communities it often happens that the lender of money or credit is at the same time a wealthy local landlord—while the debtors are the impoverished farmers. (*See* also PEONAGE.) In more industrialized communities, the moneylender either directly exploits the debtor's labour for his own profit, or hires him out to some third party.

4. Lack of Opposition.—A last observation would seem to be in order. Although slavery in its various forms was an almost universal institution, or rather because of that, little or no opposition was raised against it. There were, of course, denunciations of its excesses, at times, and attempts to remedy abuses, but the existence of the institution was not questioned until the beginning of the modern antislavery movement at the end of the 16th and the beginning of the 17th century.

As late as the 11th century, St. Anselm stated that it was only natural that children born to slaves should follow the status of their parents, and St. Thomas Aquinas (1225–74) said that slavery was one of the inescapable consequences of Adam's original sin. And when, later, slavery was introduced into the New World, the Roman Catholic Church expressly recognized the validity of the institution, although Catholic missionaries made great efforts to mitigate some of its extreme consequences. The attitude of other Christian churches did not differ much from that of the Roman Catholic. During the first centuries most of the heretic or schismatic churches admitted slavery. Similarly, when after protracted disputes (451–1053) the Eastern or Greek Church broke away from the Church of Rome, it accepted slavery. Nor did even the Reformation change the attitude in regard to slavery. Both the Anglican and the Lutheran churches, and also the Presbyterians, accepted it as a fact. But, as shall be seen, religious feelings which inspired certain Protestant sects, and in particular the Quakers and the Wesleyans, were at the origin of the antislavery movement. *See* also ABOLITION MOVEMENT. (E. N. Go.)

II. SLAVERY IN ANTIQUITY

A. THE ANCIENT NEAR EAST AND EGYPT

1. Sources of Slaves in Antiquity.—Warfare was the earliest source of slaves in the ancient Near East and always remained a relatively important one. Originally captives seem to have been slaughtered; later women and then men were spared to serve their captors: the Sumerian word for slave woman means literally "woman from a foreign land," and appears at an earlier date than that for a man slave. Some prisoners passed into private possession, but most of them became the property of the kings (in Egypt all captives belonged in the first instance to Pharaoh), who either kept them or dedicated them to service in temples. The numbers of royal (state) and temple slaves thus created often grew considerably. Temples constituted one of the richest financial, commercial, and agricultural units within the communities, and slaves were often "dedicated" to the temples by kings or individuals hoping to secure thereby favours from the gods. They were the only large aggregations of slaves in pre-Classical times, and there seems to have been no equivalent of the great private slave households of Roman times (*see* below).

The supply of slaves by war was supplemented by purchase, usually from among neighbouring peoples. Certain tribes were famous for producing slaves of exceptional strength or beauty *e.g.*, the Gutian and Lullubu hill tribes, and merchants visiting these areas carried on a trade in slaves, but there is no evidence of specialized slave traders. How far the slave population recruited from these two sources was able to reproduce itself is uncertain. "House-born" slaves enjoyed a slightly higher social status, and masters often supplied their slaves with "wives" or "husbands" in order to obtain them. However, such unions had no legal force except among the Hittites. Children born to their masters by slave concubines fell into a different category (*see* below).

An important source of slaves lay within the native population itself. At least from the Third Dynasty of Ur in Babylonia (*c.* 2100 B.C.), and no doubt earlier, and from the Old Kingdom in Egypt (*c.* 2600 B.C.) self-sale or the sale of children in order to pay debts was widespread. Unlike the ordinary form of slavery debt-slavery was recognized as a social evil which should be held in check.

Many Babylonian kings, notably in the Old Babylonian period (*c.* 1800–1600 B.C.), issued decrees liberating debt-slaves and abolishing public and private debt. The Hebrew Sabbatical Year (the 7th) in which Israelite debt-slaves were to go free was paralleled in the law of Hammurabi (117), by which such persons were to be released upon completing three years' work for their creditor. It is not known how far and for how long these laws were observed, though Jeremiah castigates their evasion (Jer. 34:8–17). Poor Jews were forced to sell their children into slavery to pay their taxes after returning from the Babylonian Captivity (Neh. 5: 1–5). (*See* also BABYLONIA AND ASSYRIA: *Civilization: Slavery.*)

2. The Status of Slaves.—Slaves and freemen were not generally divided racially or culturally as they have been in more recent slave societies. Moreover between slave and freeman there existed a variety of semifree classes dependent on king or temple, and even free citizens were commonly liable to labour-service (*corvée*). Nevertheless, a slave was not a human being before the law, but a "head" like an animal. He seems to have enjoyed no protection from his master and if he was injured by someone else, the case was considered as one of damage to his master's

property. Hebrew law provided that if a master beat his slave to death and the victim lingered on for a day or two, the master went unpunished "for the slave is his money" (Ex. 21:20–21). In the circumstances, runaways were numerous, and in Babylonia the laws of Hammurabi prescribed death for harbouring a fugitive; other societies, notably among the Hebrews, were more lenient. Probably most masters found that it paid to treat slaves reasonably well, and sometimes inducements were held out to them, such as the privilege of retaining small gratuities, or the prospect of ultimate liberation. Manumission (freedom) was often granted on condition that the freedman (who was frequently adopted) should support his ex-master during his lifetime; any failure to do so led to reenslavement. The freedman thus was in an intermediate position between slavery and complete freedom; he might be required to remain for life or a definite time with, or perform some special duty or service for, his former master or a person named by him, and his failure or refusal to do so would subject him to being again reduced to slavery. Branding of slaves appears not to have been widespread. The reference, in ancient Babylon, to the "cleansing of the forehead" is probably symbolic; some slaves appear to have been tattooed, whereas others were distinguished by small clay tablets worn around neck or wrist. In Neo-Babylonian times, the owner's name was tattooed on slaves' wrists and temple slaves were often marked with a star, the symbol of the goddess Ishtar.

Female slaves were in a most vulnerable position. They might be prostituted against their will, and seem, as a consequence, to have formed an increasing proportion of the prostitute class. Alternatively they might be passed from one slave to another in order to breed more slaves. This latter was specifically provided for under Hebrew law (Ex. 21:2–11) and contracts from Nuzi (near modern Mosul), *c.* 1500 B.C., show that parents who were obliged to sell their daughters under the guise of adoption actually wrote such a clause into the contract, as a lesser evil than prostitution. A slave girl's best hope was to become her master's concubine. If her mistress were barren, her children might become legitimate heirs, and in any case her status was improved. Clause 171 of the laws of Hammurabi provided that a slave concubine and her children were to be released on her master's death.

The capacity of slaves to carry on business on their master's behalf was recognized, under rigid safeguards, in Babylonian times. By the Neo-Babylonian period (*c.* 620 B.C.), slaves carrying on business—as merchants, bankers, artisans, tenant farmers—and living on their own were commoner; some of them even owned slaves of their own. Any property acquired by a slave, however, remained legally the possession of his master, the slave making a payment for the privilege of engaging in business.

The status of freedmen is unclear. Both in Egypt and Babylonia, slaves liberated by adoption seem to have acquired the status of their adoptive parents, and thus might become citizens. This can hardly have been so in the case of the free but illegitimate children of a master and his slave concubine, or of slaves manumitted in other ways.

3. Economic Importance.—Slaves were to be found in almost every field of work in pre-Classical antiquity, but in the absence of reliable statistics it is impossible to estimate the economic importance of slave labour. The number of slaves in Egypt before the wars of the New Empire (*c.* 1560 B.C.) was probably insignificant and they were by no means without rights. Those attached to the land, however, were sold with it, although the Egyptians do not appear to have used the word "slave" of persons attached to the soil, as much of the population was. Elsewhere numbers were larger and tended to rise. Maximum figures for slaves in private households rose from 20 or more in Old Babylonian times to over 100 a millennium later under the Assyrian Empire (745–612 B.C.). Averages were far smaller and only the well-to-do could normally afford slaves at all. Prices rose steadily despite increasing numbers, and kept pace with the rise in prices generally. Most privately owned slaves in cities were domestics; in the country they worked alongside their masters in the fields. They seem never to have presented a threat to the existence of free tenant farmers, though true slave farmers existed on large estates in the Assyrian Empire, and could be bought and sold either with the land they worked or separately. This was probably exceptional, because of the conditions of the period. Slaves seem to have been rarer in skilled trades and professions, though slave apprentices are mentioned, especially in Neo-Babylonian times, in contracts concluded between their owners and master craftsmen. Skilled workmen were also to be found among the temple slaves, but were probably exceptional there also. In general, craftsmen were freemen. It seems certain, therefore, that any threat to the economic conditions of free persons by slaves was confined to the unskilled, and it can only have been acute in times of an over-abundant supply of labour, but to judge from the retention of unpopular forced-labour service, a shortage of labour was much commoner. (D. G. E.)

B. Greece and Rome

Slaves are mentioned in the Homeric poems, which probably reflect the conditions of the early first millennium B.C., and play a prominent role in the legal code of Justinian (A.D. 527–A.D. 565). During these 15 centuries slavery was an accepted institution, never seriously challenged. In the 5th and 4th centuries B.C., it is true, philosophers questioned slavery, like all other fundamental human institutions, such as the state and the family. As Plato was not interested in the problem, we know little of the debate, but it appears from Aristotle that some philosophers declared that slavery was contrary to nature, and therefore unjust. Aristotle himself took an opposite view. According to him, many—indeed the majority—of the human race lacked those higher qualities of the soul which were necessary for freedom. Slavery was not only good for the master, who was provided with living instruments, but for the slave, who received guidance which he was incapable of providing for himself. Aristotle admitted that in practice men free by nature (*i.e.*, the Greeks) were enslaved "by accident," and natural slaves (*i.e.*, barbarians) were allowed to be free; but although the institution was not always properly used, it was fundamentally natural and good. Later philosophical schools, like the Cynics and Stoics, who preached the brotherhood of man, held that slavery was contrary to nature, but they did not therefore suggest its abolition. Freedom and slavery, like all material concerns, were, they taught, matters of indifference. To Christians, there were neither bond- nor freemen in Christ, but in this world they counseled masters to be kind to their slaves and slaves to be obedient to their masters. The doctrine of the Roman law was summed up by Justinian in the sentence, quoted from the 2nd-century lawyer Florentinus: "Slavery is an institution of the *ius gentium* (law of nations), whereby a man is, contrary to nature, subjected to the ownership of another." No other legal institution is expressly admitted to be contrary to natural law; but after this formal acknowledgment of philosophical theory, the Roman lawyers plunged into the practical rules governing slavery without demur.

1. Sources of Greek and Roman Slaves.—The sources of slaves were many and varied. In primitive Athens and Rome insolvent debtors might be enslaved by their creditors. This was forbidden by Solon at Athens in the 6th century B.C., and in the late 4th century B.C. in Rome, but the rule probably prevailed longer in many communities. With the extension of Roman law (*q.v.*) to the whole empire, slavery for debt ceased to be legal. In Greece children exposed and abandoned by their parents became the slaves of those who reared them. Roman law varied on this point until Justinian in the 6th century declared that all exposed infants were free. Poor parents also sometimes sold their children. This was prohibited by Roman law, but was nevertheless not uncommon, especially under the later empire; the sale of newborn infants was legally recognized by Constantine the Great. A free man might, under Roman law, allow himself to be sold into slavery, and could not reclaim his freedom if he was over 20 and had received a part of the price paid for him. A few offenses were punished both in Greece and Rome by sale into slavery, and under the Empire a common penalty for crime among the lower orders was slavery in the state mines and quarries.

The principal sources of slaves, however, were war, piracy and

kidnapping, breeding, and import from barbarian lands. Victors in war always possessed, and frequently exercised, the right of selling captives. In Greece combatants taken in battle were frequently ransomed, but when a city was captured the whole population was often sold into slavery. Since wars were constant many Greeks were thus enslaved. Piracy also flourished unchecked except while Athens policed the sea. But the majority of slaves in classical Greece were barbarians imported by traders, mainly from Asia Minor and Thrace and the Black Sea area. The supply from these sources was abundant and prices were low—an unskilled adult male seems to have cost a sum roughly equivalent to a year's maintenance. In these circumstances few slaves were bred, slaves being more cheaply replaceable by purchase. Female slaves in domestic service bore children to their masters and fellow slaves and the children were no doubt often reared as slaves. The majority of slaves, however, were men employed in agriculture, industry, and mining.

In the Hellenistic period (323–30 B.C.) wars were frequent and widespread, and piracy was rife. While Rome was conquering the Mediterranean world, wars increased in scale and became more ruthless and thousands of captives from Spain, Gaul, Africa, Greece, and the East were flung upon the market. With the decline of Rhodian sea power after 167 B.C., piracy flourished on a scale hitherto unknown, until in 67 B.C. Pompey cleared the seas. Slaves were imported on a vast scale to Italy and were used in ever increasing numbers in agriculture and mining.

With the establishment of the principate (27 B.C.) conditions changed. Under Augustus there were still wars of conquest and many thousands of barbarian prisoners were enslaved, but thereafter large-scale wars were rare. Peace reigned within the empire, piracy and brigandage were effectively suppressed and without these two major sources, slaves could be imported only from beyond the Rhine, the Danube, and the Euphrates. In the circumstances slaves became scarcer and their price rose; by the 2nd century A.D. they seem to have cost—in real value—eight to ten times as much as in Athens of the 4th century B.C. Breeding in these circumstances became necessary and profitable. Cato, in the 2nd century B.C., had permitted the bailiffs of his estates to keep wives, but had allowed no other women slaves on his lands, replacing the labourers by purchase. From records of the 2nd century A.D. it appears that fertile slave women were valued and commanded a higher price.

From the 3rd century onward wars with the barbarians revived and increased in intensity, bringing in their harvests of prisoners. These, however, were not always thrown upon the slave market; the government often preferred to enroll them in the army or to settle them on the land as free men, liable to military service. Many thousands of Roman citizens were, moreover, carried off as prisoners by barbarian raiders. Many were ransomed by their relatives or by the church, but a large number were reimported into the Empire as slaves, and although they were legally entitled to recover their freedom on repayment of their purchase price, most were unable to do so. In these circumstances the price of slaves dropped to about half of what it had been in the 2nd century, but slaves remained very substantially dearer than they had been in classical Greece or under the later Roman republic. It was still more economical to breed slaves than to buy them.

2. Economic Importance.—There were few activities which were not common to free men and slaves. The latter were, of course, excluded from political life and only citizens could hold magistracies (public office). Slaves were, moreover, excluded from military and naval service; only in moments of extreme crisis were slaves enrolled in the armed forces, being freed for the purpose. Domestic service, however, was reserved for slaves; it is almost unknown in classical antiquity to find a free man as a personal servant. It is often stated on the basis of statements in Plato, Aristotle, and Cicero that the Greeks and Romans regarded manual work, with the exception of agriculture, as degrading for free men and only fit for slaves. The great majority of Athenian citizens, however, were either peasants, craftsmen, or labourers, and felt no shame in the fact; they worked even in the mines. But while the hardest manual labour was tolerated, any employment which involved being subject to another man's orders was considered servile and degrading, even if the work was managerial and not manual. This attitude seems to have been universal in the Greek and Roman world and it had far-reaching effects on the economy.

It meant in the first place that slaves (or freedmen) were normally employed in secretarial and managerial posts. In 4th-century Athens, bank managers were often slaves or freedmen of the bank owners. Within the sphere of agriculture the bailiff, who was directly responsible to his owner, was normally a slave, even though the estate was worked by free tenants and free casual labour. In the early principate in Rome a curious anomaly arose. The emperor's principal secretaries and accountants, who were slaves or freedmen, inevitably became politically influential and important, and came to do the work of secretaries of state and ministers of finance. This situation caused great bitterness among the senatorial aristocracy; but it was only after a century that the problem was solved, when the offices of the imperial household came to be regarded as public rather than as domestic posts and became acceptable to members of the equestrian order, though not to senators.

Secondly, it was virtually impossible for any industrial enterprise to expand beyond the scope of a household business without the use of slave labour. A free man would accept casual jobs, usually on a contract basis, but he was generally unwilling to submit himself to regular work under a master's orders. A craftsman might employ members of his family and perhaps apprentices, but if he wished to expand his business he had to buy slaves. Except when slaves were very cheap, this meant a heavy and risky capital outlay, and as a result industry tended to be on a small scale, unless conditions were exceptionally favourable, as in mining.

There are no reliable figures for the number of slaves, either absolute or relative to free persons, but it is clear that numbers varied very greatly in different periods and areas according to the wealth and economic development of the receiving areas and the availability of alternative forms of labour. In classical Greece the Spartans had few slaves, since there was a serf population, the helots (*q.v.*), that not only cultivated the lands of the Spartans but provided them with personal service. In the more backward parts of Greece, such as Arcadia and the northwest, the majority of the population were peasants and neither needed nor could afford many slaves. Even in so rich and economically progressive a city as Athens the great majority of the free inhabitants were peasant proprietors or independent craftsmen and shopkeepers. The more prosperous of these might own one or two domestic servants, farm hands, or assistants in the workshop, but the majority probably had no slaves. Richer families had larger domestic staffs, and landowners normally cultivated their home farms and sometimes all their estates by slave labour. In industry there were factories of 20, 30, and even 120 slaves. The silver mines of Laurium were almost entirely worked by slave labour, and at times employed as many as 10,000–20,000 men. Some rich Athenians invested largely in slaves; Nicias, the 5th-century-B.C. general, is said to have owned 1,000, whom he hired out to mining contractors at a fixed daily charge. Many well-to-do Athenians owned a few slave craftsmen, whom they either leased to an entrepreneur or allowed to work independently, paying their masters a fixed revenue and keeping their other profits for themselves. Such slaves, who "lived separately," might *de facto* acquire property or incur debts, and could be sold as going concerns with their assets and liabilities. The city of Athens owned public slaves, including the famous corps of Scythian police, and others ranging from street cleaners to the public executioner and the chief accountant and keeper of the records.

Slavery reached its high-water mark in Rome in the 2nd and 1st centuries B.C. Not only were slaves very abundant and cheap, owing to the prevalence of wars and piracy, but the Roman upper classes were immensely wealthy and were building up huge estates (*latifundia*). The result was the introduction of agricultural slavery on a vast scale. The peasantry were progressively expropriated, and their lands either cultivated by slave gangs or converted into ranches manned by slave herdsmen. This is the only

period of antiquity in which large-scale slave revolts occurred, in Sicily in 135–132 B.C. and 104–100 B.C., and the rising of Spartacus (q.v.) in Italy in 73–71 B.C., and the difficulty with which these revolts were suppressed proves the large numbers involved. Slaves were also employed on a vast scale in the mines; there are said to have been as many as 40,000 in the silver mines of New Carthage in Spain.

Under the principate there was a recession as slaves grew scarcer and prices rose. On estates already manned with slaves the stock was often maintained by breeding, but landlords generally preferred to lease their lands in small holdings to free tenants, retaining slave labour only on a home farm; vineyards were commonly cultivated by slaves (the vintage being undertaken by casual hired labour or by a contractor who purchased the hanging crop), since tenants were not trusted to do the skilled work involved. Even in the mines slave labour declined. Some were worked by convicts; others were no longer leased *en bloc* to contractors but let by shafts to free working miners; in others, free indentured labour was employed. Slaves were now predominantly used in domestic service, in managerial and clerical posts, and in skilled crafts. The secretarial and financial offices of the imperial government were manned by slaves and freedmen of the emperor, who came to form a hereditary group. The *Digest* (Justinian's collection of jurists' opinions) reveals that landowners normally employed slave agents and bailiffs, and that wealthy men owned slaves engaged in commerce and industry. Rules of law were worked out to determine how far a master was responsible for the financial transactions of shippers, merchants, shopkeepers, and craftsmen whom he owned. He could, provided that he gave due notice of the fact, disclaim liability for the debts of his shopkeepers and craftsmen, and the creditors could recover only from the latters' *peculia*, the money or stock which their owner had allocated to them. Slaves were predominantly used in responsible and skilled positions, where their special usefulness or higher earnings would repay the cost of training. In the later Empire, despite the fall in the price of slaves, the position did not substantially alter. In some areas there were hereditary groups of agricultural slaves who could not legally be sold apart from the land; their status in law and practice more and more resembled that of free tenants, who on their side were being converted into serfs and were bound to a given piece of land. Convicts were used in certain state quarries, but miners were, in general, free men. The chief innovation of the age was the establishment by Diocletian, in the 3rd century, of state weaving and dyeing factories, manned by slaves; but by the 4th century these slaves had become hereditary groups whose status differed little from that of free men.

3. Social Conditions.—It is obviously impossible to generalize on the condition of slaves in classical antiquity. All slaves were liable to the arbitrary cruelty of their masters; their only legal remedy was to escape to a sanctuary and demand to be sold to another master. Antoninus Pius (A.D. 138–161) ruled that the killing of a slave by his master was homicide, but Constantine absolved the master if the slave died as a result of flogging. In practice there were great differences between various categories of slaves. In the mines slaves were often ruthlessly worked to death, and the chained gangs on the land were brutally treated. On the other hand a private secretary or a nurse might be treated as one of the family, and a craftsman in charge of a workshop or a sea captain in command of a ship enjoyed *de facto* most of the rights of a free man. Miners and agricultural slaves had little hope of freedom, while domestic servants could reasonably hope to be manumitted, and craftsmen and shopkeepers had a fair chance of buying their freedom.

The fact that slavery was universally accepted as a normal social institution made relations between slaves and masters easier. Slavery was regarded as a misfortune but not as a wrong, and slaves felt no resentment against their masters unless they were ill-treated. There was, moreover, no distinction of race or colour between slaves and freemen. In classical Greece most slaves were barbarians, but there were many Greek slaves (although no Greek was a slave in his own city) and free barbarians, and there was no marked racial or cultural cleavage between the Greeks and the neighbouring barbarian peoples. In the Roman Empire slaves were for the most part from the same stock as the provincials. Nor was there any marked distinction in the kind of work done by freemen and slaves. There were slaves in the professions and skilled trades, and free manual workers. Slaves were not distinguishable by dress or any outward mark from free persons in the same walk of life, and the intermarriage between slave and free, though legally null, was not uncommon in the lower ranks of society. A manumitted slave did not in Greek cities become a citizen, citizenship being a strictly hereditary privilege, but he ranked like any other resident alien. In Roman law he became a citizen if manumitted in proper legal form, though he did not enjoy full civic rights, being ineligible to serve in the army or to hold public office or become a city councilor. (A. H. M. J.)

III. SLAVERY IN THE OLD WORLD AFTER THE FALL OF THE ROMAN EMPIRE

1. Western and Central Europe.—Although slavery declined notably at the end of the Roman Empire, it did not disappear even in Western and Central Europe, and, although it never again reached the importance it had in Rome during the classical period, there were times when the institution was definitely on the upsurge. The first increase in the number of slaves occurred as a result of the barbaric invasions because it was customary for various Germanic tribes to reduce enemies captured in battle into slavery. The conversion of the various kings to Christianity made little difference in this respect since, as we have seen, the Church did not proscribe slavery. A second upsurge of slavery seems to have occurred between the 8th and 10th centuries when many Slavonic peoples were captured and taken as slaves to Germany. (The very origin of the word "slave" is explained by this circumstance.) At that time slaves were often given to churches and monasteries by wealthy and pious people. However, from then on slavery definitely declined in Western and Central Europe, and although no definite date can be indicated, it seems to have disappeared in these regions toward the end of the 13th century, when, under the feudal system, serfdom took its place.

2. Southern Europe and the Middle East.—But the situation was very different in the East and South. For one thing slavery had continued under the Byzantine Empire. Furthermore the appearance of Islam gave a new impetus to the institution. Mohammed found slavery well established in Arabia when he began to preach the new religion in the first years of the 7th century. His attitude toward it as revealed in the Koran was very similar to that of the Christian churches: without condemning slavery, he taught that slaves should be treated with humanity and that the liberation of a slave was a pious and meritorious act.

But the appearance of Islam was followed by wars of conquest that covered vast areas in Asia, Northern Africa, and Eastern and Southern Europe. After the Arabs came other Islam invaders, including the Ottoman Turks. All these wars led to the capture of numerous prisoners, often reduced to slavery, although usually the civilian population was left free on condition of paying taxes to the conquerors. During the Crusades, Christians also enslaved many of their Saracen and other Muslim prisoners. This brought about a considerable increase in the slave traffic, not only in Muslim lands, but in Christian Europe as well. Even the Church's strenuous efforts to prevent the sale of Christians by Christians were not always successful: Hanseatic, Venetian, and Genoese slave traders bought Syrians, Serbians, Bulgarians, Armenians, and others from the Turks and resold them elsewhere. The fall of Constantinople in 1453 was followed by a marked increase of sales. Another source of slavery in Muslim lands was the capture of seamen and passengers in the Mediterranean by buccaneers operating from North Africa. "Slave charities" were established in England and other European countries to redeem these Christian prisoners and diplomatic efforts were made to curb the Muslim slave trade. Muslim slavers also raided territories in various parts of Black Africa, or purchased slaves from African chieftains.

However, it must be noted that slavery in Muslim countries, which continued throughout centuries and survived legally, or at least in custom, in a few of them, has always been very different

from that which existed in Rome and in the Americas after their colonization by Europeans. Gang-slavery for work in the fields or in industry and mining was almost unknown in the Islamic world. Most of the slaves were employed in wealthy households for domestic service and were well treated, in accordance with the prescriptions of the Koran. The one really cruel Muslim institution was that of the eunuchs, which involved emasculation. Women slaves in harems became their masters' concubines, or even legitimate wives (*see* CONCUBINAGE). Furthermore, Muslim society was not usually in the least race- or colour-conscious. Liberated slaves of whatever origin were readily absorbed as equal members of the community and examples of slaves or former slaves reaching the highest positions were numerous. Perhaps the most famous example of all is the case of the Mameluke slave dynasty which ruled Egypt for more than two and a half centuries (1250–1517), during which period one slave ruler succeeded another in the same way as normally a son succeeds his father.

In countries of the Iberian peninsula, Spain and Portugal, slavery continued to exist, not only through the period of Arabic or Moorish dominance, but also after their reconquest by the Christians in the 15th century. Naturally, the defeated Muslims were the first to be reduced into slavery. But soon the Portuguese set out to import slaves from Africa as well. The first Negro slaves were imported in 1444 by Portuguese captains of Prince Henry the Navigator, who had obtained them as ransom in exchange for Moorish prisoners. Later the Portuguese engaged directly in the slave trade and established factories (trading posts) for that purpose on the coast of Guinea.

Negro slaves were imported in ever increasing numbers into southern Portugal and neighbouring regions of Spain, where Seville became an important slave market. These regions had greatly suffered from wars between Christians and Muslims and their populations had been largely depleted. Imported Africans were employed not only for service in wealthy households, but also for work in the fields, and for a variety of tasks in the cities, especially as stevedores in the harbours. Because the Portuguese, and to a lesser degree also Spaniards, as a result of the many conquests, had little race- or colour-consciousness, the various elements of the population mixed relatively freely and ultimately merged.

IV. MODERN (OR PLANTATION) SLAVERY

1. Early Developments in the New World.—Records show that Christopher Columbus and his companions in the course of their several voyages took a few Christianized Negroes born in Spain to Hispaniola, the first European colony in the New World. It would seem that at the time there was no conscious design to set up Negro slavery in the newly discovered lands. On the contrary, the European settlers first endeavoured to use the native Indian population as labour. In this connection it may be observed that if slavery was not a general institution in the Americas before the arrival of Europeans, it certainly existed in some regions, and particularly in parts of Central America. For example, Cortés has left a description of the great market place at Tlaltelolco (present Mexico City), and of the large number of male and female slaves brought there "for sale as the Portuguese bring Negroes from Guinea." The Spaniards themselves shipped a number of captured Indians to the home country, either as a present for the sovereigns, or for sale. In America, however, Indians were generally subjected by the Spaniards to institutions more reminiscent of serfdom, such as *repartimiento* or *encomienda*, considered more suitable for agricultural exploitation, than to chattel slavery. Only in the mines was the situation different and more akin to outright slavery.

Whatever the case, difficulties arose. Firstly, Indians proved to be less docile than had been thought and sometimes rebelled, or more often disappeared in the surrounding forests. Secondly, they often lacked physical vigour and succumbed in large numbers to diseases brought over from Europe. In addition, their employers found themselves at odds with the Roman Catholic missionaries. The missionaries' main preoccupation was the evangelization of the pagan population, and consequently they wanted it to be treated gently. The Spanish king, Ferdinand the Catholic, adopted a solution midway between the desires of the settlers for abundant and cheap labour and the much more lenient attitude of missionaries: Indians could be forced to work, but only under certain prescribed conditions, including humane treatment and the payment of a remuneration. But, of course, the last prescriptions of the edict were often disregarded. It is for this reason that Bartolomé de Las Casas, Roman Catholic bishop of Chiapas, approached the new king, Charles I (Emperor Charles V of Germany), with the proposal that each Spanish settler should be permitted to bring over a certain number of Negro slaves. In 1517 this idea was accepted, although in somewhat modified form, and a Spanish nobleman was granted, by letters patent, a licence to import each year a specified number of Africans into Hispaniola on the condition of paying duties to the royal treasury. Soon thousands of Negroes were brought, not only into Hispaniola but also into the other islands of the Caribbean and later to the mainland. Thus a measure of mercy conceived for the protection of Indian natives became the origin of one of the cruelest institutions of all time—Negro plantation slavery. Las Casas soon discovered his mistake and expressed his regrets concerning it in his *History of the Indies*.

The establishment of Negro slavery did not put an end to the exploitation of Indians and both forms of servitude existed side by side. In the Spanish possessions on the mainland, the servitude of Indians was prevalent; from it evolved peonage (*q.v.*). Certain remnants of this condition survived as late as the second half of the 20th century, thus outliving the abolition of chattel slavery. On the other hand, in the Caribbean island colonies, not only of the Spaniards, but also of the British, French, Dutch, and Danes, the aboriginal Indian population suffered total extinction in the course of time. There Negro slavery prevailed and, with the development of sugar plantations, assumed colossal proportions from the end of the 17th century.

Similar events occurred in Brazil, after the coast of that country fell under Portuguese domination. In Brazil, however, Indian aborigines were directly enslaved in large numbers with perhaps even more inhumanity than in Spanish possessions; in addition to the exploitation of the Indian population along the coast, the manhunt was pursued deep in the jungles. Jesuits and other Roman Catholic missionaries there, too, took the aborigines under their protection, an arrangement confirmed by the king of Portugal who set up a council of missions. But this did not prevent further enslavements, often under the very eyes of the missionaries. However, when sugar and later coffee plantations developed on the vast *latifundia*, the Portuguese adopted the same solution as the Spaniards and imported Negroes as slaves in ever increasing numbers.

Thus, the development of the institution of slavery in Central and South America (and later also in parts of North America) was intimately connected with the growth of the plantation economy. Negro slaves also worked in the mines, as stevedores in the ports, and in other heavy work; served as domestic servants of all kinds; and were trained in various trades. But it was after the development of sugar plantations that the slave trade between the West Coast of Africa and the Americas reached enormous proportions, becoming the most lucrative trade of the time and constituting a considerable proportion of traffic as a whole.

2. Growth of the Triangular Slave Trade.—The English became the most important importers of slaves, although the French, the Dutch, and others also took part in the commerce, to supply their own colonies or the larger and richer Spanish posses-

sions. On the other hand the Portuguese reserved the monopoly of traffic to Brazil to their nationals.

This trade was usually triangular. Ships set out first from a home port such as Liverpool or Bristol in the case of the British for the Atlantic Coast of Africa. They carried liquor, firearms, cotton goods, and various trinkets that were exchanged for slaves brought from the African hinterland to one of the numerous factories established along what became known as the Slave Coast (Gulf of Guinea). Then came the so-called "middle voyage" from Africa toward the West Indies or one of the colonies or countries on the American continents: this leg of the trip was the slave trade proper. Although usually shortened by favourable winds, it represented a true torture for the involuntary passengers. They were closely packed in the hull to save space and often chained in order to avoid rebellion, or prevent them from jumping into the sea. Even by standards of the time, food was inadequate and water scarce. There was no proper ventilation, nor were sanitary installations provided. The only consideration which could lead to somewhat better conditions was the greed of slave traders and their desire to bring as many slaves as possible to destination in a condition which would permit their sale. But even this consideration had little effect if the ship, for one reason or another, was delayed. In such a case the mortality among the human cargo could reach appalling proportions. If a severe storm came and it was necessary to reduce the load, the sick were thrown overboard and at times also the healthy, especially, as was often the case, if the "cargo" was insured. It has been calculated that at least 20% of all the Negroes transported did not survive the voyage. Once they arrived at their destination, survivors were either directly delivered to their prospective employers or more often kept in stockades to await a purchaser. The ship then undertook the third and last leg of the voyage—homeward—loaded with the various staples produced on the American plantations. One of the chief items of the trade was molasses, from which rum was distilled and used for the purchase of more slaves on the next trip. If all went well, the profit was enormous. It was carried in bullion or in bills of exchange on banks in the home country. Later, when New England ports developed, their traders also engaged in the triangular trade, which proceeded on the lines described above, except that Boston or some other North American city was substituted as home port. The number of slaves transported under these conditions amounted to over 2,000,000 from 1680 to 1786 for the trade to British possessions and the West Indies alone. Another source indicates for the year 1790 the following figures: 38,000 in British ships; 20,000 in French; 4,000 in Dutch; 2,000 in Danish; and 10,000 in Portuguese, or a total of almost 75,000 for a single year.

3. Treatment of Slaves.—What was the treatment meted out to those of the slaves who reached their destination or to those who were born in captivity? The reply to this question is not simple because a considerable number of factors must be taken into consideration.

In the first place, each of the colonial powers had its own standards and policies, which varied widely. By way of generalization it may perhaps be said that slaves fared better in colonies of Catholic and Latin nations than in those of Protestant countries. One reason for this is that the link between the mother country and its dependencies was much closer for the first group than for the second. Consequently, the metropolitan authorities, through their agents, tried to exercise at least a minimum of control over planters. These countries, namely Spain, Portugal, and France, promulgated detailed laws concerning the treatment of slaves, of which the most famous is the French *Code Noir* (Black Code) put into force by King Louis XIV in 1685. This compilation contained a number of relatively mild prescriptions, however, often disregarded. Even more liberal was the Spanish Slave Code promulgated in 1789. In the British possessions, on the other hand, white settlers often were granted self-government. Consequently they were free to promulgate regulations as they saw fit. These were often extremely stringent, as in the case of the Barbados Code, imitated in Virginia and elsewhere. However, beginning with the last years of the 17th century, under the impact of the antislavery movement both at home and in certain American colonies, improvements were sometimes introduced in the British dependencies.

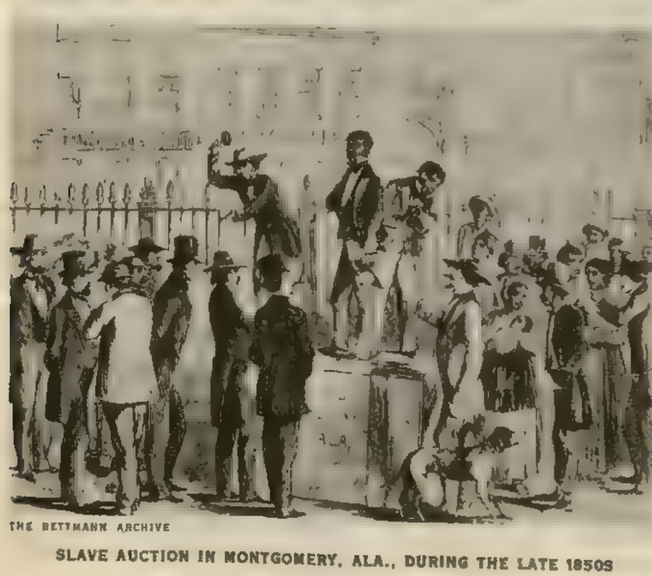
Another factor affecting the situation of Negro slaves in the colonies of Roman Catholic nations was the interest taken in their lot by the clergy. One partial expression of its influence was the enactment of already mentioned codes by metropolitan authorities. But the Roman Catholic clergy also tried to exert its authority on slaveowners on the spot. For example, it encouraged church marriages for slaves and opposed the separation of families. On the other hand, the Anglican clergy did not seem to show similar interest in the slaves, and in many British possessions and U.S. states the law expressly prohibited legally binding slave marriages. But here too the situation in some cases changed under the influence of the Quakers and of certain Protestant dissidents.

A third difference came as a result of the attitude of the peoples themselves. As already noted, the Portuguese and Spaniards had no race or colour prejudice. Miscegenation between white men and Negro women was, of course, a common phenomenon in all colonies. The rule everywhere was that the child followed its mother's condition, and consequently was born a slave. It was customary, however, in Roman Catholic lands for the master to grant manumission to his child, and sometimes also to the mother. Manumission was also frequently granted for long and devoted services of a domestic slave, in particular to nurses who had looked after the master's children. As a result, for example, in Haiti under French domination, a class of free and relatively well-to-do mulattoes gradually emerged. In Brazil, where toleration toward the half-castes and even full Negroes was much more in evidence, a number of free persons of African descent had reached positions of eminence even before the liberation which came in 1889; this, in turn, fostered still more the spirit of nondiscrimination and had its effect on the condition of slaves, particularly those in direct contact with their masters. It would be excessive to say that in Anglo-Saxon territories, including the Southern United States, similar situations never occurred. But there the colour line was drawn once and for all, and a person having even a small strain of African blood was a Negro, whether slave or free. In addition some of the colonial statutes prohibited manumission, or made it extremely difficult.

What is certain is that the condition of slaves in all countries depended greatly upon their position and the tasks they had to perform. Those in domestic service were usually a kind of privi-

leged elite, although here again there were many gradations depending upon the nature of the job, the character of the master, and personal qualities of the slave himself. The next category was that of slaves exercising various trades. The third—and most numerous—included the slaves working on plantations. Here is where one could find the worst excesses, particularly if the estate was large and the absentee landowner had to rely on an agent who hired supervisors. Nonetheless, in order to maintain a balanced picture, one must always remember that published accounts usually concerned either the best or the worst examples. Probably on the whole the situation of slaves was not much worse than that of indentured labourers brought over from Europe (*see* CONTRACT LABOUR). At times it might have been even better because the master had reason to take care of his slave, who represented capital, whereas he had no similar incentive in regard to the labourer. But, of course, the condition of the slave was permanent and even hereditary, whereas an indentured man retained important rights under colonial laws, and became free at the expiration of his contract. Furthermore, the condition of slavery itself was degrading. This was keenly felt by many Negroes, particularly those who had been brought over from Africa and sold into slavery; a person born into slavery was more likely to accept his condition with resignation. But rebellion was an ever-present threat, and uprisings occurred from time to time in various parts of the slave world—in Brazil and Haiti (which thus gained its independence from France), for example, and also in the British possessions. Nor was the danger absent in some of the Southern U.S. states, although the Civil War proved that it had been greatly exaggerated: during the entire period Southern slaves showed a surprising passivity and toward the end some of them were even called upon to serve in the forces of the Confederacy.

4. North America.—As concerns the introduction of slavery in North America, and in the United States in particular, it must be remembered that various parts of the country had originally been colonies of different European states: England, Holland, France, and Spain. Thus during the colonial period different slave codes prevailed. In the North American English possessions each colony decided for itself, but there was, of course, imitation of one by another. What is more striking is the fact that Negro slavery as a systematic institution appeared on the mainland relatively late: the first shipload of slaves arrived, almost by chance, in Virginia in 1619, and then in a Dutch and not a British ship. At first slavery developed extremely slowly and in Virginia in 1681 there were still only 2,000 Negro slaves as against 6,000 indentured labourers of European origin. It was only after the intensive cultivation of tobacco developed, and a little later also of rice, that slavery took root in the colony, so that the number of slaves reached 59,000 in 1714. From then on it increased steadily, mainly through new arrivals, reaching 263,000 in 1754. But a few years later the increase slowed down and at the time of the American



THE BETTMANN ARCHIVE

SLAVE AUCTION IN MONTGOMERY, ALA., DURING THE LATE 1850S

Revolution it even seemed that slavery might gradually disappear. The reason was that tobacco rapidly exhausted the land on which it was grown, so that it had to be used for other crops, by far less profitable. It was only with the introduction of cotton, and particularly after the invention of the cotton gin in 1793, that the trend was once again reversed and the number of slaves increased steadily till it reached the figure of almost 4,000,000 on the eve of the Civil War in 1860.

The history of the antislave movement in the United States and the sequence of events that finally brought about the emancipation are examined below. It is proper to note here that since the beginning of the 19th century the United States, from the point of view of slavery, was divided into three zones: in the North, where the economy had never been based on that institution, and which became more and more industrialized, slavery was legally abolished between 1777 and 1804 by action of the individual states; in the cotton-producing South slavery not only existed but was greatly expanded; in between was a belt of "border" states which also legally maintained the institution of slavery, but in which the number of slaves was continuously on the wane because the economy no longer had use for slave labour.

V. THE ANTISLAVERY MOVEMENT AND ABOLITION IN THE WESTERN HEMISPHERE

1. Great Britain.—The beginnings of the antislavery movement in Great Britain may be traced back to the last third of the 17th century. In 1673 Robert Baxter, a nonconformist, published his *Christian Directory* in which, without condemning slavery, he vigorously attacked the slave trade. In 1680, Morgan Goodwyn, an Anglican clergyman, described his sojourn in Barbados and the treatment inflicted upon the slaves in that island colony. Mention should also be made of the antislavery pronouncements of George Fox (1624–91), the founder of the Society of Friends, or Quakers.

During the same period appeared Aphra Behn's novel *Oroonoko* (1688), later dramatized by the poet Thomas Southerne (1696), describing the miseries of the slaves brought over from Africa to the West Indies. The novel and the play had considerable impact on the public. Perhaps an even greater influence should be ascribed to John Locke, who attacked the institution of slavery in his *Treatise on Civil Government* published in 1690.

In the following years slavery in general and the African slave trade in particular were denounced by Sir Richard Steele, Alexander Pope, James Thomson, William Shenstone, John Dyer, Richard Savage, William Cowper, and many others. In connection with slavery in the British colonies on the American mainland, special mention should be made of the Quakers John Woolman (1720–72) and Anthony Benezet (1713–84), who was of French Huguenot origin. The latter in particular exercised his influence on both sides of the Atlantic and many of the English abolitionists were his disciples.

One of the practical problems which arose in England at the beginning of the 18th century concerned the status of slave servants brought into the mother country by planters. The controversy reached its peak in 1729 when in a legal opinion the Attorney General and the Solicitor General pronounced themselves in favour of the doctrine that a master could compel his slave to return to the colony. Chief Justice Sir John Holt (1642–1710) had held the opposite view. The matter was settled only in 1772 by the famous decision of Lord Mansfield in the case of the Negro Somersett. According to this decision a slave became a free man the moment he had set his foot on the soil of the British Islands. This decision was hailed as a victory by English abolitionists; but it had not the least effect upon either slavery practised in the overseas colonies, or the then flourishing slave trade under the British flag.

The prohibition of that trade was the first objective of British abolitionists (*see* also ABOLITION MOVEMENT). In this respect the year 1774 was marked by two important events, both brought about by the Quakers: the British Society of Friends decided in its annual convention to expel any Quaker engaged in the slave trade; the Quakers of Pennsylvania created, under the guidance of

James Pemberton and Benjamin Rush, the first antislave-trade society, and soon similar bodies sprang up in other North American colonies. Two years later, in 1776, the Quakers of Pennsylvania took the decision to set free all the slaves they held. In 1783 their English brethren created the first association in England "for the relief and liberation of the Negro slaves in the West Indies, and for the discouragement of the slave trade on the coast of Africa." Among its members were Tom Dillwyn, George Harrison, Samuel Hoare, and others. Thus both in the mother country and in the American colonies the Quakers were the first to give a systematic character to the antislavery movement.

As concerns Great Britain, the next important event in the annals of abolition was the appearance, in 1786, of *Essay on the Slavery and Commerce of the Human Species*, by Thomas Clarkson (*q.v.*). In the process of its publication the author met a number of people sharing his views on the subject, such as Granville Sharp, the man who had brought the *Somersett* test case before the courts, James Ramsay, a clergyman who had himself published an antislavery book, and above all William Wilberforce. This group formed in 1787, together with Josiah Wedgwood, Bennet Langton, Zachary Macaulay, and others, the Society for the Abolition of the Slave Trade, which absorbed the association founded in 1783 by the English Quakers.

Under the influence of the Society and its supporters the Crown appointed in 1788 a committee of the Privy Council to inquire into the slave trade. The next year Wilberforce introduced in the House of Commons a series of resolutions intended to prohibit the slave trade under the British flag and the importation of new slaves into the British West Indies. But, despite his efforts, the first partial result was not achieved until 1806, when Parliament adopted a bill prohibiting British merchants from providing slaves to foreign colonies, and prohibiting also the importation of slaves into the newly acquired British possessions. The next year both houses finally passed a bill introduced by the government of Lord Grenville and Fox prohibiting slave trading by British vessels, as well as the importation of slaves into all British colonies. The traffic continued, however, until the Parliament adopted in 1811 another bill proclaiming slave trading to be a criminal offense. From then on the British navy pursued the now illicit traffic which was ultimately brought under control.

But this victory brought even greater suffering for those slaves who were already in the colonies. As there was no fresh supply, their masters tried to exact more work from them. In 1821, Wilberforce, assisted by Sir Thomas Buxton, undertook his second attack—this time against the institution of slavery itself. In 1823 they, with others, formed a new organization, the British and Foreign Anti-Slavery Society. Their aim was to obtain the immediate liberation of all slaves, in particular in the West Indies. However, the British government announced its plan to achieve the same objective in a more cautious manner: those of the colonies having their own legislative councils were invited to take the necessary gradual measures, although the government warned them that it would intervene directly in case of undue delay. Despite this warning there was practically no progress in the ten following years. Finally in 1833, under the pressure of public opinion, the government decided to take direct action. The Abolition Act of August 28, 1833, provided for a compensation to be paid out of the Treasury to the slaveowners. Furthermore, the slaves were not set free immediately (except when they were under 6 years of age), but had to undergo a period of apprenticeship for seven years. During this period they had to continue to work for their masters three-fourths of the day, in exchange for food and clothing. Later the transitional period was cut by two years and in 1838 all slaves in the British West Indies were set free. Later similar measures were taken in regard to other British possessions as well as in regard to India.

The example of Great Britain was gradually followed by the other European states, and some American ones had already taken action of the same kind. The immediate emancipation of the slaves in the French colonies was decreed by the Provisional Government of 1848. In 1858 it was enacted that every slave belonging to a Portuguese subject should be free in 20 years from that date, a system of tutelage being established in the meantime. This law came into operation on April 29, 1878, and the status of slavery was thenceforth illegal throughout the Portuguese possessions. The Dutch began the emancipation of their slaves in 1863. Several of the Spanish American states, on declaring their independence, had adopted measures for the discontinuance of slavery within their limits. It was abolished by a decree of the Mexican republic on Sept. 15, 1829. The government of Buenos Aires enacted that all children born to slaves after Jan. 31, 1813, should be free; and in Colombia it was provided that those born after July 16, 1821, should be liberated on attaining their eighteenth year.

Three of the most important slave systems still remained in which no steps toward emancipation had been taken—those of the Southern United States, of Cuba, and of Brazil.

2. United States.—The antislavery movement started in the North American colonies long before independence, although slavery was an accepted institution in all of them (for a discussion of slavery in the United States *see* NEGRO, AMERICAN).

In the Declaration of Independence of July 4, 1776, the 13 former colonies stated as a self-evident truth, "that all men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty and the pursuit of Happiness." However, this was a purely doctrinal statement of principles having no immediate practical effect upon the institution of slavery. A denunciation of the slave trade, included in Jefferson's first draft, was deleted by the Continental Congress as being objectionable to some southern and New England delegates.

The question of slavery came up later in connection with the government of territories that did not form part of any one of the states, and the Northwest Ordinance of 1787 expressly prohibited slavery in the territory north of the Ohio River. This measure was in conformity with the then prevailing public opinion: at the Constitutional Convention that same year, Washington, Jefferson, Madison, and Hamilton argued in favour of the abolition of slavery by the Federal Constitution then under discussion. If their views and those of the majority of the delegates did not prevail, this was due to the stubborn opposition of South Carolina and Georgia, which threatened not to join the Union if slavery was to be expressly prohibited. Finally, it was decided to leave the decision whether or not slavery should be abolished to the judg-

ment of each State of the Union. The Constitution provided, however, that Congress might by federal legislation prohibit the slave trade after the expiration of 20 years (which it actually did, as from Jan. 1, 1808).

There is no doubt that in 1787 it was expected that the days of slavery were numbered and that it would come to an end within a few years even in the southern states. But an unforeseeable event—the expansion of the culture of cotton following the introduction of the cotton gin in 1793—brought a complete reversal of the trend in the South. While all northern states enacted legislation abolishing slavery between 1787 and 1804 (although sometimes only progressively), in the South public opinion opposed abolition with ever increasing determination. The main focus of the controversy, however, was not so much the states themselves as the federal territories subject to congressional legislation. The Louisiana Purchase in 1803, the annexation of Texas in 1845, and the treaty of Guadalupe Hidalgo ending the Mexican War in 1848 added vast unorganized territories for the possible expansion of slavery. The Missouri Compromise (*q.v.*) of 1820 acknowledged the southern contention that the Congress could not establish restrictions (*i.e.*, prohibit slavery) for new states that did not apply to all states; the Fugitive Slave Act of 1850 increased the severity of provisions for the return of escaped slaves; and the Kansas-Nebraska Act (*q.v.*) of 1854, repealing the Missouri Compromise, established Kansas and Nebraska as new territories with popular sovereignty, which left the decision on freedom or slavery to the settlers in the territories. An even more far-reaching effect was achieved by the famous 1857 decision of the Supreme Court of the United States in the Dred Scott case, which pronounced the Missouri Compromise unconstitutional and prohibited Congress from legislating on slavery in federal territories. By the same decision the court also rejected the plea of Scott, a slave who had been brought by his master to a "free" state, that he had acquired freedom by this fact.

Despite these controversies it would be a mistake to believe that the antislavery movement had large popular backing even in the northern states. It is true that men like Benjamin Lundy, Elijah P. Lovejoy, Wendell Phillips, Charles Sumner, John Brown, and William Lloyd Garrison (the editor of the *Liberator* and the founder of the New England Antislavery Society; 1832) were denouncing slavery with unrelenting vigour. But they often met not only apathy but outright opposition. Thus Garrison was attacked by a mob in Boston in 1835 and two years later Lovejoy was killed under similar circumstances in Illinois. However, as years passed, more and more northern intellectuals joined the ranks of those who were asking for emancipation. Among them were Emerson, Bryant, Longfellow, Whittier, and Whitman. But probably the greatest contribution in arousing antislavery public opinion was made by Harriet Beecher Stowe's *Uncle Tom's Cabin*, published in 1852 to denounce, in the form of a popular novel, not only slavery itself but also the evils of the Fugitive Slave Act of 1850.

On the other hand, Southern writers defended what they called their "peculiar institution" by all kinds of arguments, drawn not only from economic and social considerations but also from the Scripture. At least in one case arguments in favour of the plantation system and slavery were based on the writings of Karl Marx himself. Most surprising in the attitude of the South is the fact that there were relatively few slaveowners because a slave economy was not possible at all on small holdings. Thus the enormous majority of the white people of the South defended an institution in which they had no direct personal stake.

It has often been said that this defense of slavery would have gradually faded away if sufficient time had been given to southern public opinion to realize that the system had outlived its economic usefulness. Thus it has been indicated that fewer and fewer plantations were making profits, and that most of them were operating on so close a margin that they could barely show a slight profit even in the better years. However, this reasoning did not take into account a number of essential factors. From the economic point of view, whatever the profits, the 4,000,000 slaves who existed in the South in 1860 represented an enormous investment. Since the Revolution the price of slaves had gone constantly up and a slave who would have been worth $300 before the invention of the cotton gin in 1793 brought $1,400 to $2,000 in 1860. Furthermore, southerners believed that the poor state of their economy was not to be blamed on the low return of slave labour and not on the decline of the fertility of the soil, but solely on the selfish policy of the North which had imposed a "tariff of abominations" to protect its industries. But perhaps the most important aspect was of a psychological nature: slavery was for the South an essential element of its way of life, and also an element of "states' rights"—and it was therefore not prepared to give up the institution.

Whatever the case, when the election of Abraham Lincoln to the presidency in 1860 made it clear that northern policies would prevail, the South concluded that it had to leave the Union. It should be remembered that the Civil War was started not for the purpose of abolishing slavery, but with a view to bringing back the rebel states. Nonetheless, once the hostilities began, antislavery became a battle cry for the northern states, as maintaining slavery became a symbol for the Confederacy.

But even under these conditions Lincoln did not at once take measures for the emancipation of slaves. The preliminary emancipation proclamation was issued on Sept. 22, 1862, and the one that followed it on Jan. 1, 1863, applied only to those of the states that were in rebellion against the Union: Arkansas, Texas, Louisiana, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, and Virginia. The state of Tennessee and certain parts of Louisiana and Virginia, as well as the border states still permitting slavery, were exempted from this measure since they were not in rebellion. The proclamation was immediately applied in the regions already occupied by the Northern armies, but these did not include more than 75,000 slaves. Of course, when the Northern armies advanced, its application was extended to the newly occupied territories. But the final liberation came only after the surrender at Appomattox on April 9, 1865. Even then it was questionable whether a presidential proclamation which in its own words was a war measure justified by exceptional circumstances could have affected the legal status of slavery in states whose laws still admitted it. On Jan. 31, 1865, the House of Representatives concurred by a considerable majority in the vote of the Senate favouring the 13th amendment to the Constitution abolishing slavery throughout the Union By Dec. 18, 1865 the amendment had been ratified by three-fourths of the states and was proclaimed in force. Under this amendment "Neither slavery nor involuntary servitude, except as a punishment for crime . . . shall exist within the United States, or any place subject to their jurisdiction" (Sect. 1). Furthermore, the Congress was granted power to enforce this provision by appropriate legislation (Sect. 2). (*See* also ABOLITION MOVEMENT.)

3. France.—In France toward the middle of the 18th century philosophers and writers like Voltaire, Rousseau, Filangieri, and Raynal denounced the evils of slavery and of the slave trade either generally or with special reference to the French colonies in America. Montesquieu, who sojourned in England and was undoubtedly in contact with British abolitionists, wrote: "Slavery is just as much contrary to civil law as it is in opposition to natural law; what kind of civil statute could prevent a slave from escaping?"

The Société des Amis des Noirs (Society of Friends of the Blacks) was established in Paris in 1788. Contrary to the aims of its British counterpart, the French society demanded not only the immediate prohibition of the slave trade but also of slavery itself. The president was Condorcet and among the members were the Duc de la Rochefoucauld, Lafayette, Brissot, Clavière, and the famous Abbé Grégoire. The adoption by the Constituent Assembly, in August 1789, of the Declaration of the Rights of Man seemed to put an end to slavery in the French overseas possessions. However, it was explained, as in the case of the American Declaration of Independence, that the French Declaration was a statement of principles, and that its provisions, to become binding had to be implemented by the adoption of appropriate legislation. Furthermore, the Assembly passed a resolution in March 1790 by which it specifically excluded the colonies from the operation of

the Constitution then in preparation for metropolitan France. This was a bitter disappointment for the coloured population (freedmen of mixed ancestry) of St. Domingue (Haiti), which, although free, did not possess equality of rights with the French planters. Vincent Ogé, a mulatto, in France as head of a delegation representing his people, returned to the colony and organized the first uprising against the French. The revolt was short-lived and Ogé was sentenced to be broken on the wheel. Under the impact of this news, the Assembly adopted a resolution proposed by Abbé Grégoire recognizing the equality of "the people of colour ... born of free parents" and granting them representation in local assemblies on equal terms with the white settlers. But this was not implemented and soon a new uprising shook the French part of St. Domingue. This time many Negroes joined the mulattoes in a common cause. (*See* HAITI.)

In the meantime the Revolution deepened in France and the Convention, which had replaced the Legislative Assembly, adopted a decree on 16 Pluviôse An II (February 4, 1794) abolishing Negro slavery in all French colonies and establishing the equality of all men, without distinction as to colour. This was the first enactment in history prohibiting slavery. The decree, however, could be put into effect only in Guadeloupe and in French Guiana: the island of Martinique had fallen, in the meantime, into the hands of the British, and the colonial assembly of the island of Bourbon (Réunion) refused to apply it. St. Domingue was in a continuous state of turmoil, which finally led to the establishment of Haiti.

After the restoration of the Bourbons in 1814 measures were taken to put an end to the slave trade. But the status of existing slaves remained unaffected until the Revolution of July 1830 and the replacement of Charles X by Louis Philippe. At that time Martinique was shaken by a new Negro revolt, followed by extremely harsh repressive measures by the settlers. Liberal opinion in France was appalled and demanded reforms. Among the most vocal were the famous poet Lamartine, the Duc de Broglie, Alexis de Tocqueville, Isambert, Montalembert, and others. Under their influence a series of measures were taken by the government in 1833, 1836, 1839, 1840, and 1845: manumission was made easier, slaves were placed under the protection of the judiciary, and the separation of slave families was prohibited. But all these measures were only partly applied.

The final action came after the Revolution of February 1848 and the establishment of the Second French Republic, when a commission presided over by the under-secretary for the colonies, Victor Schoelcher, an abolitionist of old standing, prepared a text for the abolition of slavery. This text was implemented between May and August 1848 in all French colonial possessions, as well as in Algeria, where domestic slavery existed.

4. Other European Colonies and Former Colonies.—Most of the Spanish possessions in America abolished slavery when they acquired independence in the first quarter of the 19th century. Thus the government of Buenos Aires enacted a law under which all children born to slaves after January 31, 1813, were declared free. In Colombia children born after July 16, 1821, were to be liberated on attaining their eighteenth year. The Mexican Republic abolished slavery by a decree of September 15, 1829. However, slavery continued to exist in the colonies which remained under Spanish domination—Cuba and Puerto Rico in the Caribbean, and the Philippines in the Pacific. Although certain measures were taken in the course of the 19th century for the gradual abolition of slavery, the most important of which was the so-called Moret Law of 1870, the final emancipation came only after the Spanish-American War of 1898 and the loss of these colonies by Spain.

Portugal had lost its main colony, Brazil, in 1822. However, the Portuguese dynasty continued to rule until 1889 when the last emperor was overthrown and went into exile. Although measures were taken to prevent the slave trade, and as early as 1826 Brazil signed a convention with Britain to that effect, the traffic continued illegally at least until the middle of the 19th century. There, as in the British colonies, the end of the trade brought greater hardship for the existing slaves who were compelled to work longer hours in the mines and on the plantations. However, as already noted, slavery was less cruel in Brazil than in most other countries of the Americas. In 1871 a partial abolition act was passed. Under it the state-owned slaves were liberated at once. The others remained in their servile condition, but the children born to slave mothers after the law was passed were free, except that they had to work for the masters of their mothers for a term of 21 years. A clause provided that a certain sum should be annually set aside from fines to aid each province in emancipating slaves by purchase. It should also be noted that a great number of private slaveowners granted manumission to their slaves and that when the end of slavery was proclaimed by law in 1888, there were not more than 700,000 slaves in the country.

In other Portuguese possessions slavery was abolished in 1858, but the existing slaves remained with their masters for 20 years, a system of supervision and tutelage being instituted for the interim period.

As to the Dutch possessions, the slaves were also liberated, beginning in 1863.

VI. INTERNATIONAL EFFORTS TO SUPPRESS SLAVERY THROUGHOUT THE WORLD

The fight against slavery on an international scale started immediately after the end of the Napoleonic Wars, in 1814, and was still continuing in the second half of the 20th century. It passed through three successive stages: during the first period, from 1814 to 1885, the action was mainly directed against the slave trade; during the second, from 1885 to the end of World War I in 1919, it was, in addition, also directed against slave raiding in Africa; during the third, which covers the periods of the League of Nations and of the United Nations, it was further expanded to cover the Middle East and the Far East, including not only chattel slavery, but also other similar forms of servitude throughout the world.

A. Action Against the Slave Trade

As has been noted, legislative action against slavery in Great Britain started with an attack not against the institution itself, but against the main source feeding it—the slave trade.

Soon after the adoption of the British antislave-trade laws of 1807 and 1811, it became clear that they could be fully effective only if other maritime and colonial countries followed the British example, and international cooperation was established in this field.

1. Search and Seizure on the High Seas.—As the slave trade toward the Western Hemisphere had to use the high seas, the British thought of using, for the purpose of combatting it, two accepted doctrines of international law: the one according to which a pirate vessel is not entitled to the protection of any state; the other according to which warships can arrest, search, and seize any merchantman under any flag guilty of running a blockade or of carrying contraband of war. Clearly if slave trading could be assimilated either to piracy or to blockade running, the British Navy would be entitled to arrest and seize vessels transporting slaves. Such an extension of either of the two doctrines, however, could be achieved only by way of international agreement.

The first treaty of peace signed at Paris on May 30, 1814, included a clause according to which the defeated French undertook to bring slave trading under the French flag to an end. In addition, the French promised to assist the British in their endeavours at the forthcoming Congress of Vienna "to induce all Powers of Christendom to decree the abolition of the slave trade." Talleyrand, however, refused to support Wellington's proposal that international action should take the form of reciprocal recognition of the right to arrest and search vessels suspected of being engaged in the slave trade in the Atlantic north of the equator (the usual route of slave traders).

When the Congress of Vienna convened in November 1814, for a time it still seemed possible to come to an agreement under which the slave trade would have been assimilated to piracy. But here again opposition developed, and finally the Congress adopted a declaration merely enunciating a number of principles to be followed by each of the parties (Austria, France, Great Britain, Prussia, and Russia) for the abolition of the slave trade. The

declaration recognized, however, the need for regard "to the interests, the habits, and even the prejudices" of the subjects of the signatory states, and that "therefore, it was impossible to prejudge the period when this end could be achieved." The declaration envisaged only individual action by the signatories and did not establish a reciprocal right of arrest and search for their warships. The essence of the Declaration of Vienna was again repeated, in somewhat stronger terms, in the declaration of the Congress held at Verona in October 1822.

The British did not give up their efforts. They made first an attempt to claim the right to search foreign slave-trading vessels on the basis of general provisions prohibiting this trade. But the High Court of Admiralty declared that such a right did not exist. Beginning with 1817 they therefore negotiated and signed bilateral treaties with various colonial and maritime powers conceding to the navies of the parties a mutual and reciprocal right of search and seizure over merchantmen engaged in the slave trade in specified waters. Such treaties were concluded with Portugal, Spain, Brazil, and many other countries. In 1841 a treaty of the same type was signed at London between Great Britain, Austria, Prussia, Russia, and France. But France refused to ratify it and another treaty was signed with the French in 1845, establishing only a measure of cooperation between the British and the French navies. Similarly, the United States refused to concede a right of search to the British until the outbreak of the Civil War; a treaty was signed at Washington in 1862.

On the strength of the treaties recognizing a reciprocal right of search and seizure, the Royal Navy undertook energetic action to put an end to the slave trade. British naval squadrons were dispatched for this purpose to the West and East coasts of Africa, where the trade originated, and to waters adjacent to Cuba and Brazil, the main countries of destination of the traffic. The suppression of the trade was not easy because it brought enormous profits to the slavers even if only one voyage out of several was successful. Furthermore, the slave traders often benefited by the complicity of men in power in their respective countries, even when they had declared the traffic illegal and signed treaties with the British for its suppression. Thus the traffic to Brazil was not brought to an end before 1850, and the traffic to Cuba continued until the Treaty of Washington made it possible to search ships under the U.S. flag. The treaty also brought to an end the smuggling of Negro slaves into the southern part of the United States.

There were accusations at times that British naval officers themselves favoured the traffic in order to increase the bounty money they were paid by the Crown for captured and liberated slaves. But even if such abuses occurred, they were undoubtedly contrary not only to the proclaimed but also to the real policy of the British government. There is no better proof for this than its constant insistence to search and seize ships equipped for the transportation of slaves, even when they did not actually have slaves on board. Another accusation leveled against the British in the second half of the 19th century was that, while pursuing the suppression of the African slave trade, they were encouraging a similar traffic in so-called "indentured" labourers. Such labourers were recruited under contract in India, China, certain parts of Australasia and of South America, and transported to British and other European colonial possessions in other parts of the world. It was pointed out that indentured labour was often recruited by unscrupulous means and even outright deceit. Furthermore the employers used all kinds of devices to retain the workers beyond terms fixed in the original contracts, and consequently they either died in the country of employment, or were returned to their native land at an age or in a state of health which could make them only a burden for their communities. (*See* also CONTRACT LABOUR.)

2. Overland Trade in Africa.—Parallel to the action against the maritime slave trade, the British also undertook efforts against the overland traffic in slaves in Africa. Since the exploration of the heart of the Dark Continent started only in the second half of the 19th century, their first efforts were concentrated on the terminal points at which slave caravans reached the shores of the Mediterranean, the Red Sea, the Persian Gulf, and the Indian Ocean. Some of the slaves brought there were sold for local employment, but most were sent farther, usually in small native craft to Turkey, Arabia, Iran, and other eastern countries. Whereas the sea traffic from the West Coast and from Mozambique was mainly confined to adult male slaves to be employed on American plantations, land traffic affected women and young girls as well, whose destinations were the Oriental harems; young boys were also often sold into slavery as eunuchs.

Since the most important slave market was then located in Zanzibar, the ruler of this island was singled out by the British for special attention. The first treaty with him was signed in 1822 by Captain Moresby with a view to limiting the reexportation of slaves. A series of further treaties followed between 1845 and 1876, mainly negotiated by Sir John Kirk, British Consul at Zanzibar. But these agreements were only partially effective and the clandestine traffic in slaves toward exterior markets was brought under control only when the British took the island under their protectorate. More or less similar agreements were also concluded by the British with sheikhdoms on the Persian Gulf, as well as with a number of Somali chieftains. But here too the clandestine traffic continued despite the efforts of the British naval patrols.

B. Action Against Slave Raiding in the Heart of Africa

1. Slave Raiding in Africa.—The exploration of Africa revealed all the horrors of slave raiding and of the traffic in human beings which was going on completely unchecked in a vast territory covering the basins of the Nile and the Congo, and the region of the great African lakes. Dr. Livingstone, Heinrich Barth, Sir Samuel Baker, and many other explorers and missionaries who followed them, described the scenes they had witnessed. This literature had an enormous impact not only on the reading public of England and of the other English-speaking countries, but also in continental Europe. The world learned that hundreds of thousands of men, women, and children were submitted to a systematic manhunt. Only some of them were captured; others were slain or left behind maimed, sick, and deprived of all means of livelihood. Further thousands of the captives perished during the long trek across the African wilderness, or during the sea voyage. In this respect, the surveillance exercised by the British and other navies made matters worse rather than better: because of the risk of capture, the traders packed their crafts to capacity, disregarding not only the comfort of the involuntary passengers but also any security precautions. A further toll was taken by the castration to which boys and young males were subjected and which was performed under unsanitary conditions.

While revealing all these facts, the exploration of Africa, and its aftermath—the occupation, at least nominally, of the newly explored lands by European powers—offered an opportunity to strike at the root of the evil. The new authorities, particularly the British, worked to halt the overland traffic and slave raiding.

An international diplomatic conference at Berlin in 1885, called for the purpose of delimiting the spheres of influence in the Congo basin, presented a first opportunity for the coordination of the action already undertaken by individual European administrations. The General Act of Berlin, which applied only to the so-called "Conventional Basin of the Congo," required all of the powers concerned "to watch over the conservation of the indigenous populations and the amelioration of their moral and material conditions of existence" and "to strive for the suppression of slavery and especially of the Negro slave trade" (art. 6). Under another provision, the contracting parties agreed that the territories "may not serve as a market or way of transit for the trade in slaves of any race whatever" (art. 9).

The next step came in 1889–90 when two further conferences met at Brussels. The Conference of 1889 had only a limited purpose: to recognize Leopold II of Belgium as sovereign of the newly created so-called Congo Free State. On this occasion, Leopold reaffirmed the obligations that he had already assumed as president of the International Association of the Congo, created under his auspices by Stanley, who had signed treaties and agreements with various African chiefs.

2. The General Act of Brussels.—The Second Brussels Conference of 1890 was a far more important event. Its outcome was the General Act of Brussels, which for a quarter of a century constituted the fundamental charter of international efforts to suppress slavery. One of the important facts about the General Act of Brussels was the number of its signatories; in addition to all the major European powers, the United States of America and Turkey, Persia (Iran), and Zanzibar were parties thereto. The participation of the last three countries was particularly significant because at the time they still recognized the institution of slavery. Another characteristic of the General Act was the extent and importance of the territories covered by it: it applied to all possessions of the signatories, although special attention was paid to African regions where slave raiding and slave trading were still flourishing; to the countries of transit; and to those that constituted potential markets for the trade. But perhaps the major feature of the General Act was the broadness of the subjects covered by its provisions. These included recommendations for taking various measures of vigilance in countries of origin and transit, such as the establishment of permanent military posts and the use of patrols for stopping slave raiding and the conveyance of slaves by land. These acts, and some others connected with them, were to be treated as criminal offenses. Other provisions dealt with measures to be taken for the welfare of liberated or fugitive slaves, and their repatriation. The usual provisions concerning the repression of maritime slave trade were inserted; but the mutual right of arrest and search was limited to small native craft (under 500 tons) and in a specified zone along the coast of the Indian Ocean, in the Persian Gulf, and in the Red Sea (by 1890 the traffic toward America had been practically stopped). Under a special provision any slave taking refuge on board a warship of a contracting state was to be set free. The most novel part of the General Act concerned the creation of permanent international institutions for coordinating the fight against the traffic in slaves—the International Maritime Office set up at Zanzibar, and the International Bureau located at Brussels. Laws and regulations enacted for combatting slavery and the slave trade, as well as statistical data concerning this trade, the number of slaves detained and liberated, and similar facts, were to be communicated by the contracting parties, or otherwise collected. The General Act recommended also the creation by the states of various organs and missions for the purpose of protecting liberated or runaway slaves and rehabilitating them through educational and other measures.

Although the Conference of 1890 had been formally convened by the king of the Belgians, it, as well as the General Act it produced, came about largely as a result of the relentless efforts of the international antislavery movement. In particular, one of the members of the Committee of the Anti-Slavery Society of London introduced a motion before the British House of Commons in March 1889, suggesting the convening of such a conference. There is no doubt that the General Act of Brussels played a major role in the years 1890–1914 in the fight against the worst aspects of slavery: the capture of Africans, and their conveyance through the Dark Continent to ports of embarkation and hence by sea to countries where slavery was still legally practised.

3. Extension of Abolition.—Another factor contributing to the reduction of the slave trade during this period was the abolition of the institution of slavery itself in a number of Islamic and Oriental countries, such as Egypt, the Ottoman Empire, Siam (Thailand), and China.

4. New Forms of Forced Labour.—But as against these gains, mention should also be made of factors which led to an increase, if not of slavery proper, of certain other varieties of involuntary servitude. As concerns Africa in particular, in a number of cases European occupation led to the establishment of new forms of forced or compulsory labour, at times even more cruel than those existing under local custom. To quote only one example, in 1897, a missionary leveled grievous accusations against the state of affairs on the rubber plantations in the Congo Free State. In 1905, King Leopold II appointed an international commission which confirmed, at least in part, some of the allegations (*see* BELGIAN CONGO: *The Congo Free State*). As a result, under various pressures, the king transferred the territory to Belgium as a colony. This made possible the control of the colonial administration by the Brussels Parliament, and conditions improved notably in the ensuing years. The latter arrangement remained in force until June 30, 1960, when the (Democratic) Republic of the Congo came into being as an independent state.

C. Direct Attack Upon Slavery and Other Forms of Servitude

The outbreak of World War I in 1914 brought to a standstill the work of the international organs set up under the General Act of Brussels, the International Maritime Office at Zanzibar and the International Bureau at Brussels. At the close of the war the principal Allied powers signed a new convention at Saint-Germain-en-Laye on September 10, 1919, intended to release the signatories (Belgium, the British Empire, France, Italy, Japan, Portugal, and the United States) from their obligations under the Brussels Act, and substituting a declaration that they would "endeavour to secure the complete suppression of slavery in all its forms and of the slave-trade by land and sea." It remained at least doubtful whether or not these or the other signatories of the Brussels Act of 1890 were still bound by its provisions.

1. The League of Nations.—The Saint-Germain Convention coincided with the creation of the League of Nations. The international work carried on by the League for the suppression of slavery may be considered under the following headings: (a) action concerning mandated territories; (b) action in respect to certain other countries; and (c) general activities aimed at combatting the slave trade, and slavery and similar institutions and practices, including enforced prostitution.

Former Ottoman territories and German colonies were placed under the mandate (*q.v.*) system. When the instruments for their administration were drawn up, provisions were inserted for the suppression of the slave trade and for the prohibition of forced labour, except for essential public works and in return for adequate remuneration. Class B mandates, which applied to most of the former German territories in Africa, also included undertakings on the part of the mandatory powers to provide for the eventual emancipation of all slaves and for as speedy an elimination of domestic and other slavery as social conditions would allow. The mandatory powers had to present annual reports on their administration, including information on such problems as slavery, the slave trade, forced labour and other forms of servitude, and on measures taken for their suppression. These reports were examined first by the Permanent Mandates Commission, composed of experts, and thereafter by the Council of the League of Nations, which made various recommendations from time to time.

The work of the League in regard to other countries concerned, in the most notorious instances, Ethiopia and Liberia. When Ethiopia applied for admission to the League, some delegations opposed this application on the ground that slavery existed in that country. The Ethiopian government gave a pledge, accepted by the League's Council, to abolish slavery within a definite time and to at once take preliminary steps to that end. Despite the Italian-Ethiopian War of 1934–36, and the temporary loss of independence, Ethiopia lived up to this undertaking and slavery was abolished in 1942, once the country recovered its independence. In the case of Liberia, following certain allegations, an international commission was sent to that country in 1930. The commission stated in its report that classic slavery no longer existed in Liberia, although intertribal slavery and some other forms of servitude, including forced labour, were found to be serious problems. The commission made recommendations including action by the government of Liberia and financial and technical assistance by the League. The Liberian government accepted these recommendations in principle, and availed itself of the help offered. The League also made recommendations to countries having large Muslim populations in order to check more carefully the movement of pilgrims to the Hejaz. It had received information that pilgrims sometimes sold servants and even their own children into slavery in the country of their destination. Incidents of this kind have been reported as late as in the 1950s, in particular in a report

presented in 1955 by M Emmanuel La Gravière to the Assembly of the French Union, recorded in Document No. 75 of the Assembly of the French Union, Session of 1955–56.

The League of Nations took up the general problem of slavery in 1920. In 1924 the League set up a Temporary Slavery Commission of experts to collect information on slavery proper (including so-called domestic slavery), slave raiding and the slave trade, and also on such other institutions and practices as serfdom, purchase of girls as brides, sham adoption of children to exploit their work, various forms of indenture, or reducing to servitude, of persons for debt or for other reasons, and systems of compulsory labour, both public and private. The commission recommended the conclusion of an international convention covering all these matters.

However, when the League of Nations Assembly adopted the International Slavery Convention in 1926, it created ambiguity as to its scope. It decided not to include the subject of forced or compulsory labour, which it referred for further study and action to the International Labour Organization (*q.v.*). The other institutions and practices described by the Temporary Slavery Commission were all, with the exception of serfdom, to be brought under the operation of the Convention. At least this was stated in the report of the Assembly's committee which prepared the final text. But the Convention itself included a provision defining slavery as "the status or condition of a person over whom any or all the powers attaching to the right of ownership are exercised." When the Convention came into force, several of the contracting states considered, on the basis of this text, that it concerned only "chattel" slavery, and that they were not bound by it in regard to other institutions which did not imply the right of ownership over a person.

The substantive provisions of the Slavery Convention of 1926 did constitute real progress as compared with those of the General Act of Brussels—and fell short of them in many cases. For example, the parties undertook to suppress the slave trade in all territories under their control, but promised only "to bring about progressively and as soon as possible the abolition of slavery in all its forms." Even the traditional provisions of former treaties concerning a mutual and reciprocal right of arrest and search of vessels suspected of slave trading were not inserted in the new convention, although it was envisaged that such provisions could find their place in another international instrument. Nor did the Convention establish permanent international organs on the lines of those that had been set up under the Brussels Act for the implementation of its provisions by concerted action; it provided only for exchange of information, mainly of a legal character.

The absence of a permanent international organ dealing with slavery was felt as the major shortcoming of the 1926 Convention and the British government took the initiative in filling this gap. On its proposal, the Assembly in 1932 decided on the establishment of the Advisory Committee of Experts on Slavery as a permanent organ of the League. Experience had shown that states were often reluctant to supply information on objectionable practices within their own borders; the Advisory Committee therefore was authorized to rely also on the special knowledge of the various aspects of slavery and of the slave trade of its own members, who were independent from governments. Furthermore, the Committee was to proceed in a confidential manner, and even its reports could be published only to the extent decided by the Council of the League. This assured considerable freedom in its debates, as well as the possibility of taking discreet diplomatic action, often more conducive to results than direct and open pressures on governments. The Advisory Committee worked from 1934 until 1938; only the events that led ultimately to World War II prevented it from holding further sessions. In its last report (April 1938) the Advisory Committee pointed out that there had been considerable improvement in the main problems related to slavery. In this connection, it should be indicated that, in addition to what has already been said about the League's action in Ethiopia and Liberia, during the period between the two World Wars the legal status of slavery was abolished in Afghanistan (1923), Iraq (1924), Nepal (1926), Transjordan, under British Mandate, and Iran (1929), and Bahrain (1937).

2. The United Nations and Human Rights.—When after the conclusion of the Second World War the United Nations organization replaced the League the question of combatting slavery in its different forms came once again to the fore. The General Assembly, at its third session (1948), adopted the Universal Declaration of Human Rights which in article 4 states that "1. No one shall be held in slavery; slavery and the slave trade shall be prohibited in all its forms; 2. No one shall be held in servitude."

Following the fourth session of the General Assembly, in 1949, an Ad Hoc Committee of four members was set up "to survey the field of slavery and other institutions or customs resembling slavery." This body, in 1951, presented a report to the Economic and Social Council outlining a program for action. The basic ideas were that the League of Nations' 1926 Slavery Convention, binding forty-five states, should be maintained in operation and brought into the framework of the UN, which, however, should also prepare a new international instrument to make sure that not only chattel slavery but also other institutions and practices already studied by the League of Nations, and servitude of women resulting from marriage practices, should be brought to an end. In addition, mindful of another experience of the former League, the Ad Hoc Committee recommended the creation of a Standing Committee of Experts to supervise the application of both the old and the new conventions.

3. Continued Existence of Slavery.—The UN implemented the first recommendation in 1953 by executing a protocol transferring to its Secretary-General the powers and duties of the League's Secretariat in regard to the 1926 Slavery Convention. The conclusion of a supplementary convention was implemented in 1956, after a number of further studies, summarized in a report presented in 1955 by Hans Engen of Norway. In his introduction he pointed out that he endeavoured "to extract . . . only those statements which, in his view, would assist the [Economic and Social] Council in surveying the extent to which slavery, and practices resembling slavery, exist in the world today." He stated, however, that the documentation was in some respects incomplete and unverified. It must also be added that a number of governments concerned either denied the information in the report, or stated that it was inaccurate or out of date, or indicated measures had been taken to combat the objectionable practices reported. The material in the report on the continued existence of slavery (including "domestic slavery") and the slave trade concerned a number of countries in the Arabian Peninsula. Mention was also made of a few countries in Southeastern Asia, Africa, and South America. The material on serfdom concerned mainly countries in Asia, although certain regions in Africa and one country in Central America were also mentioned. The material related to "traditional forms of unpaid or underpaid personal services exacted by landowners and other employers of labour, or their agents" concerned a number of South and Central American countries, certain regions in Africa, in East and Southeast Asia, and in the north of the Arabian Peninsula. The material related to debt bondage, including pledging and pawning of third persons as security for debt, concerned a number of countries in East and Southeast Asia, in the north of the Arabian Peninsula, in various parts of Africa, and Latin America. The material related to the exploitation of children, notably under the guise of adoption, concerned various countries of East and Southeast Asia, South America, and one country in Africa. The material related to the "purchase" of wives and the "inheritance" of widows concerned mainly territories in Africa and in Northern Australasia, as well as one country in South America and a few in Asia.

4. Attack on Other Forms of Servitude.—The Supplementary Convention on the Abolition of Slavery, the Slave Trade, and Institutions and Practices similar to Slavery, based on a draft submitted in 1954 by the United Kingdom, was approved by a diplomatic conference at Geneva in 1956. The major feature of the Supplementary Convention lay in the fact that, although it maintained the 1926 definition of slavery, this definition had been supplemented by a description of the various institutions and practices similar to slavery, referred to above, in respect to which the signatory states agreed to "take all practicable and necessary legis-

lative and other measures to bring about progressively and as soon as possible [their] complete abolition or abandonment" (art. 1). Further, with a view to bringing to an end marriage institutions and practices leading to involuntary servitude for women, the states undertook to prescribe minimum ages of marriage and to encourage the use of facilities assuring the free consent of the parties to marry. (In 1962 the General Assembly adopted a convention drafted by the Commission on the Status of Women, calling on the states to assure that all marriages meet the requirements of minimum age, consent of both parties, and official registration.) The Convention of 1956 prohibited the mutilation, branding, or other marking of slaves and other persons of servile status. It also made punishable acts which might lead to the enslavement of a person, or to placing him into one of the servile conditions mentioned above. In some other respects the Supplementary Convention of 1956 was less satisfactory. In particular, once again governments were unable to agree on a clause authorizing their warships to exercise a reciprocal and mutual right of search on vessels suspected of slave trading. But under one provision, any slave taking refuge on board of any vessel of a state party to the Convention becomes *ipso facto* free. The Convention also established cooperation between party states and prescribed communication by them of certain information to each other and to the Secretary-General for submission to the Economic and Social Council "as part of documentation [in] view of making further recommendations for the abolition of slavery, the slave trade or the institutions and practices which are the subject of this Convention."

SLAVIC (SLAVONIC) **LANGUAGES.** The Slavic languages represent a western branch of the eastern, or satem, division of Indo-European (*q.v.*) and are closely connected with the Baltic languages, which embrace Lithuanian, Latvian, and the now extinct Old Prussian.

Classification.—Slavic languages are spoken in parts of East Germany, in Poland, Czechoslovakia, Yugoslavia, Bulgaria, and in most of the European part and large areas in the Asiatic part of the U.S.S.R. There are 13 living Slavic languages, classified in three groups. (1) Russian (more specifically, Great Russian), Ukrainian (formerly called Little Russian or Ruthenian), and Belorussian (or White Russian) comprise the East Slavic group (2) Polish, Slovak, Czech, and the High and Low Sorbian (also called Lusatian or Wendish) of East Germany form the Western group. (3) Slovene, Serbo-Croatian, Macedonian, Bulgarian, and Church Slavonic make up the Southern group. Church Slavonic is the liturgical language for all Orthodox and some Catholic Slavs, and its use is by no means confined to the South Slavic area. The two Sorbian languages were guaranteed a place in schools and public life by East German laws promulgated in 1948 and 1950. The other ten are official state languages in their respective areas.

Two additional languages may be noted, Polabian and Pomeranian. The former, once widely spread in the Elbe basin, became extinct in the 18th century. The latter is the conventional name for dialects once spoken along the Baltic, known from two remnants, Slovincian and Kashubian, which survived into the 20th century.

In spoken Slavic dialects, there are scarcely any true linguistic frontiers, for transitional dialects connect all types, excepting, of course, in the area where the South Slavs are separated from the others by non-Slavic Austrians, Hungarians, and Rumanians. Almost any two intelligent Slavs can manage fairly quickly to establish elementary communication on a simple conversational level, for the languages have preserved a remarkable degree of uniformity in over-all grammatical pattern and in the vocabulary of everyday life. However, the myriad differences in the details of phonetics, grammar, and above all of vocabulary cause misunderstandings even in the simplest of conversations, and the difficulties increase in the language of journalism, of belles-lettres, and especially in technological treatises, which tend to use newly created terminology. For a Slav to master effectively a second Slavic language demands time and work.

History.—For at least a millennium before the 3rd century A.D. the Slavs lived north of the Carpathians. (*See* further SLAVS.) Scholars have not been able to reconcile archaeological and linguistic evidence to arrive at a wholly satisfactory delimitation of the area, but they generally agree that its core extended from the Vistula to the Dnieper (Dnepr). Linguistic affinities indicate that the western neighbours of the Slavs were very likely first Illyrians, later perhaps Celts, and then Teutons. In the southeast there was apparently contact with Iranian and various Altaic peoples. In the northeast were Finno-Ugric tribes, and in the north the Balts. In the first centuries A.D. the Slavs began to expand rapidly, first to the west and east, then southward through and around the Carpathians, appearing in the 6th century as a serious threat to the Roman Empire all along the Danube. By the 9th century they occupied Europe east of a line running roughly Kiel-Brunswick-Magdeburg-Bamberg-Passau-Trieste, including all of the Balkan mainland except for parts of the littoral in Dalmatia and Greece. During the last millennium they have either retreated before or been absorbed by Germans in the west, Greeks and Albanians in the south, and Hungarians and Rumanians in the Danube basin. Only in the east was Slavic expansion a continuous process, which carried the Russians to the Pacific in the 18th century.

A long period, fully three millennia, separates recorded Slavic from any conceivable type of Indo-European from which Indic, Greek, and Slavic could all have sprung. The phonetic and morphological affinities now observable between Baltic and Slavic demonstrate at least a long period of contiguity between Slavs and Balts, and perhaps, as some hold, an ancient Balto-Slavic group. In any case, the Slavic of the 9th century appears still to have been a single language. It was of course divided, like all languages, into regional dialects, but the points of divergence were relatively few in number and quite insignificant in quality.

The 8th–11th centuries brought enormous changes to the Slavs. Slavic states arose and clashed with one another and with their non-Slavic neighbours. Social and economic conditions were radically transformed. In language, too, change was relatively rapid; and by the 10th century the western and southern dialects had split into something like the present linguistic divisions, although in the east a greater uniformity prevailed.

No credible evidence attests to Slavic writing before the 860s when a mission was sent from Byzantium in answer to the request of Prince Rostislav of Moravia for teachers "in our own language." The mission was

led by a brilliant scholar and diplomat, Constantine (later known as St. Cyril, d. 869), and his brother Methodius (d. 885) of Thessalonica, a Greek city entirely surrounded by Slavs. (*See* CYRIL AND METHODIUS, SAINTS.) They created a new alphabet, the Glagolitic, and began to translate church books. Within two decades the Bible and many homiletic and liturgical texts had been translated, and some original works, including poetry, had been written in the new literary language. This language is called Old Church Slavonic (O.Ch.S.) because its local Macedono-Bulgarian origin is of less importance than its use as a literary language in the west (Moravia, Bohemia, Pannonia), the south (Bulgaria, Macedonia), and the east (Russia) during the next two centuries. In time it was modified locally, and the Church Slavonic in use today shows clearly the hand of Russian editors.

CYRILLIC ALPHABET

In the West Slavic area O.Ch.S. was suppressed during the 11th century, but its influence is to be seen in the vernacular literature which sprang up in Bohemia in the 13th century and flourished in the 14th–15th centuries. Czech culture was exported to Poland at this time, and the Poles quickly developed their own standard language and produced superior literature in the 16th and 17th centuries. The Slovaks, if writing Slavic at all, used Czech until the national revival at the beginning of the 19th century. Sorbian texts began with Protestant translations in the 16th century.

In the south, Church Slavonic, in its progressively modified local forms, remained the exclusive written language for the Orthodox Serbs, Macedonians, and Bulgars, and for those Croatian Catholics who clung to the Slavonic rite. It was the Renaissance which gave the impulse to vernacular literature in Croatia in the late 15th century, and the Reformation which produced the first works in Slovene in the 16th century (except for fragmentary texts from the 11th). The Serbs discarded Church Slavonic in favour of the vernacular early in the 19th century, and by 1850 a common Serbo-Croatian literary language had been elaborated. The development of modern standard Bulgarian had its roots in the 18th but progressed little before the mid-19th century. Macedonian is the youngest Slavonic literary language, and can hardly claim to any history before 1944, when it was proclaimed the official language of the new Republic of Macedonia.

In the east, Church Slavonic continued in use well into the 18th century, although strongly vernacularized modifications were used for business documents and occasionally other writing. In Russia, the modern literary language grew out of a compromise style which utilized Church Slavonic elements to enrich the native Great Russian vernacular. The Ukrainians, on the contrary, rejected Church Slavonic in principle and based their writings chiefly on the spoken dialects. The first modern works appeared at the very end of the 18th century, but the real development of the contemporary Ukrainian literary language dates from the 1840s. The Belorussians had used their own distinctively modified type of Church Slavonic in the 16th century, but literature in the vernacular came only three centuries later. It is difficult to speak of a Belorussian literary language before the 20th century. Its most significant growth came about after it achieved official status in 1918.

Alphabet.—Slavic languages in the east and southeast are written in slightly variant forms of the so-called Cyrillic alphabet (*see* table), which seems to have been devised in Bulgaria at the end of the 9th century, and which soon displaced Constantine's Glagolitic. In the west, Roman Catholic Slavs use the Roman alphabet, mostly with the diacritics introduced by John Huss. Serbo-Croatian is written in Cyrillic by Serbs and Montenegrins and in Roman by Croats.

Vocabulary.—Much of the Slavic lexicon is Indo-European in origin ("mother, house, be"), a significant portion may be called Balto-Slavic ("head, hand"), and many words seem to be purely Slavic ("human, dog"). Ancient borrowings from Iranian include important words of spiritual culture ("god, sacrifice"), and a somewhat later stratum from Germanic pertains to material culture ("coin, buy"). The vocabulary of the individual languages reflects more recent local influences, the most important being German in the west and Turkish in the Balkans. Loan translations from Greek in the east and Latin in the west have served as patterns for creating new terminology with Slavic elements in many languages. Inter-Slavic borrowings are manifold and often difficult to trace.

Morphology.—Common Slavic (C.S.) retained the Indo-European case system almost intact, the only innovation being that the ablative merged with the genitive. Still discernible in late C.S. was the older system of paradigms based on purely

formal distinctions of stem and suffix-type: *o*- and *jo*-stems, *a*- and *ja*-stems, *u*-stems, *i*-stems, and, in restricted numbers, *ū*-stems and several kinds of consonant-stems. As early as O.Ch.S., however, a strong tendency prevailed to reorganize the system on the basis of gender. Thus *o*-, *jo*-, and *u*-stems were united in a masculine-neuter paradigm which has slightly variant suffixes according to whether the stem ends in a palatal ("soft") or nonpalatal ("hard") consonant, the usual feminine declension includes *a*- and *ja*-stems ("hard" and "soft"), and the *i*-stems are predominantly feminine. This principle of classification triumphed almost completely in the modern languages, except for Bulgarian and Macedonian, where the only remnant of declension is in vestiges of a general objective case. The West Slavic languages kept hard and soft variants of the masculine-neuter and the feminine *a*-declension, but in the Eastern and Southern groups there are only three paradigms for all but irregular nouns. The vocative disappeared completely in Russian and is preserved only with a limited number of nouns in Slovak, Slovene, and Low Sorbian. Broadly speaking, the force of the cases is weaker in the West, while in Russian some scholars see a strengthening and extension of the case system in the relatively new forms which have specifically partitive or locative functions, over against the forms which are generally genitive or prepositional.

The C.S. verb lost the voices and moods of Indo-European, retaining special forms for two past tenses (the imperfect and aorist), the present, imperatives (derived from the old optative), and five participles, two passive and three active. The active resultative *l*-participle was used with auxiliaries to form a series of periphrastic perfects. Constructions with the reflexive pronoun, and to a lesser degree with passive participles, render the passive and middle voices of classical languages.

The most significant innovation was the development of *aspect*, which remains the pivotal feature of all Slavic verb systems. Every verb is either of perfective aspect, denoting an action viewed in its entirety, or of imperfective aspect, denoting an action not necessarily so viewed. In principle, every verbal idea is represented by a pair of verbs, one for each aspect. Most modern languages have lost aorist and imperfect, using the old perfect instead. The two are, however, completely living forms in eastern Serbo-Croatian, Macedonian, and Bulgarian, where the perfect has come to signify a past action not witnessed by the speaker.

Phonology.—As a satem language, Slavic has *s* and *z* for the Indo-European palatal stops $\hat{k}$ and $\hat{g}$. In a development paralleled by, but not identical with, Baltic and Iranian, Slavic changed *s* to *x* (*kh*) after *i*, *u*, *r*, and *k*. As in Baltic and Germanic, *o* and *a* coincided in Slavic, the short vowel eventually resulting in *o* and the long in *a*. With Baltic, Slavic completely lost aspiration and maintained a sharp distinction between voiced and voiceless consonants. Specifically Slavic features are: an insistence on the distinction between front and back vowels which led to mutual adaptations between vowels and adjacent consonants and resulted eventually in a distinction between soft and hard syllables; the change of short *i* and *u* to reduced, ultrashort vowels called *jers;* the gradual elimination of closed syllables by dropping final consonants or simplifying clusters, by reducing diphthongs ending in *i*, *u*, or nasal, and by various dialectal changes in diphthongs ending in *l* or *r;* the replacement of quantitative vocalic distinctions by qualitative ones, and the subsequent development of a new quantitative system with rising or falling intonation possible on short as well as long vowels.

The table gives examples of some common words to show typical phonological divergences among the Slavic languages, while the relatively modern equivalents for "industrial worker" and "button" give a hint as to differences in roots and in word-formation. Some details are obscured by the different types of orthography current. Particularly significant for the classification of the languages is the development of *tj*, *dj*, *ě*, *ǫ*, *ę*, *ĭ*, and *ŭ*.

Bibliography.—R. Jakobson, *Slavic Languages* (1955), includes a concise account of historical phonology and grammar and carefully selected bibliography. R. G. de Bray, *Guide to the Slavonic Languages* (1951), furnishes practical information. K. Horálek, *Úvod do studia slovanských jazyků*, 2nd ed. (1962), in Czech, is the only detailed introduction. A. Meillet, *Le Slave commun* (1934), is the best description of Common Slavic.

(H. G. L.)

SLAVOPHILS, 19th-century Russian intellectuals who extolled the superiority of the typically Slav, or Russian, way of life. A group in the sense of intellectual affinity rather than organization, they opposed the modernization of Russia in the Western image as advocated by the so-called Westernizers. The Slavophils argued that Russia was basically different from the West in national character, that its foundations were unique and superior, and that some day Russia would emerge as the saviour of the West.

Slavophil ideas may be traced back to medieval times and to the doctrine that Moscow was the Third Rome, the eternal capital of the only true Christian ruler. They were rooted in the criticism of the West that had mounted concurrently with Peter the Great's efforts at westernization; in the new nationalism exemplified by A. S. Shishkov (*q.v.*) and fanned by Napoleon's invasion of Russia in 1812; in the writings in praise of autocracy by such historians as N. M. Karamzin (*q.v.*); and in the deliberations of the Lovers of Wisdom, or Lyubomudry, a circle of Russian devotees of the German idealist philosopher F. W. von Schelling (*q.v.*). The Slavophil movement took shape in the 1830s and early '40s, was at its height between 1845 and 1860, and faded toward the end of the 19th century.

The Slavophils were members of the gentry, a small circle of friends and relatives. Their antagonism toward the West was not the product of ignorance. They were well educated, both in Russia and abroad, were widely read in Western thought, and were influenced by many foreign authors such as Schelling and Hegel (*q.v.*). Philosophers by avocation, they tended to be less systematic and scholarly than haphazard and polemic in their writings.

The dominant figure of the Slavophil movement was A. S. Khomyakov (*q.v.*), a man of remarkable versatility, whose many writings ranged from Oriental philosophy to technology. His lyrical dramas *Ermak* (published 1832) and *The False Dimitri* (1833) were expressions of his belief in Russia's great mission and role as leader of all Slavs—a doctrine which he propagated repeatedly in his other writings and in debate with fellow intellectuals. Close to Khomyakov in importance and ideology, though more romantic, lonely, and depressed in personal makeup was I. V. Kireevski (*q.v.*), "the philosopher of Slavophilism," who formulated a new Slavophil philosophy in his *Answer to Khomyakov* and *On the Necessity and the Possibility of New Principles in Philosophy*. His brother Petr enhanced the movement by contributing to the study of Russian folklore through a large collection of folk songs. Two other brothers, the Aksakovs, were in the forefront of the Slavophils (*see* Aksakov): Konstantin, the historian of Slavophilism, was the most extreme member of the movement, dogmatically opposed to anything foreign, be it language, thought, or dress; and Ivan used his post as secretary and then as chairman of the Moscow Slavonic Benevolent Committee to make himself the foremost advocate of Pan-Slavism. Ivan Aksakov was also a leading figure in the Society of the Friends of Russian Letters and in the Orthodox Missionary Society; but he is most noteworthy as the popularizer of Slavophilism, since his writings reached more readers than the works of the other Slavophils. The most important Slavophil in terms of public position was Yuri Fedorovich Samarin (1819–76), a prominent theoretician. More liberal than the other Slavophils and a leading figure in the movement for the emancipation of the serfs, Samarin in his booklet *Revolutionary Conservatism* opposed constitutionalism as giving power to the landed gentry at the expense of the people. He was a readable, prolific, and versatile writer, propagating the Slavophil ideology in every field.

The Slavophil ideology embraced different, at times contradictory, ideas. To speak generally, the Slavophils subscribed to the following views:

1. Man is by nature religious. The religious element in him is more significant than his national or racial composition. Faith is more important than fatherland, and the church should be free from state interference.

7. The Orthodox Church is the essence of Slavdom. It is the only true church. The Russians are the only true Christians—simple, frugal, humble, and human (indeed, Humanity itself), with a high mission.
3. Russian life finds its fullest expression in the Christian brotherly love of the peasant communes, which encompass the majority of the Russian population. Russia is the mass of the people on the land, a classless society.
4. Land is the property of the communes, not (as in Roman law) of individuals. Private ownership of land as well as serfdom is wrong.
5. The commune is the natural level of administration in economic, religious, and other areas. Central government is a necessary evil. The tsar performs a useful function, but the ruling class is antinational.
6. The Russian people is by nature nonpolitical. Participation in government would corrupt it. Hence autocracy, with its lack of popular participation, is desirable. The role of the tsar is not one of glory, however, but one of sacrifice and martyrdom. He must not infringe the spiritual freedom of the people.
7. The history of Russia is one of organic growth, free of internal strife and divisions. Russia is an organic state, built on the glorious past of the Slavs and held together by Orthodoxy, in contrast with the West, where one-sided rationalism has led to political and social upheaval.
8. Russia is unique, different from and in contradiction to the West.
9. The Russian spirit and soul are expressed in the Russian language, which is closer than other tongues to the original language of mankind.

The relationship of Russia to the West has been a perennial problem in Russian history. The Westernizers, like the Slavophils, recognized the differences between Russia and the West. Unlike the Slavophils, however, they advocated the transformation of Russian society in the Western image. The Slavophils admitted the advantages of Western technology, but inveighed against the materialism of Western life. Influenced by Hegel, they viewed the relationship of Russia and the West in terms of dialectical opposites, though they expected the struggle to result in the dominance of Russia (the thesis) over the West (the antithesis) rather than in the evolution of a new culture (the synthesis). They had a "we-and-they" approach, praising the Russian and condemning the foreign. Deeply steeped in Western learning, notably in German idealism and in the Romantic idea of the nation and of the national mission, the Slavophils yet hated the West and were convinced that the feeling was mutual.

The Slavophils exaggerated the historical importance of the Slavs. Khomyakov, for example, regarded the Slavs as the original settlers of the European continent. He labeled the Angles, the Trojans, the Huns, and the Bulgars as Slavs and adopted Siegfried, Parsifal, Thor, Apollo, and Venus as Slavic figures. He asserted that the Slavs, with their Orthodox Christianity and their agricultural communes, had lived in an idyllic state of harmony until the reforms of Peter the Great had opened the floodgates for alien ideas—legalism, materialism, rationalism, and compulsion—fostering class division and conflict. Thus the Slavophils were able to discern enemies in St. Petersburg as well as abroad. The conservative bureaucrats at the Russian court were to them as alien and dangerous as the Westernizers, liberals, and radicals.

Convinced of the ultimate victory of truth, the Slavophils were opposed to censorship, whether of themselves or their rivals (the social scientists and unreligious philosophers). Their advocacy of freedom of conscience and speech and their attacks on the "anti-Russian" government invited repression. But the seeds of failure lay within Slavophilism itself. Slavic nationalism and Christian universalism were irreconcilable, the former ultimately emerging victorious. The Slavophil view of Russia as above social struggle proved false, the Slavophils having mistaken passivity for harmony. The elevation of the commune above the individual was as vain a prospect for freedom as the belief that the state would eventually wither away. Nevertheless the significance of the Slavophils was far from ephemeral. Slavophil themes pervade the writings of F. M. Dostoevski (*q.v.*); and elements of Slavophil thought passed into the mental makeup of Russians of the 20th century. History has proved the Slavophils wrong in many of their interpretations and predictions, but their emphasis on the fundamental problems of human faith, motivation, and life, and their attempt to find the basis for a true Christian society remain of value.

SLAVS, the most numerous ethnic and linguistic body in Europe, with a considerable extension in northern Asia. Linguistically, they belong to the group known as Indo-European. (For their languages, *see* SLAVIC LANGUAGES and separate articles on the individual tongues.) The main block territory inhabited by the Slavic peoples includes almost all eastern Europe between the White, the Baltic, the Black, and the Caspian seas; westward it extends to the Oder (Odra) and the Lusatian Neisse (Nysa Łużycka) rivers, to the Erzgebirge (Krušne Hory), and to the Böhmer Wald (Český Les); and eastward it stretches across Siberia as far as the Pacific Ocean. In the Balkans there is the further Slavic area represented by Yugoslavia and Bulgaria, but this is separated from the main block by non-Slavic Hungary and Rumania.

The number of Slavs in eastern Europe or in northern Asia was estimated in the early 1960s at 226,600,000. They may be subdivided into East Slavs (Russians, Ukrainians, and Belorussians), 161,000,000; West Slavs (Poles, Czechs, Slovaks, and Lusatians), 43,700,000; and South Slavs (Serbs, Croats, Slovenes, Macedonians, Montenegrins, and Bulgars), 21,900,000. In addition there were about 10,000,000 people of Slavonic origin in the Americas, in western Europe, and in Australia.

The Slavs (Russ. *Slavyane*, Pol. *Słowianie*) were known in ancient times under two names: one which they themselves used and from which the English form Slav is derived; and another which non-Slav peoples used and from which the term Wends comes. The former, traceable to the 4th–5th century A.D., is of controversial etymology: some Slavists consider that it describes people of the same ethnic origin, others that it was applied to peoples dwelling in the proximity of rivers and lakes. A form of the name Wends was used by the Celts of the 1st century B.C. mainly to designate the West Slavs living east of the Elbe River; Pliny the Elder (1st century A.D.) recorded it as Venedi; later the Goths called the Slavs Wenden or Winden; and even today the Finns and the Estonians call Russia Venäjä. (GE. L.)

PHYSICAL ANTHROPOLOGY

Territorial expansion (*see* below, *Slav History and Culture: The Great Migrations*) has produced a considerable differentiation among the Slavs from the anthropological point of view. The following groups may be distinguished:

1. Nordic, with fair, almost pink, complexion, generally blue eyes and blond hair, long head, narrow and straight nose, tall stature, and slender body.
2. Laponoid (or Alpine), with dark eyes, dark or black hair, sallow complexion, round head, large face, broad nose, and short and thick-set body.
3. Mediterranean, with darkish eyes and hair, sallow complexion, rather long head and oval face, narrow and straight or aquiline nose, and small but well-proportioned physique.
4. Armenoid, with dark eyes and black hair, pale complexion, short head with a flattened back to the cranium and a face narrowing toward the chin, strong hooked nose, and tall stature.
5. Paleo-European, with fair eyes, hair, and skin, elongated head, large face and nose, heavy physique, and tall stature.

The Nordic type prevails numerically over the Laponoid, and Mediterranean admixtures are commoner than Armenoid. This quantification is valid in general for the northern part of the West Slavonic territory and for most of the East. Among the Ukrainians, however, Armenoid admixtures are commoner than Mediterranean. Among the southeastern Russians the Nordic majority is mixed more with the Mediterranean than with the Laponoid type, an obvious consequence of the absorption of the Iranian steppe peoples, descending from the Scythians, Sarmatians, and Alans.

In the Sudetic-Carpathian area, the anthropological structure is different. In Upper Lusatia, in southern Poland, and among the

Czechs and Slovaks, the Laponoid element is stronger than the Nordic and the Armenoid admixture greater than the Mediterranean. This is to be explained by the relatively late slavicization of this area. North and northeast of the Carpathians, save in Polesie, the presence of the Laponoid element is rather exceptional.

The predominance of the Mediterranean type is the main anthropological characteristic of the Bulgars as well as of the populations (only partly Slavic) living northwest of the Black Sea. The Macedonians, however, although linguistically akin to the Bulgars, are anthropologically different from them. The reason is that the Bulgars arrived in a territory with an archaic Mediterranean population, while in the western part of the Balkan Peninsula this stock had been overlaid by an Armenoid one, resulting from an expansion of Asianic (Anatolian) tribes. The occupation by the Serbo-Croats of a section of the latter area resulted in a very considerable absorption of the Armenoid element. The Slovenes, geographically neighbours and linguistically akin to the Serbo-Croats, are very different from them anthropologically, the Nordic element being predominant among them.

The Paleo-European type, a considerable admixture among the European population in the Mesolithic Age, is only slightly represented among the Slavs. It is most noticeable where archaic Finno-Ugric indigenous populations have been russified.

This account of the present anthropological character of the Slavs reflects their ancient contacts with the Germanic tribes as well as the consequences of their expansion eastward and southward. Very little is known about their anthropological structure before their territorial expansion. How the process of differentiation worked itself out in detail is obscure, but the main trends of the process are clear enough: they were the quantitative reduction of the Mediterranean and Paleo-European admixtures and the increase of the Nordic element. The territorial expansion of the Slavs effected a considerable change in the population structure of the area previously occupied by the Balts (*q.v.*); and west of the Oder the Slavs arrived in such great numbers that the subsequent German colonization caused no perceptible changes in the anthropological type. In the Balkans, though linguistic slavicization made great progress, the Slavic layer failed to submerge ancient anthropological differentiations, as the immigration was relatively small. In the Ukraine, which underwent many Asiatic invasions, the present anthropological situation is the result of a new wave of Slavic colonization that began in the 17th century, more or less simultaneously with the Russian penetration of Siberia, where anthropological slavicization is heavy because of the sparseness of the indigenous populations. (J. Cz.)

SLAV HISTORY AND CULTURE

Prehistory.—The original habitat of the Slavs, as of the ancestors of all other Indo-European speakers, was Asia. They migrated in the 3rd or 2nd millennium B.C. and, together with Balts, Scythians, and Sarmatians (*qq.v.*), populated eastern and central Europe. Archaeologically, it seems possible to trace the route of their migrations by finds of a painted pottery decorated with spirals and meanders, belonging to a culture that flourished between the Neolithic and Bronze ages. Balts and Slavs were originally members of the same linguistic family, but a differentiation started *c.* 1000 B.C., leading to the formation of two different linguistic groups.

In the basins of the Vistula and, chiefly, of the Oder River the so-called Lusatian culture was born (18th–8th century B.C.). Many archaeologists, anthropologists, and linguists identify this cultural area with the habitat of the early Slavs, but some archaeologists are inclined to associate it with other Indo-European peoples, above all with the Illyrians, or Veneti (*see* ILLYRIA), and to maintain that the original habitat of the Slavs was on the middle Dnieper River. There seems, however, to be no radical contradiction between the two theories. For in the whole area between the Dnieper and the Elbe and between the Baltic Sea and the Carpathian Mountains, the names of rivers and lakes are obviously of a common origin, and there is likewise much similarity among the various cultures found there. If the people of the Lusatian culture originally constituted a linguistic group distinct from the Balto-Slavs (though akin to them), it would seem eventually to have become totally subject to that influence, with the result that the Balto-Slavs of the Lusatian cultural area probably developed into the new ethnic and linguistic group known as Slavs or Wends.

Herodotus (5th century B.C.) seems to refer to Slavs in his description of Scythia when he mentions the Neuri living west of the middle Dnieper. Pomponius Mela, Pliny, Strabo, and Tacitus, writing in the 1st century A.D., give some information on Wends inhabiting an area along the Vistula River and on the Baltic shores. Ptolemy (2nd century A.D.) mentions the "considerable people" of the Venedai and the Venedic Gulf on the Baltic, by which he probably meant the Gulf of Danzig. By that time the Slavs were certainly inhabiting the area between the Dnieper and the Oder, the Vistula basin being their main habitat.

The Great Migrations.—The lands of the Slavs were crossed by many peoples forced by economic conditions to migrate. In the middle of the 1st millennium B.C. they were traversed by Celts and Germans on their way toward the Mediterranean and by Scythians and Sarmatians going to the Danubian basin. In the following centuries the Slavs were in cultural relations with these peoples.

Celtic tribes settled along the upper Oder (in Silesia) and Germanic tribes (Goths, Gepidae, Rugii, Vandals, and Burgundians) on the lower Vistula and lower Oder, usually without displacing the Slavs there. From the Goths the Slavs took many loanwords of cultural and social significance; *e.g.*, the Gothic *kuniggs*, "king," which became *knez*, "prince," in Slavonic. At the beginning of the 3rd century A.D. the Goths and the Gepidae left the lands of the lower Vistula and moved toward the Black Sea, by the shores of which in the 4th century they formed a powerful state in contact with the Slavic tribe of the Antae. Around 370 their state was invaded by the Huns (*q.v.*), who subdued Slavs and Germans alike.

The collapse of the Hunnish empire (455) and the departure of the Germans started the great migration of the Slavs. In the 6th century the historians Jordanes and Procopius divide the Slavs into three tribes, Antae, Sklaveni, and Venedi. The Antae were the East Slavs, the Sklaveni the South Slavs, and the Venedi the West Slavs. This division, however, was somewhat artificial, since at that time the Slavs still formed a very largely homogeneous community. Differentiation was the final result of the migration of groups of Slavs in three main directions: (1) westward, into the country between the Oder and the Elbe-Saale line; (2) southward, into Bohemia, Moravia, Pannonia (the later Hungary), Dalmatia, the lower Danube basin (Rumania), Bulgaria, and northeastern Greece; and (3) northward, along the upper Dnieper (*See* also EUROPE: *History: Greeks, Romans and Barbarians: The Migrations.*)

The First Organized States.—When the migratory movements had ended, there appeared among the Slavs the first rudiments of a state organization, headed by a prince with a treasury and a defense force, and a beginning of class differentiation. The Slavs formed such states somewhat later than the Germans did, as the latter had moved into territory where they inherited the forms of political organization from the Romans.

The oldest Slavic state was that of Samon or Samo, who at the beginning of the 7th century succeeded in grouping the Moravian and Czech tribes into a political unit as a result of a national rising against the Avars (*q.v.*). After Samon's death (658) the Moravians and the Czechs were again subjugated by the Avars. When the Avar state was finally destroyed by the Franks under Charlemagne (805), another Moravian, or Great Moravian, state was founded in the same area by Mojmir. Under Prince Svatopluk (870–894) this Great Moravia included the present Bohemia, Moravia, southwestern Poland, western Slovakia, and western Hungary. This state was destroyed in 907 by the Magyars. (*See* MORAVIA.)

The Catholic Franks and the Orthodox Byzantines had competed for influence in Great Moravia. The missionary work of Saints Cyril and Methodius (*q.v.*), though it failed along the middle Danube, led to the foundation of an Orthodox Church which

embraced the East Slavs and the more easterly South Slavs (Serbs, Macedonians, and Bulgars), while the West Slavs and the more westerly South Slavs (Slovenes and Croats) turned to Roman Catholicism.

The westernmost boundary of Slavic land was the Elbe-Saale line. The Polabian Slavs (*see* POLABS) living east of that boundary established their own principalities, the most important being those of the Lusatians, of the Obodrites, and of the Wilcy or Veleti. They all fell victims to the German ***Drang nach Osten*** or "drive to the East" in the 12th–13th centuries.

The *Drang nach Osten* may be regarded as a process continuing from the subjection of the Polabian lands by Germans in the Middle Ages to the participation of Prussia and of Austria in the destruction of Poland in the 18th century (*see* below). It affected all the Slavic lands, not excluding Russia. Military conquest was not the only form that it took: other aspects were settlement by German colonists, economic domination, and cultural influence. In the earlier period, contact with the German world was economically and culturally beneficial to the Slavs; but later subjection caused a strong national resentment.

During the 9th and 10th centuries, the Balkan Slavs, especially the Bulgars and the Croats, formed their own independent states. The first Bulgarian state (*see* BULGARIA: *History*) was founded in the 7th century by non-Indo-European invaders of Hunnish descent. They became slavicized, and under their tsar, Simeon the Great (893–927), who assumed the title of "emperor and autocrat of all of the Bulgars and Greeks," the Bulgarian empire became a civilized power. Destroyed in 1014 by the Byzantines, it was restored in 1185 to be destroyed again in 1392–96 by the Ottoman Turks.

On the territory of modern Yugoslavia the first Slavic kingdom was Croatia (*q.v.*), whose prince, Tomislav, received a royal crown from Rome (925). But conflicting influences—Orthodoxy and Catholicism on the one hand, the Holy Roman Empire, Hungary, and Bulgaria on the other—long prevented the Slavs of Yugoslavia from forming a unified independent state. In 1102 Croatia was united with Hungary, and this union eventually brought Croatia with Hungary to the Austrian Habsburgs. Slovenia (*q.v.*) had lost its independence much earlier, becoming a march or mark (frontier zone) of the Holy Roman Empire in the 10th century.

The first Serbian state was formed in the 9th century on the territory of the present Bosnia and Serbia (*see* BOSNIA-HERCEGOVINA; SERBIA). It became an empire under the Nemanya dynasty in the 12th century but was destroyed by the Ottoman Turks after the Battle of Kosovo (1389).

Magyars, Pechenegs, and Kumans (*qq.v.*) destroyed the Slavonic settlements in the present Hungary and Rumania. At the beginning of the 11th century Slovakia (*q.v.*) was also incorporated into Hungary.

The Czechs and the Poles succeeded in consolidating their independent states. Bohemia (*q.v.*) had to become part of the Holy Roman Empire in the 10th century, but in 1085, 1158, and 1198 the Přemyslide dynasty secured royal crowns, and under Přemysl Otakar I, in 1198, the royal title became hereditary. From 1310 the Bohemian throne was occupied by Germans of the Luxembourg dynasty. One of them, who became Holy Roman emperor as Charles IV in 1355, made Prague one of the foremost cultural centres of Europe. The Luxembourgs, however, lost Bohemia in 1419 during their wars against the Hussites (*q.v.*) who stood for Bohemian nationalism. In 1458 George of Poděbrady (*q.v.*) was elected king. After his death (1471) the Bohemian throne was coveted by Austria, Hungary, and Poland. Poland obtained it for Prince Wlandyslaw (Vladislav), son of King Casimir IV; but in 1526 it passed to the Habsburgs.

The cradle of the Polish state was Great or Old Poland (Wielkopolska, with Gniezno). Other parts were Small or New Poland (Malopolska, with Cracow), Silesia, Mazovia, and Pomorze. Unification was the work of the Piast dynasty, particularly of Prince Mieszko I (*c.* 962–992) and his son King Boleslaw I the Brave (992–1025); but Prince Boleslaw III the Wry-Mouthed (d. 1138) divided Poland among his four sons. The kingdom was restored in 1295, when Prince Przemysl II was crowned king.

Przemysl II's kingdom did not embrace Silesia or Mazovia (*qq.v.*), which remained autonomous under Piast princes. The Silesian princes subsequently recognized the suzerainty of the Bohemian crown, and Silesia passed with Bohemia to the Habsburgs in 1526 and was surrendered by them to Prussia in 1740. Mazovia, on the contrary, was reincorporated into the Polish realm by stages.

On the Baltic coast, Pomerania, or Pomorze (*q.v.*), was divided from 1181: both the western and the central part, under the Slavic dynasty of Gryf, had to accept the protection of the Holy Roman Empire, but the eastern or Vistulan part, with Gdańsk as its capital, remained linked with Poland—to become integrated with it in 1294. It was conquered by the Teutonic Order in 1308 but was returned to Poland in 1466. On the southern frontier, meanwhile, the principality of Halich-Volodymir (*see* GALICIA) was incorporated into the Kingdom of Poland in 1340.

In 1386, faced by a common German danger, Poland and Lithuania concluded a personal union under the Jagiello dynasty; and in 1569, to oppose Muscovite expansion, this union became a real one. It survived till the partitions of Poland among Russia, Prussia, and Austria in the last quarter of the 18th century (*see* POLAND: *History*).

The oldest state of the East Slavs was that of Kiev, in the Ukraine, formed at the end of the 9th century (*see* RUSSIAN HISTORY). Historians who argue that the first Russian state was a creation of Varangian (Norman or Scandinavian) rulers cannot deny that from the beginning this state was ethnically and culturally Slavic. Under its grand prince Vladimir the Saint (reigned 978–1015) the Rus—as the Kievan state was called—accepted Christianity from Byzantium in 988–89. Under Yaroslav the Wise (reigned 1019–54) the Rus attained considerable power, and Kiev became the great metropolis between Constantinople and the Baltic. In 1240 the Tatars destroyed the Kievan state, and the Russian princes became vassals of the Golden Horde. (*See* MONGOL EMPIRES.)

While the Tatar yoke paralyzed the development of Russian culture for two centuries, the principality of Moscow rose to political importance (*see* MOSCOW, GRAND PRINCES OF). In 1472, less than 20 years after the fall of Constantinople to the Turks, the grand prince of Moscow, Ivan III the Great, married Zoë (Sophia) Palaeologus, niece of the last Byzantine emperor; and in 1480 Ivan proclaimed himself "autocrat of all Russia" and declared Moscow to be the "Third Rome." Ivan IV the Terrible was crowned as first "tsar of all Russia" in 1547. The 17th century saw the settlement of Russians and Ukrainians in Siberia (*q.v.*) and in the steppes north of the Black and the Caspian seas. Peter (*q.v.*) the Great, who proclaimed himself emperor in 1721, and the empress Catherine II (*q.v.*) the Great, who reigned from 1762 to 1796, consolidated Russia's position as a great power. At the beginning of the 19th century Russia was the only independent Slavic state in the world.

Political Restoration in the 19th and 20th Centuries.—The weakness of the Ottoman Empire at the end of the 18th century, together with the conflicting interests of the Great Powers in the area controlled by it, led to the restoration of Slavonic states in the Balkans (*see* EASTERN QUESTION). Serbia, proclaimed autonomous in 1830, became independent and territorially aggrandized in 1878 and was declared a kingdom in 1882. It was further aggrandized through the Balkan Wars (*q.v.*) of 1912–13, which also gave an extension of territory to Montenegro (*q.v.*), a small state independent from 1878 and a kingdom from 1910. After World War I, Serbia, with an expanded area that included Montenegro, merged itself into the Kingdom of the Serbs, Croats, and Slovenes, which in 1929 changed its name to Yugoslavia. Bulgaria, meanwhile, having become autonomous under Ottoman suzerainty in 1878 and having extended its control over Eastern Rumelia in 1885, had become an independent kingdom in 1908 and had also expanded as a result of the Balkan Wars.

Poland's struggle to recover independence found a powerful echo among other Slavic nations, especially the Czechs and the Slo-

vaks. Toward the end of the 19th century, in Russian Poland, it assumed partly a social revolutionary character, whereas in Prussian and in Austrian Poland the movement was essentially national. Nationalism was also the main force in the resistance of other Slavs within the Austro-Hungarian monarchy—Czechs, Slovaks, Croats, and Slovenes. The defeat of the Central Powers in World War I led to the restoration of Poland, as well as to the creation of Czechoslovakia and of the Kingdom of the Serbs, Croats, and Slovenes.

Culture.—The oldest forms of Slavic culture, material, social, and spiritual, are known somewhat superficially from archaeological discoveries. The higher forms of that culture are closely linked with the spiritual life (religious cults, the cult of ancestors, and sacred architecture), a link that persisted for many centuries and was especially strong in the Middle Ages. Moreover, the most ancient writings are concerned with religious life. Only when the first organized states emerged did any historiography appear, as well as collections of laws. The Slavs of the Orthodox Church early began to write in their national languages, particularly the Russians and the Bulgars; but the Roman Catholic Slavs wrote in Latin till the Reformation.

The lay trend in Slavic culture is above all represented by popular arts. Its beginnings can be traced in prehistoric remains, and its development, not only in the plastic arts but also in music and in poetry (songs, ballads, and epics), ran parallel to that of the work produced for the church or for the upper classes. Popular poetry flourished everywhere among the Slavs, most richly in Russia and in the Balkans.

For the literature of the East Slavs *see* Russian Literature and Ukrainian Literature; for that of the West Slavs, Czechoslovak Literature and Polish Literature; for that of the South Slavs, Bulgarian Literature and Yugoslav Literature. The Slovak poet Jan Kollár was a pioneer exponent of Pan-Slavism (*q.v.*), while the reactionary Slavophils (*q.v.*) tried to persuade non-Russian Slavs that "Holy Russia" was their motherland.

Slavic music owes very much to popular inspiration: Frédéric Chopin, Aleksandr Borodin, Mikhail Glinka, Modest Mussorgsky, Nikolai Rimski-Korsakov, and Bedrich Smetana provide examples. In painting, Jan Mateiko in Poland and Ilya Repin in Russia are famous for their scenes of national history. Among sculptors, the Croat Ivan Mestrović is universally known. In the physical sciences were the astronomer Copernicus and the radiologist Marie Curie (née Sklodowska). Among Russian scientists the polymath Mikhail Lomonosov, the mathematician Nikolai Lobachevski, the chemist Dmitri Mendeleyev, and the physiologist-psychologist Ivan Pavlov must be mentioned here. Among the Czechs, Jan Purkyně (Purkinje) and Jiří Procházka were both important physiologists.

SLAVYANSK, a town of the Donetsk (formerly Stalino) Oblast' of the Ukrainian Soviet Socialist Republic, U.S.S.R., stands at the confluence of the Kazënnyy Torets and Sukhoy Torets, tributaries of the Severnyy (Northern) Donets. Pop. (1959) 82,784. The town is the main centre of the northwestern part of the Donets Basin (Donbass) industrial area. The presence of saline and mud springs and of rock salt and coal makes Slavyansk an unusual combination of health resort and industrial town. There is an important chemical industry, producing chiefly caustic soda. Armatures, other machinery, and pencils are also made. Slavyansk has a peat-burning power station. The town was founded in 1676. (R. A. F.)

SLEEP is a recurring state of inactivity, decrease of consciousness and decrease in responsiveness to events in the environment. The ease with which sleep can be terminated differentiates it from coma, general anesthesia, alcoholic stupor and the seasonal lethargy of certain animals (*see* Hibernation and Estivation). On the other hand, there are conditions of semiawakeness ("brown study," postepileptic automatism, hypnotic trance, fugue, etc.) that are intermediate in character, possessing some features of both sleep and wakefulness. Moreover, in the routine of living there are regular diurnal gradations in the depth of slumber and the degree of alertness, which alternate with each other like the crest and trough of a 24-hour wave.

From observation and experiment, theories of sleep have been elaborated and a hygiene of sleep developed.

Observational Data.—A conspicuous characteristic of sleep, for man and many animals, is the horizontal posture of repose which permits a relaxation of the body musculature. When a person is awake, muscular contractions not only produce overt movements but also maintain station, or posture, through tonic activity —a state of partial contraction which manifests itself in resistance to passive or externally imposed movement. In raising gently an arm of a sleeping person, however, little opposition is met, and when the grip on it is released, the arm drops back limply. A rather annoying (to others) aspect of this general relaxation of sleep is that it also involves the muscles of the jaw, causing the mouth to open; and then the soft palate, with its appendage, the uvula, flutters with passage of the air in and out of the lungs, producing the well-known sounds of snoring.

Muscles are supplied with two types of nerve fibres: (1) efferent, motor, centrifugally conducting fibres, which carry impulses from the nervous system, resulting in overt as well as tonic contractions; and (2) afferent, sensory, proprioceptive ("self-feeling"), centripetally conducting fibres, which furnish conscious and unconscious information concerning the state of the different parts of the body and their relation to each other. This muscle sense, literally a sixth sense, contributes greatly to the continuous stream of afferent impulses from the sense organs to the cerebral cortex. In order to sleep, a person shuts off the streams of visual and auditory impulses by retiring to a dark, quiet room, and decreases cutaneous impulses by lying down on a soft, smooth surface, but the proprioceptive impulses, coming as they do from the body itself, are still there, gradually decreasing only when and as the body musculature is relaxed.

Muscular relaxation and immobility, however, are not absolute. From time to time, unless mechanically restrained, the sleeper moves one part of the body or another, or turns over completely changing his position. A person's positional repertory may be small or large, and the total amount of motility varies with the degree of fatigue, environmental temperature, amount of bed coverings, width of the bed and the quantity and composition of food and beverage taken before going to bed. As a rule, the longer the duration of sleep, the greater the frequency of movement. Occurring altogether about 20 to 40 times in the course of one night, this motility entails at least a semiawakening and a partial awareness of external relations. The sleeper does not usually recall these multiple interruptions of rest, and the total time spent in motility is small, amounting to about 30 seconds per hour, or a few minutes for a whole night's sleep. The periodic change in the position of the body is probably brought on by, and relieves, the pressure on the skin in contact with the bed surface. Alcoholic intoxication, deadening sensitivity to discomfort, leads to decreased motility during sleep, often resulting in soreness and stiffness in a muscle or even a partial paralysis from pressure exerted on a nerve for several hours.

It is possible to sleep in a semireclining position (as on a reclining chair), sitting upright (at a lecture, theatre or in an easy chair at home) or, when very tired, while standing up or riding horseback. Some animals regularly sleep in a standing position.

Of greatest interest are the changes in the activity of the nervous system during sleep. In older children and adults this manifests itself in the abolition, or at least depression, of critical reactivity to external events. In the waking state the impulses coming from the different sense organs to certain areas of the cerebral cortex are analyzed in the light of the person's previous experience, and appropriate responses (which include movement

as well as refraining from overt muscular activity) are elaborated or integrated in other cortical areas. Identical afferent impulses from sense organs will not elicit the same response in different persons. This individuality of reaction is lost during sleep and is replaced by stereotyped predictable reflexes from the lower centres of the nervous system. Furthermore, compared with wakefulness, the reflex excitability of the lower centres themselves is decreased during sleep. A more powerful stimulus is required to obtain a response of a certain magnitude.

During sleep the amplitude and frequency of the electrical brain waves undergo characteristic changes, and it has been possible to associate particular electroencephalogram (EEG) patterns (*see* ELECTROENCEPHALOGRAPHY) with certain stages of sleep. Epileptic persons show typically peculiar brain waves while awake, but even more revealing are their EEGs during sleep. Furthermore, whereas an epileptic fit in the waking state is almost always ushered in by a definite EEG complex, the same complex in sleep does not lead to overt convulsions unless the sleeping epileptic is awakened at that time. This suggests that in sleep there may be a functional de-efferentation of the lower centres of the nervous system.

In contrast to the general inactivity, muscular relaxation, lack of critical reactivity, and depression of reflex excitability—all involved in the external or animalistic relations of the organism—the internal, household, visceral or vegetative functions are either unaffected or somewhat enhanced during sleep. Circulation of the blood goes on, although the heart rate is decreased and the arterial blood pressure lowered. These changes are in part related to the assumption of the horizontal position, and often occur upon simply lying down and remaining awake. In sleep there are also modifications in the rate and depth of respiration, indicative of a decreased excitability of its regulating centre, along with that of other reflex centres, in the nervous system. As a result there are certain changes in the composition of the blood, which is less thoroughly purified than in the waking state. Digestion—the movements of the different parts of the gastrointestinal tract and the secretory activity of its glands—goes on unabated. The same seems to be true of the liver and kidneys, although some decrease has been detected in the functioning of these vital organs, as well as in the metabolic rate (oxygen consumption) of the organism. There is a marked drop in body temperature, often amounting to 1° F., which is undoubtedly related to muscular relaxation and a lowering of metabolic processes. Sweating, in general, as a means of cooling off the body by evaporation, may actually be accentuated during sleep, especially in warm weather, but is diminished in skin areas of the palms of the hands and soles of the feet.

Variation in each of the above-enumerated concomitants of sleep in the course of the night has been employed as an index of its depth. Unfortunately, there is no agreement among the several depth-of-sleep curves constructed in this manner. The most commonly used method is to determine the loudness of a sound required to awaken the sleeper. The figures obtained suggest that during the night sleep gets to be very deep in the first two or three hours and then becomes progressively lighter. Similar curves could be derived from data on quiescence (the reverse of motility), the increase in the carbon dioxide of the air in the lungs and the predominance of slow (3 to 0.5 per second) delta EEG waves. Using arterial blood pressure or body temperature as a criterion, sleep is deepest in the middle of its course. Lastly, the lowest heart rate is not reached until the sixth or seventh hour of sleep. Thus, by proper selection of an index, it can be shown that sleep is deepest in the first, second or third quarter of the night. More important, study of the figures on which the different curves are based reveals that in any one night there may be repeated fluctuations in the depth of sleep. Instead of one curve there are several—each representing a basic rest-activity cycle. This cycle, first detected in the sleep of infants, in whom it repeats itself every 50–60 minutes, gradually lengthens to 80–90 minutes in adults. In young kittens the short-term sleep cycle is 20–30 minutes; in mature cats, 30–45 minutes.

One phase of the repetitive depth-of-sleep wave has been called paradoxical, because it is characterized by an EEG fast-activity pattern usually seen in wakefulness, yet the sleep is very deep, as judged by the intensity of the stimulus required to awaken the animal. In man the corresponding phase of the short-term sleep cycle shows a modified alpha EEG pattern, somewhat irregular and a trifle slower than the waking EEG. This phase may be termed quasi-paradoxical: using a neutral sound to arouse the sleeper, the intensity needed is very high, suggesting deep sleep of the delta EEG pattern; but with a meaningful sound stimulus, *e.g.*, the subject's name or a modulation indicating punishment for failure to respond, the sleeper can be awakened as easily as in the early light stage of sleep. During the quasi-paradoxical phase there are, in addition to the modified alpha EEG, cardiac and respiratory accelerations as well as bilaterally synchronous rapid eye movements (REMs), distinctly visible even under closed eyelids but also recordable electronically as changes in the corneoretinal potential.

If the sleeper is awakened during this phase of the short-term cycle, he nearly always reports dreaming, but rarely does so in other phases of the cycle. The quickening of the pulse and breathing may be related to emotional elements of the dream episode, and the REMs probably represent scanning the scene of dream action, as their direction conforms to the movements of objects and persons seen in the dream.

The length of the dream story is proportional to the lapse of time between the appearance of the modified alpha EEG and the arousing and questioning of the sleeper. Contrary to anecdotal reports, the course of time during dreaming is about the same as in real life. Sound or light stimuli too weak to awaken the sleeper, if applied while dreaming is in progress, are occasionally incorporated into the dream story. After the cessation of the objective signs of dreaming, the ability to recall details of the dream content rapidly diminishes, and in a few minutes the sleeper may forget that he dreamed at all. That explains why many persons maintain that they seldom, or never, dream. However, even the latter invariably recall dreaming if aroused while showing a modified alpha EEG sleep pattern. The objective criteria of dreaming can be used to plot the incidence and duration of dreaming episodes during a night of undisturbed sleep. There are usually five or six periods of dreaming, the first, and shortest, occurring about one hour after the onset of sleep, and the succeeding ones, corresponding to 80- to 90-minute cycles of EEG pattern variation, progressively longer. The average duration of dreaming periods is from 5 to 50 minutes, with a total of about two hours for a whole night's sleep. (*See* also DREAM AND DREAMING.)

Experimental Data.—Sleep deprivation (keeping a person awake by constant watching and prodding) has been a favourite method used in study of the sleep problem. After about 60–90 hours of enforced wakefulness (four to six times the usual span of 16–17 hours), the most prominent effect is extreme muscular weariness. The subjects of such experiments want most to be allowed to close their eyes and lie down, but it is precisely this enforced muscular activity that enables them to remain awake. Lying down means failure of the experiment. Nothing is more illustrative of the importance of proprioceptive impulses in the maintenance of wakefulness and of muscular relaxation in the precipitation of sleep.

Among other features of behaviour in sleep deprivation are irritability to the point of irascibility in normally even-tempered subjects, and a mental disorganization, leading to dreaming while awake, hallucinations and automatic behaviour, occasionally bordering on temporary insanity. It is easy to understand why the third-degree method of continuous interrogation for many hours will make a person sign a "confession," even if innocent of the crime he is accused of having committed. He wants to be permitted to sleep, and he fails to realize the seriousness of his self-incrimination.

Experiments on animals include inducing lesions in, and stimulation of, different parts of the central nervous system. Dogs surgically deprived of the cerebral cortex still show alternation of sleep and wakefulness. Such decorticated animals lose the greater

part of their learning ability and no longer profit from their previous experience. They would starve to death, in the presence of an abundance of food and water, unless artificially fed. They do not recognize their keeper, and their behaviour in many ways resembles that of very young puppies. Like the latter they go to sleep after they are fed, become restless only when hungry, and their sleep-wakefulness cycle loses its usual relation to night and day.

Nature performs similar experiments on human beings, in the form of anencephalous infants (born without a cerebral cortex) who often remain alive for months or even years. Unlike normal infants, who learn in a few weeks to consolidate several short naps into one long night's sleep, anencephalous ones, as long as they live, sleep at irregular intervals. Their sleep-wakefulness cycle, like that of decorticated dogs, seems to be geared largely to the satisfaction of hunger. Evidently, primitive sleep-wakefulness alternation does not require cerebral cortical activity in either animals or man.

By modern electrocoagulation procedures, it is possible to burn out discrete regions of the brain stem without removing or injuring the cerebral cortex. Extensive damage to the hypothalamus, in the region of the mammillary bodies, in cats and monkeys induces profound somnolence or frank sleep. It would appear that the waking state is maintained by impulses sent from the hypothalamus to the lower centres of the nervous system. Conversely, afferent impulses from the periphery are capable of stirring the wakefulness centre of the hypothalamus into activity. Again, nature's experimentation, in the form of lethargic encephalitis (sleeping sickness), seems to confirm the laboratory findings. In the latter disease the cerebral cortex is undamaged, but there are extensive lesions in the brain stem in the region of the wakefulness centre. Significantly, sleeping sickness patients can at times be aroused briefly, but they are unable to maintain wakefulness. No naturally occurring destruction in the brain stem or elsewhere in the nervous system has ever produced permanent insomnia, militating against the existence of a sleep centre.

A sleep abnormality that points to the importance of afferent impulses from the sense organs in wakefulness is narcolepsy, a disease in which bouts of almost uncontrollable drowsiness may occur several times daily for years. The incidence of these attacks increases when the narcoleptic is alone and is engaged in uninteresting activity, conditions conducive to drowsiness in nearly everyone. Of added interest is that narcolepsy is usually associated with cataplexis, a sudden complete loss of muscle tonus, causing the person to sink to the ground, with consciousness usually preserved. This sudden muscular relaxation, seldom lasting more than a few minutes, is brought on by some emotional stress, particularly laughter. The causes of narcolepsy and cataplexis are unknown, but their occurrence in combination suggests that a defect in the maintenance of tonus in the skeletal musculature and failure, at times, of wakefulness may have a common cause.

Theories of Sleep.—Partial theories pertain to the mechanism of going to sleep and attempt to explain how sleep is brought about; awakening is usually ascribed to a reversal of the changes that produce sleep. General theories deal with the reason for sleep, often without attention to the mode of its onset or termination. Complete theories try to explain both the mechanisms of and reasons for the phenomenon, sometimes by proposing the same scheme for both.

Circulatory theories, of the partial kind, ascribe sleep to a shifting of the blood out of or into an important organ, usually the brain. These theories are obsolete, as the absence of such a shift of blood has been definitely established. Also discarded are the neural theories, postulating a physical break in the chains of nerve cells that serve as conducting pathways in the nervous system. Inhibitory theories implicate widespread inhibition which decreases or abolishes the activity of the cerebral cortex, but they are clearly inadequate when it is considered that decorticated animals and newborn infants (whose cerebral cortex is not yet functioning) can sleep. Deafferentation theories are based on the fact that shutting off incoming sensory impulses to the cerebral cortex is incompatible with wakefulness, but they likewise fail to explain sleep after decortication. Biological theories are general in that they consider sleep an instinct and, as such, a positive act rather than a mere cessation of wakefulness. The vagueness of these theories is at once a strength and weakness; it is impossible either to refute them or to prove their correctness. Humoral or chemical theories stem from established changes in the composition of the blood and urine, modification of metabolic processes in the tissues and a possible variation in the secretory activity of the glands of internal secretion, occurring during sleep as compared with wakefulness. Either some substance required to maintain the waking state is exhausted, and sleep serves to replenish it; or, on the contrary, some toxic substances accumulated in wakefulness are excreted or destroyed in sleep. However, alertness and efficiency of performance are not at their best at the time of getting up in the morning, nor at their worst at bedtime at night.

An evolutionary theory distinguishes between the roles of the hypothalamic centres and the more recently evolved cortical centres in the maintenance of the waking state. According to this theory, sleep as a state of inactivity requires no explanation. Wakefulness of the primitive type, seen in the newborn infant or in decorticated animals, designed to meet the minimum needs for keeping alive and for protoplasmic growth, is a subcortical, probably hypothalamic, function. The higher type of wakefulness, with its attendant alertness, critical reactivity and wider interests, as well as the adaptation of the sleep-wakefulness cycle to the 24-hour alternation of night and day, is a function of the cerebral cortex. Wakefulness maintained by the cortex depends upon its receiving impulses from both the hypothalamic centres and the sense organs, particularly the skeletal muscles.

Hygiene of Sleep.—Although no proposed theory of sleep has met with universal acceptance, enough factual information is available for a rational hygiene of sleep. Acculturation to the family and community pattern of living begins at a very early age. Even in the first few days of life the human infant sleeps more at night than in the daytime. A continuous long period of sleep at night is achieved, with some training, in two or three months. Supplementary daytime naps are reduced to two at six months (by which time a distinct diurnal body temperature curve is in evidence) and to one by the end of the first year; they are given up entirely at the age of three to six years. The belief that very young babies sleep nearly all the time—about 20 or 22 hours out of 24—has been shown to be incorrect. The average total duration of sleep of a newborn infant is only about 14–15 hours and this is reduced to 13–14 hours at the age of six months. Thereafter there is a continuous decline to 7–9 hours of sleep per 24 hours in the adult.

The nightly sleep "ration" is made up of two components: an obligatory need for sleep, which varies with the physical, mental and temperamental characteristics of the individual, and an accessory indulgence in sleep, influenced by age, sex and day-to-day fluctuating environmental factors. A person's irreducible sleep fraction is best expressed by its complement, the maximum sustainable duration of wakefulness. At one extreme of the population distribution are persons capable of remaining alert for more than 18 hours daily, at the other those who succumb to uncontrollable drowsiness in less than 14 hours. Everyone, however, tends to overindulge in sleep in the absence of stimulating events in his immediate environment, simply as an escape from boredom. Thus, in routine uninteresting existence most people sleep longer than is necessary for their well-being. By the purely empirical test of freedom from sleepiness during the customary waking hours, each person can determine his minimum sleep requirement.

Although sleep is in no sense a habit, the adjustment to hours of retiring and getting up, to certain types of bed and bedding and to a host of environmental conditions depends on individual experience and training. The diurnal sleep-wakefulness rhythm, it will be recalled, is cortically conditioned, and by following a regular schedule of hours for various tasks and recreation, meals and sleep, this rhythm is fortified. The reward is twofold: (1) a

more prompt occurrence of sleep at night and spontaneous awakening in the morning, and (2) greater alertness during wakefulness, especially at customary hours of activity.

Insomnia usually involves a difficulty in falling asleep. When it is caused by pain or physical discomfort, a hypnotic drug, prescribed by a physician, may have to be resorted to. Occasionally, grief over past events or worry over possible future misfortunes produces a muscular tension that prevents the onset of sleep. Under these conditions, anything that takes a person's mind off the disturbing thoughts promotes muscular relaxation and is thus conducive to sleep. A series of routine chores, such as grooming and bathing, for an hour or two before going to bed helps induce drowsiness. Reading in bed (if the subject matter is not emotionally charged) or listening to soothing music is soporific for some persons. However, what puts one person to sleep may keep another awake.

A particular difficulty faces those who are engaged in around-the-clock operations of some industries, public utilities, transportation and communication companies, police and fire departments, hospitals and military services. These persons have to work (and therefore also sleep) at unconventional hours and are subject to many inconveniences. The common practice of rotating work shifts at frequent, often weekly, intervals all but prevents the workers from developing a suitable individual sleep-wakefulness rhythm.

The temperamental make-up of the individual also affects his ability to conform to the community pattern of living. Early to bed and early to rise is easy for the "morning" type, whose body temperature and efficiency reach their maxima around noon. A marked "evening" type dislikes getting up at the conventional hour in the morning, depends upon an artificial mode of awakening, does not reach his height of efficiency until late in the afternoon (when the work day is practically over) and hates to go to bed at night. A satisfactory adjustment can be made by nearly everyone, though not with equal ease.

SLEEPWALKING: *see* HYPNOSIS; HYSTERIA.

SLEET, in the United States and Canada the popular name for precipitation of transparent, roundish, hard ice particles one to four millimetres in diameter, which in other countries are properly called grains of ice, ice pellets or frozen raindrops. These are often confused with graupel, small hail, soft hail, granular snow and snow pellets, which resemble ice pellets somewhat in size and general appearance but are whitish, softer and less dense. Ice pellets mixed with rain and falling on surfaces having temperatures below freezing result in a pebbly surfaced crust of glaze (clear ice) forming over the surfaces.

Ice pellets are produced by raindrops formed in clouds in an upper warm-air layer becoming frozen while falling through a lower (or surface) air layer having a temperature well below freezing.

In British countries (except Canada) sleet refers to a mixture of rain and snow. *See* HYDROMETEOR. (R. G. SE.)

SLEIDANUS, JOHANNES (1506–1556), German historian, the Protestant annalist of the Reformation, whose account remained a basic work until the archives were opened in the 19th century, was born near Aachen at Schleiden, from which his name was later taken (his father's name was Philippi). From 1533 to 1542 he studied classics and law in France, adopting Protestant opinions about 1541. He was an intermediary in Francis I's futile negotiations for an anti-Habsburg alliance with the princes of the Schmalkaldic League and in 1545 ambassador for those princes in England. From 1551 to 1552 he represented Strasbourg and other imperial cities at the Council of Trent. He died in Strasbourg on Oct. 31, 1556.

Martin Bucer had proposed to Philip of Hesse that Sleidanus be appointed historian of the Reformation, with a salary and access to documents, and the work—*De statu religionis et reipublicae Carolo V Caesare commentarii*, the first account of the Reformation to be based on documents (primarily those of Hesse and Strasbourg), and including many excerpts—appeared in 1555; a 26th book was added posthumously in 1558, bringing events up to 1556 (English translation 1560, 1689). The work pleased nobody: Catholics, then as later, complained of bias, while few of the Protestant princes could welcome so frank an account. Even Melanchthon sighed that Sleidanus had told much that had been better buried in eternal silence.

A convinced believer in the divine nature of the Reformation, Sleidanus nevertheless made a real attempt at objectivity, in spite of a perhaps historically inevitable failure to understand the motives of the papacy and the emperor. His book is the work of a layman versed in imperial law. In the line, though hardly of the stature, of Machiavelli, he views the state as an organism independent of the church and brings out the political and European aspects of the religious conflict. Sleidanus wrote also *De quattuor summis imperiis* (1556; English translation 1563), a textbook of universal history widely used up to the 18th century.

SLESSOR, SIR JOHN COTESWORTH (1897–), British air marshal, was born at Rhanikhet, India, on June 3, 1897, and educated at Haileybury College, Hertfordshire. In 1915 he was commissioned in the Royal Flying Corps and served as a pilot in France, Egypt, and the Sudan. Appointed to a permanent commission in the Royal Air Force in 1920, he served two years in India and afterward in various home appointments. In 1935–37 he commanded the wing supporting the Indian army in the Waziristan operations, and for this service was awarded the distinguished service order. On his return to England he served as director of the plans branch of the Air Ministry. In 1940, during World War II, Slessor visited the United States on a special mission. In 1942 he took the new and important post of assistant chief of the air staff (policy), and attended the chief Allied conferences. The following year he was appointed air officer commander in chief, Coastal Command, and was able, in close cooperation with the Royal Navy and the U.S. forces, to contribute to the defeat of the German submarines in the Battle of the Atlantic. In 1944 he became deputy air commander in chief of the Allied forces in the Mediterranean and a year later was made air member for personnel on the Air Council. In 1948 he became commandant of the Imperial Defence College before holding the highest of all posts in the RAF—that of chief of the air staff. He retired in 1952.

Air Marshal Slessor became well known also for books and articles on air strategy. He was created knight grand cross of the Order of the Bath in 1948. His book *The Central Blue* is largely autobiographical. (E. B. BN.)

SLEZAK, LEO (1873–1946), Czech tenor known for his performance of Wagnerian operatic roles, was born at Sumperk, Moravia, on Aug. 18, 1873. He studied under Adolf Robinson and made his debut at Brno in *Lohengrin* in 1896. In 1908 he studied under Jean de Reske in Paris and in the following year established his reputation as a heroic tenor in the part of Othello in London and New York, his impersonation being helped by his imposing height. He was later esteemed for his interpretations of Wagnerian roles throughout Europe and the U.S. In later years Slezak abandoned singing and became known as a film comedian in Austria. He died at Egern, Bavaria, on June 1, 1946. His son, WALTER (1902–), became a well-known U.S. actor.

See L. Slezak, *Song of Motley* (1938); W. Slezak, *What Time's the Next Swan?* (1962).

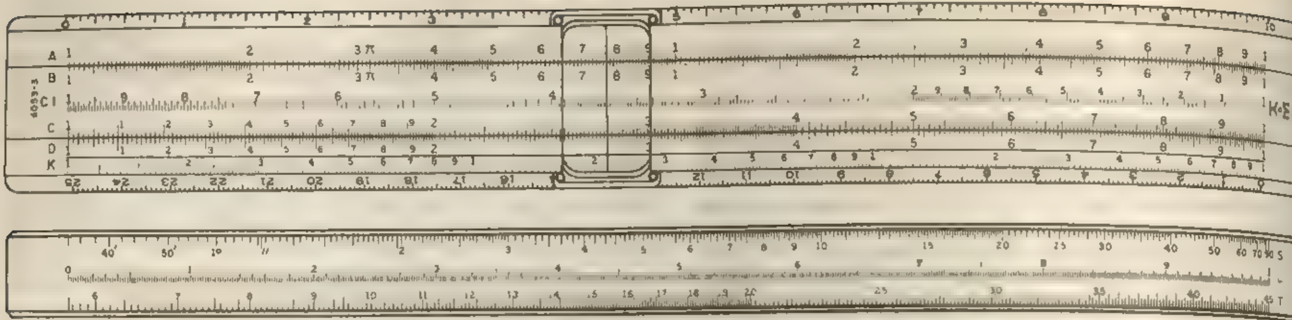
SLIDE RULE, a rule consisting of graduated scales capable of relative movement, by means of which simple calculations may be carried out mechanically. In ordinary slide rules these operations include multiplication, division and extraction of square roots, as well as, in some cases, calculation of trigonometrical functions and logarithms. The slide rule has become an essential



BY COURTESY OF KEUFFEL & ESSER CO.

FIG. 1.—MANNHEIM SLIDE RULE

tool in the mathematics of science and engineering and is widely used in business and industry as well.

The logarithmic slide rule is a compact device for rapidly performing calculations with limited accuracy. The invention of logarithms in 1614 by John Napier of Merchiston, Scot., and the computation and publication of tables of logarithms made it possible to effect multiplication and division by the simpler operations of addition and subtraction. (*See* LOGARITHMS.) Napier's early conception of the importance of simplifying mathematical calculations resulted in his invention of logarithms, and this invention made possible the slide rule as we know it. In 1620 Edmund Gunter plotted logarithms on a two-foot straight line. With such scales, multiplication and division were performed by addition and subtraction of lengths by a pair of dividers.

William Oughtred, according to his own statement (1633), constructed and used as early as 1621 two of these Gunter's lines sliding by each other so as to do away with the need for dividers. The lines were used in both the straight and circular forms. In the former the scales were held against one another by the hands; in the latter, dividers were replaced by an "opening index"—really a pair of dividers fixed centrally on the circular scale. Oughtred's two scales were the forerunners of the C and D scales, the basic scales on nearly all slide rules from then on.

The first known slide rule in which the slide worked between parts of a fixed stock was made by Robert Bissaker in 1654. Others were due to the enterprise of Seth Partridge (1657), Henry Coggeshall (1677)—a slide in a two-foot folding rule adapted to timber measure—and Thomas Everard (1683) for gauging purposes. The usefulness of the slide rule for rapid calculation became increasingly recognized, especially in England, during the 18th century, and the instrument was made in considerable numbers, with slight modifications.

Improvements in the direction of increased accuracy in graduation, etc., were initiated by Matthew Boulton and James Watt from about 1779 in connection with calculations in the design of steam engines at their works at Soho, Birmingham.

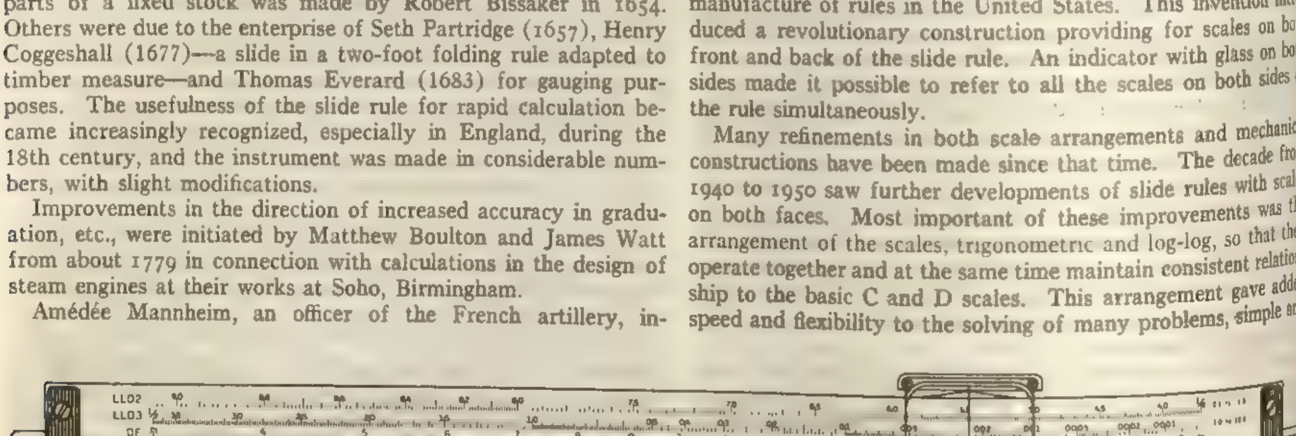
Amédée Mannheim, an officer of the French artillery, invented in 1859 what may be considered the first of the modern slide rules. This rule had scales on one face only and although it was quite simple is basically of a type still made and designated by his name. The disposition of the scales in the Mannheim rule is the arrangement still adopted in the great majority of rules made in the 20th century (*see* fig. 1). This rule, which also brought into general use a cursor, or indicator, was much used in France, and after about 1880 was imported in large numbers into other countries.

Up to this period the rule had been constructed usually of boxwood and occasionally of brass or ivory, but a great improvement was introduced in 1886 by Dennert & Pape in Germany by dividing the scales on white Celluloid, which gave a much greater distinctness in reading. This material was later almost universally adopted, and the slide rule attained a high degree of perfection.

In 1815 Peter M. Roget invented his "log-log" slide rule for performing the involution (*q.v.*) and evolution (*q.v.*) of numbers (*see* fig. 2). The fixed scale, instead of being divided logarithmically, is divided into lengths which are proportional to the logarithm of the logarithm of the numbers indicated on the scale; the sliding scale is divided logarithmically.

Before 1890 slide rules were made only in England, France and Germany, but at that time an invention by William Cox led to the manufacture of rules in the United States. This invention introduced a revolutionary construction providing for scales on both front and back of the slide rule. An indicator with glass on both sides made it possible to refer to all the scales on both sides of the rule simultaneously.

Many refinements in both scale arrangements and mechanical constructions have been made since that time. The decade from 1940 to 1950 saw further developments of slide rules with scales on both faces. Most important of these improvements was the arrangement of the scales, trigonometric and log-log, so that they operate together and at the same time maintain consistent relationship to the basic C and D scales. This arrangement gave added speed and flexibility to the solving of many problems, simple and



COURTESY OF KEUFFEL & ESSER CO.

FIG. 2.—THE LOG-LOG SLIDE RULE: TOP, FRONT FACE; BOTTOM, REVERSE FACE

complex alike, since it produced solutions by continuous operation, without the need of intermediate readings.

(A. W. K.)

SLIEMA, a town of Malta and a suburb of Valletta, the capital, lies on a headland that forms the northwesterly approach to Marsamxett (Marsamuscetto) harbour. Pop. (1961 est.) 24,014. The town has two aspects, one facing Valletta southward across Sliema creek with Fort Tigné dominating the entrance and the other looking northward over the Mediterranean. Sliema is perhaps the most English part of Malta, but there is a reminder of other days in the watch tower against corsairs on the northern sea front. A large number, at times a majority, of its inhabitants are British servicemen (both naval and military) and officials.
(W. B. Fr.)

SLIGO (Contae Shligigh), a county of the Republic of Ireland in Connaught Province, covers 693 sq.mi. (1,795 sq.km.). It is varied in scenery and one-third is rough pasture, chiefly in the mountains and hills and in the lowland peat bogs. On the east the boundary with County Leitrim runs south through the coastal lowland, about 5 mi. wide, to the fine upland of the Dartry Mountains (Ben Bulbin, 1,722 ft. [525 m.]), which is made up of limestone and has spectacular scarped edges. The boundary then crosses Glencar and another area of plateau to Lough Gill, a lake surrounded by hills and having rich woods which include the arbutus, or strawberry tree, with oak and birch. The little island of Innisfree, made famous by the lyric of W. B. Yeats, is in Lough Gill. To the south of Lough Gill there is a long ridge broken by gaps called *alts* of which one, at Collooney, carries the main road and railway north to Sligo. West of this gap the ridge, formed of ancient sedimentary and metamorphic rocks, becomes the Ox Mountains, a peat moorland 7 to 10 mi. wide and rising above 1,700 ft. (518 m.) (Knockalongy, 1,778 ft. [542 m.]). These mountains have the northeast–southwest, or Caledonian, trend so prevalent in Ireland.

In the area north of the Ox Mountains there is a continuously farmed lowland, 2 to 5 mi. wide, from the mouth of the River Moy to the Leitrim border. Sligo Bay has three long estuaries leading to Drumcliff, Sligo, and Ballysodare, which receive the waters of the Drumcliff, Garavogue, and Owenmore rivers. There is a long tradition of fishing, but only salmon is profitable now: a limited number of coasting steamers come to the port of Sligo. The lowland is divided into small farms, mainly of 25–30 ac. (10–12 ha.) but formerly much smaller, which depend on cattle, sheep, and poultry. Peat is cut in the neighbouring plateau areas and, especially, the Ox Mountains. Noted tourist resorts are Rosses Point, with a famed golf course, and Strandhill beside the isolated hill of Knocknarea (1,078 ft. [329 m.]). Some of the valleys have farms, but the Ox Mountain ridge makes an almost complete break between the inland and the coastal areas of the county.

Inland from the Ox Mountain ridge, the eastern boundary with Leitrim strikes southeast across the plateaus and then bends southwest through varied country to Lough Arrow, crosses the Curlew Hills (828 ft. [252 m.]) to Lough Gara, and finally runs west through farmed lowlands to the Ox Mountains. The farmed lowlands are broken by the attractive lakes and by limestone hills; they are mostly limestone-floored, covered with drumlins and drift which include some soils of considerable fertility, with good natural drainage. The farms are small, mainly about 30 ac. Both dairy and dry cattle are kept, but many beasts are sold young in the local fairs. In some areas there is daily milk sale to creameries.

Sligo was anciently MacDermott country. After the Anglo-Norman invasion it was dominated by the De Burgh (or De Burgo) power. With the murder in 1333 of the "Brown Earl," William de Burgh, earl of Ulster, the O'Connor Sligo became lord of the town and county under O'Donnell patronage and suzerainty, and the O'Dowds were established in the west. Donal O'Connor Sligo surrendered in 1567 the "captaincy" he had acquired by Irish custom over the territory and received from the queen a grant for life of the whole area. It was created a county in 1579. Forming part of Connaught, which was reserved by Cromwell for Irish proprietors, the district retained its Irish social pattern longer than most, though passing through the big changes brought about by the penal laws and the land acts.

In 1841 the county's population was 180,886. By 1956 it had fallen to 56,850, and in 1961 there was a further 6% decrease to 53,561. A county council meets at Sligo, but the county is joined with Leitrim under one county manager. Sligo, the county town and only urban district (pop. [1961] 13,145), has a mayor and corporation. It also has harbour commissioners. The county is joined with Leitrim to form one constituency which elects five members to the *Dail*. Sligo is the only town of any size in the county, the others being small market centres with fewer than 1,000 people. Ballymote (965) is the biggest market centre and in the Franciscan Friary (now in ruins) the Book of Ballymote was compiled in the 14th century; the book is now in the Royal Irish Academy at Dublin. There are mills at Ballysodare and Collooney and a shoe factory at Tobercurry.

See Terence O'Rorke, *History of Sligo: town and county*, 2 vol. (1889); W. G. Wood-Martin, *History of Sligo . . .*, 3 vol. (1882).
(T. W. Fr.; Hu. S.)

SLIGO (Sligeach) is a seaport and the county town of County Sligo, Republic of Ireland. Pop. (1961) 13,145. It lies on Sligo Bay and the River Garavogue between Lough Gill and the sea, 136 mi. (219 km.) NW of Dublin by road. The Roman Catholic Cathedral (1869–74) serves the diocese of Elphin, and there is also a Church of Ireland Cathedral. Summerhill College stands on a hill overlooking the town.

A castle, built in 1242 by Maurice Fitzgerald, lord of Offaly and justiciar of Ireland, was destroyed in 1270; it was rebuilt in 1310 but was again partly destroyed in 1369 and 1394. Maurice Fitzgerald also founded a Dominican friary (known as Sligo Abbey) in 1252. It was accidentally burned down in 1414 and later rebuilt, but was again destroyed in 1641 when the town was sacked. The ruins of the church consist of nave, choir, south transept, and central tower; and three sides of the cloisters have been preserved. Early in the reign of James I the town received a market and two annual fairs; in 1613 it was incorporated and received the privileges of a borough; and in 1621 it received a charter of the staple. In 1641 it was besieged by the parliamentary forces, but was afterward evacuated and occupied by the royalists until the termination of the war. In 1688 it declared in favour of James II and, after being captured by the Enniskilleners, was retaken (1689) by Gen. Patrick Sarsfield, but ultimately surrendered to the earl of Granard. The borough was disfranchised in 1870.

Sligo takes rank with Galway and Limerick as one of the three principal ports of the west coast of Ireland. Some cattle are exported, and coal, iron, timber, and provisions are imported. The harbour has commodious quays. Sligo is a centre of salmon fishing.

At Carrowmore, 3 mi. SW of the town, is a remarkably large collection of megalithic monuments—cairns, stone circles, and dolmens. On Knocknarea (1,078 ft. [329 m.]), west of Sligo, is a cairn which tradition sets down as the burial place of Queen Mab (Maeve of Connaught).

SLIM, SIR WILLIAM JOSEPH (1891–), British field marshal, best known for his work in the Burma campaign in World War II, was born in Bristol on Aug. 6, 1891, and educated at King Edward's School, Birmingham. In World War I he volunteered as a private, but within a few days became a commissioned officer. He saw active service in Belgium, France, Iraq, and the Dardanelles. In 1920 he was granted a regular commission and transferred to the Indian Army.

In 1940 Slim commanded the 10th infantry brigade of the famous 5th Indian division, which landed in northeast Africa and advanced into Eritrea. He was wounded, but recovered in time to lead the 10th Indian division in Iraq and in Iran, where he decisively defeated the enemy and made the first contact with the Russian Army at Teheran. For this service he was awarded the Distinguished Service Order. In 1942 he commanded the 1st Burma Corps and assisted in conducting an orderly retreat in Burma. Later, as commander in chief of the 14th Army, he inflicted a crushing defeat on the Japanese; after repulsing the enemy at Imphal and Kohima and capturing Mandalay, he drove the Japanese down the Irrawaddy River to Rangoon. In 1945 he became

commander in chief of Allied land forces in southeast Asia. In 1946 he was appointed commandant of the Imperial Defence College. He became chief of the Imperial General Staff in 1948 and was promoted to field marshal. In 1953 Slim was appointed governor general of Australia. In 1956 he published *Defeat Into Victory*, which gave a remarkable picture of the Burma campaign.

(E. B. Bn.)

SLIME MOLDS (Slime Fungi). Science fiction did not invent the slime molds, but it has borrowed from them in using the idea of sheets of liquid, flowing protoplasm, giant voracious amoebae, engulfing and dissolving every living thing they touch. What fiction could only imagine, nature has evolved, and only their sharp dependence on coolness, moisture and darkness has kept the slime molds from ordinary observation, for they are common enough.

Coolness, moisture and darkness are found in the soil and in logs, twigs and leaves decaying on the forest floor; there also are found the slime molds. An old log turned over—preferably a few days after a warm summer rain—may reveal on its underside a white or yellowish fan of almost liquid consistency, a sheet of slowly flowing protoplasm. The drier upper side of the log may be covered with what look like pinhead-sized toadstools that when touched give off clouds of dust-fine spores. The creeping, feeding fan, the plasmodium, or vegetative phase of a slime mold, has the characteristics of a primitive animal, a large terrestrial amoeba. The reproductive stage, or sporangium, with its dusty spores, has the characteristics of a lower plant, a mold. This double life is reflected in the equivocal scientific synonyms for slime molds, derived from the Greek: Myxomycetes, meaning "slime mold" or "slime fungi"; Myxomycophyta, the "-phyta" merely stressing the plantlike aspects; Mycetozoa, meaning "fungus animals." The last synonym was coined in 1858 by the great German botanist H. A. De Bary, when their dual role as plants and animals was elucidated.

The term slime mold embraces a heterogenous assemblage of organisms whose juxtaposition reflects a historic confusion between superficial resemblances and actual relationships. In this article the term Myxomycetes covers those forms with a plasmodial stage and definite fruiting bodies (true slime molds or

Mycetozoa in the strict sense); the term Acrasieae includes those forms in which individual amoebae aggregate without fusing to produce a fruiting structure (simpler slime molds, cellular slime molds); and the term Plasmodiophoreae covers a group of root parasites of higher plants having a plasmodial stage but lacking definite fruiting bodies. Other organisms, in most cases imperfectly known, have been included among the slime molds, but their treatment and placement are still uncertain.

TRUE SLIME MOLDS (MYXOMYCETES)

Sporangium.—Although some Myxomycetes form sporangia from plasmodia that creep over the surface of wood and leaves (*e.g.*, *Didymium*), others such as the common and beautiful *Stemonitis* and *Arcyria* form the fruits from plasmodia buried within the decaying wood. There is no indication that a log or tree stump is inhabited until some drops of creamy liquid appear on the surface—as if the dead wood were "sweating" drops of living protoplasm.

This is the first sign that the plasmodium, whose strands are thrown throughout the porous wood, is finishing its days as an active, growing, feeding network. These droplets coalesce and grow, expanding to a thick cushion that eventually becomes a column, perhaps half an inch wide and an inch high. A purplish tinge, gradually darkening to black, spreads over the column as it begins to take shape as a bundle of cylinders, each supported by the stalk that it has formed. The bundle, now almost black, dries out, and each sporangium, densely filled with dark spores, separates from its neighbours. The tenuous wall enclosing the sporangium, the peridium, disintegrates on drying. A touch of the hand or a puff of wind disperses the spores like smoke. Finally, only the delicate skeletons of the sporangia are left, each consisting of its stalk with an intricate network of branches, the capillitium, which held the spores. This whole feathery tuft of sporangia, resting on a silvery sheet of dried slime, the hypothallus, has formed and fulfilled its mission of reproduction within the span of a single day.

The startling transformation of a shapeless, ever-changing plasmodium into an intricately organized fruiting structure is the remarkable feature of the Myxomycetes. Not all follow the same pattern as exemplified by *Stemonitis*.

The capillitium of different species is formed variously, but a composite picture of its formation may be given as follows. Within the mass of protoplasm enclosed by the peridium, lines appear that later become chains of beads of clear droplets, or vacuoles.

The vacuoles coalesce to form hollow tubes whose walls become coated with dense material. Some capillitia are what the name implies, fine hairlike processes. Some have the walls beautifully sculptured with spirals and cogs, as in the genera *Trichia*, *Hemitrichia* and *Arcyria*, in which, on drying, the capillitium expands into a fluffy mass scattering the spores as it does so. In others the capillitium is permeated with lime.

Not all sporangia are stalked. Some are sessile, the plasmodium breaking up into droplets that invest themselves with a sporangial wall and complete the development without ever rising from the substrate. In the plasmodiocarps the plasmodium hardly breaks up at all, but the profound interior change of liquid protoplasm to dusty spores belies the exterior shape. The largest sporangia are

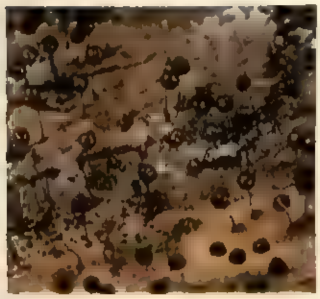
aethalia, compound sporan[illegible]gia composed of individual sporangia incompletely separated from each other. In the ubiquitous *Fuligo* and in *Brefeldia* they for[illegible] great cushiony masses, those of *Brefeldia maxima* sometimes [illegible]aching the remarkable length of one foot. The aethalia may [illegible]nge from the easily delineated individual sporangia of *Tubifera* thr[illegible]ugh the tortuous interwoven plasmodiocarps of *Ceratiomyxa* t[illegible] spherical fruit of *Lycogala*, in which individual sporangia are [illegible] reduced that the sphere is practically a single entity.

Although many invest[illegible]rs have recognized the potential research value of organism[illegible]t have the two aspects of growth—increase in mass and d[illegible]pment—separated in time, few have undertaken a study of [illegible]hysiology underlying morphogenesis. In 1938 W. D. Gray [illegible]ed that fruit formation of pigmented plasmodia occurred onl[illegible]en stimulated by light. Subsequent papers by a number of w[illegible]s have confirmed and extended these findings; for example [illegible] Fergus and R. D. Schein showed in 1963 that although no [illegible]res of *Physarum gyrosum* fruited in complete darkness, as li[illegible] one footcandle of light for 180 hours allowed fruiting, with [illegible]ime required for higher intensities. Since 1955 evidence ha[illegible]n accumulating that there is a more or less profound shift i[illegible]mount and in the type of metabolism as the plasmodium goes [illegible]ruiting.

Spores and Swarm C[illegible]s.—The spores are formed in the sporangium by successive [illegible]ing, or cleavage, of the protoplasm; these furrows redivide [illegible]s until each little block contains but one nucleus. Each blo[illegible]nds up, surrounds itself with a dense spore wall and shrinks [illegible]y from its fellows as it dries. The spores of Myxomycet[illegible]y vary slightly in shape from oval to round, and in size fr[illegible] $\frac{4}{1,000}$ to $\frac{15}{1,000}$ of a millimetre in diameter. The colour m[illegible]e black, gray, brown, brilliant red or yellow, rarely white [illegible] surface is often covered with ridges or spines.

If the spores are pla[illegible]n water, they swell, and in a half hour to a week, depending [illegible]es, and on factors such as age of the specimen, the spore w[illegible]her splits open or a pore is dissolved in it, and a minute, nak[illegible]ss of protoplasm slips out. This little globule, the swarm cell [illegible]ts out a whiplike process, a flagellum, becomes pear-shaped an[illegible]th the flagellum lashing in front of it, swims away. The swar[illegible]ll then may suddenly come to rest on any surface, put forth p[illegible]dopods and creep along. In this stage it can feed as any amoe[illegible]oes, by engulfing bacteria. The flagellum may be retracted and the myxamoeba is then practically indistinguishable from any o[illegible]e many species of small amoebae that teem in the soil. Or it m[illegible]y put forth its flagellum and suddenly take off, the myxamoeb[illegible] transforming again into the swarming stage.

This discussion has assumed thus far that the swarm cell is monoflagellate, and indeed one flagellum is all that is usually seen. However, in many species careful examination shows a shorter, second flagellum, pressed against the cell body and thus normally hidden from view. While such minutiae may appear unimportant, they provide clues that often indicate profound evolutionary relationships. The swarm cell is a sex cell, a gamete, which fuses with another swarm cell to initiate the plasmodium. In only relatively few species has this fusion been observed in the laboratory, even when germination is abundant, and in even fewer have plasmodia been grown successfully from spores.



ARTHUR L. COHEN

(LEFT) DELICATE FRUITING BODIES OF LAMPRODERMA IN THE ACT OF FORMING; (RIGHT) THE DARK MATURE SPORANGIA

Are the gametes alike (isogametes), so that any gamete may fuse with any other gamete, or are they of different types (heterogametes), so that what may be designated as a + gamete can fuse only with a − gamete? The discussion, particularly sharp in the 1930s, has been opened again and it appears that *Didymium iridis* is heterothallic (producing heterogametes) whereas *Fuligo cinerea* is homothallic (producing isogametes). It is possible that there are strain differences within the species, which would explain the flatly contradictory results of earlier workers, who, while working with the same species, may have been unknowingly comparing hetero- and homothallic strains.

Plasmodium.—In the primitive sexual act wherein two identical appearing swarmers fuse, the nuclei also fuse. The flagella are permanently retracted, and the amoeboid zygote (fertilized cell) begins to grow. Ordinarily when a cell has grown to a certain size it divides into two. The myxomycete zygote departs from this behaviour in that only the nucleus divides repeatedly: the cytoplasm, which remains together, becomes by definition a plasmodium, a multinucleate protoplasmic mass. As the plasmodium flows over the damp undersurface of logs or within the rotting wood itself, over leaves and, in some species, through the soil, it feeds on bacteria, molds and sometimes large fungi. What it cannot digest by engulfing, the plasmodium digests by enveloping with its slimy film.

On a smooth surface a vigorous plasmodium generally takes the form of a fan with trailing veins, creeping in the direction of the broadly curved front edge. Under the microscope the fan itself is like a broad delta, with a network of channels in which the protoplasm streams now slowly, now so rapidly that the particles are but blurred streaks. These channels gradually separate into distinct veins from front to rear. The streaming is not all in one direction. In any vein or channel, the protoplasm slows, pauses and then often reverses direction. Generally a little more flows toward the front than flows back, advancing like an incoming tide creeping up a beach.

While the description above is that of the "classical" plasmodium, other types have been observed. As classified by C. J. Alexopoulos in 1962 they are: the protoplasmodium—minute, sluggishly amoeboid, without distinct veins, each plasmodium giving rise to a single sporangium (example, *Echinostelium minutum*); the aphanoplasmodium—colourless, consisting of fine veins forming a network, or sometimes lying parallel to each other (the aphanoplasmodium, typical of some of the Stemonitales, lacks the fan structure described before; it is almost invisible and may be

of fairly frequent occurrence.); the phaneroplasmodium—with a fan, usually more or less opaque, often coloured; in other words the typical plasmodium. (To these the author would tentatively add a fourth type, a sluglike or limacine plasmodium, as in *Cribraria,* in which the plasmodia creep about like minute black slugs, apparently never forming a fan or network.)

If the plasmodium is jarred or cut, flow ceases and the protoplasm sets to a jelly; then hesitantly, but with increasing vigour, flow resumes. If a strand of a vigorous plasmodium is cut, a drop of the liquid protoplasm oozes out and usually immediately sets to a gel. This droplet, if gently detached and placed on a clean surface, may, in the course of a few hours, become a miniature plasmodium.

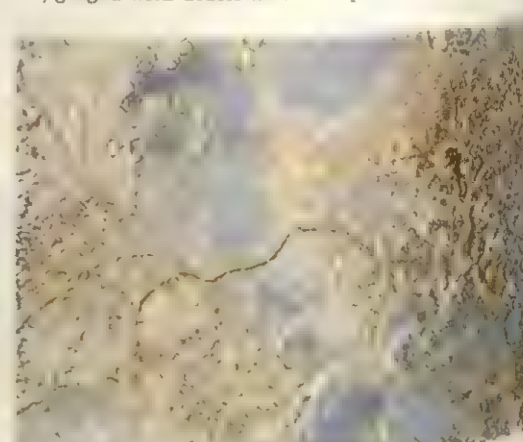
While many cells show this mysterious streaming of the liquid living substance, only the myxomycete plasmodium shows it on such a large scale. The theory has long been held that the streaming is due to contraction of the walls, which squeeze the inner liquid plasm from one part to another.

In an apparent confirmation of this muscular action of the more solid parts there has been isolated from the protoplasm of *Physarum polycephalum* a protein called myxomyosin, which resembles in its properties myosin, the contractile protein of vertebrate muscle. By 1962 choline esterase, an enzyme intimately concerned in the propagation of nerve impulses and in muscular contraction, was isolated from plasmodia of the same species. This finding is one more example of the essential biochemical unity of life—the molecular machinery that commands and drives the artist's hand is similar to that which sends the sheets and veins of myxomycete protoplasm pulsing through the disintegrating litter of the forest floor. In 1939 it was shown that a number of slime molds could thrive on laboratory media whose chief constituents were killed bacteria or yeasts, or extracts of microorganisms, although in nature slime molds presumably feed on living microorganisms as well as dead vegetable matter. While such a medium is [illegible] it is not completely known chemically. The next step [illegible] completed until the early 1960s, when J. W. Daniel, H. [illegible] h and their colleagues reported the continuous culture of [illegible] n of *Physarum polycephalum* plasmodia on completely [illegible] media. The medium for optimal growth contains a total of nearly forty constituents including minerals, amino acids and [illegible]. The majority of Myxomycetes have not been successfully cultivated in the laboratory at all; most of the rest have been [illegible] ted on complex vegetable media with other organisms pr[illegible] few have been kept in pure culture on similar media of unk[illegible] composition.

Oriented responses (tropisms) are [illegible] shown by plasmodia. Plasmodia will, as stated previously [illegible] creep off a stale substrate to a fresh one (chemotropism) [illegible] will move away from light (negative phototropism), except [illegible] they are preparing to fruit, in which case they seek the ne[illegible] posed region, probably attracted by light (positive phototrop[illegible]. The classical illustration of their behaviour is positive rhe[illegible] m—a plasmodium will creep upstream against gently flowin[illegible]

The pigments of most plasmodia [illegible] ntained in granules in an otherwise colourless protoplasm. [illegible] dia of different species may be rarely blue, black or green; [illegible] quently white, colourless, cream, maroon or brown; an[illegible] frequently yellow or orange. Colour often deepens with [illegible] d may be varied by a change in diet. Thus the plasmod[illegible] *Fuligo septica,* usually lemon-yellow in nature, may becom[illegible] on certain laboratory media and remain yellow on other[illegible] hese yellow and white plasmodia of the same parent source [illegible] nger fuse when brought into contact, but each can merge wit[illegible] plasmodium of its own colour. The same interesting phenom[illegible] n has been observed in other plasmodia, but if there is littl[illegible] our difference the independence of each is difficult to see a[illegible] ir veins cross in a confusing tangle.

The plasmodium is not an individual in the full sense. It behaves as a unit, but it can be cut into small pieces that may either fuse together again or grow into new plasmodia. The fluid and protean nature of the plasmodium was arrestingly shown by Lister's classical experiment in the late nineteenth century. A plasmodium, gorged with debris and food particles, was placed on



ARTHUR L. COHEN

(LEFT) PLASMODIUM OF FULIGO, WHICH HAS CREPT OUT OF A ROTTED WOOD CHIP; (RIGHT) ENLARGEMENT SHOWING THE DELICATE VEINLIKE CHARACTER OF THE FLOWING PLASMODIUM

moist cotton. It strained itself through the fibres, leaving the debris behind, and reconstituted itself, thoroughly scoured, on the other side of the barrier.

Sclerotium.—If a plasmodium is rapidly dried, it becomes a dull, lifeless, horny mass. But if it is given some time to dry, perhaps twenty-four hours, then it contracts, becomes somewhat waxy and usually retains its colour, having thereby transformed into a sclerotium. Under the microscope it can be seen that this sclerotium is composed of many cells, each containing a number of nuclei, with each cell separated from its neighbours by only the thinnest of walls. If the sclerotium is moistened, within a few hours the walls dissolve, and what earlier looked like a splash of dry, orange paint crawls off and resumes activity. Those plasmodia that form sclerotia easily may be filed away in envelopes for a year or more, to come alive again when dampened.

Habitat.—*Stemonitis, Lycogala, Tubifera, Ceratiomyxa* and a host of other genera are practically always found on wood, while many of the lime-bearing types, such as species of *Physarum, Mucilago* and *Badhamia,* are found on leaves and straw. *Physarum cinereum* typically lives in the soil, and sometimes its gray fruits and dark spores cover lawns overnight with a cindery, sooty film that just as quickly disappears with the next wind or rain. Only *Fuligo septica* can throw up its formless yellow or brown aethalia anywhere—on a tree trunk six feet above ground, in the crack of a concrete pavement, on desert sand and, as once recorded, on a whale's skull set to bleach on the grounds of the British Museum.

Classification and Relationships.—The Myxomycetes include approximately 60 genera and 500 species. The various orders, families, genera and species are distinguished from each other in rough order of importance by: spore colour, presence of a capillitium, presence of lime in the peridium or capillitium and size and detail of fruit and spore structure.

Confusion in the nomenclature reflects an earlier misunderstanding of the nature of the Myxomycetes. While it is true that the sporangia of such forms as *Lycogala* resemble puffballs, the differences in structures and the life cycles show that the primitive Myxomycetes and the advanced puffballs are entirely different. The myxomycete sporangium is formed from an undifferentiated, naked, fluid mass of protoplasm; the sporangia of the higher fungi are formed from the interwoven filaments, the characteristic hyphae. The myxomycete sporangium wall is a secretion around the spores; the fungal sporangium grows as a cell or mass of cells. Although some of the lower true fungi have motile swarm cells or gametes, these sooner or later transform into the typical hyphae, forming a feltlike vegetative structure, the mycelium. The myxomycete vegetative structure is the naked, amoeboid plasmodium.

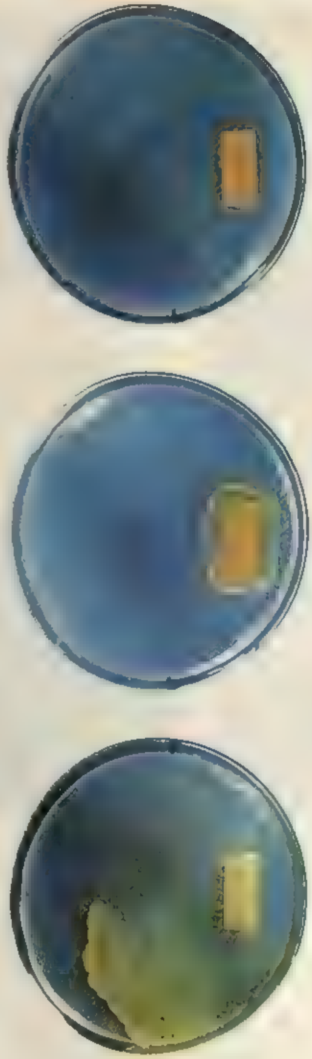
Classification of the Myxomycetes as plants or animals depends on whether the categorizer places more emphasis on the animal-like creeping, feeding plasmodia and myxamoebae, or whether he stresses more the funguslike fruiting body and the dry spores.

CELLULAR SLIME MOLDS (ACRASIEAE)

In 1869 Brefeld described a remarkable organism, *Dictyostelium mucoroides,* which to the naked eye looks very much like a common mold, a mass of spores set on a slender stalk. The basic structure and the mode of formation, however, are completely different from that of any mold, in fact, different from that of any other group of organisms known.

On a suitable substrate the spore germinates, and from the split spore case there emerges a small amoeba. For a time each amoeba feeds by engulfing bacteria, and then divides into two. These amoebae increase prodigiously in numbers under proper conditions and then begin to converge. Until this time of aggregation they are virtually indistinguishable from the many other amoebae that swarm in the soil.

If a plate of agar very dilute in nutrients is streaked with suitable bacteria such as the ordinary *Escherichia coli,* and a few of the spores of *D. mucoroides* are placed on the plate, the spores germinate, each yielding a very small amoeba. These amoebae feed on the bacteria, and divide again until the plate is practically divested of bacteria, the amoebae forming almost a complete covering. The amoebae then begin to congregate, climbing up on each other as they form a little mound. The centre pile becomes a hemisphere with a nipple, like half a lemon set on end, and in its interior a sheath forms around a core of amoebae each of which fills with a fluid, swells, secretes stiff cell walls, dies and becomes in structure and function a central pith. This cylinder of sacrificed amoebae forms the stalk on which the remaining amoebae climb. The stalk becomes narrower until finally it is a chain of single cells; the survivors of the ascension transform into oval spores, held in a drop of mucus.



ARTHUR L. COHEN

GERMINATING SCLEROTIUM OF BADHAMIA UTRICULARIS, PHOTOGRAPHED OVER A 9-HOUR PERIOD

Dormant orange sclerotium, daubed on a piece of absorbent paper and placed in a moist petri dish, within 4 hours (top) has absorbed water and begun to show activity; 1 hour later (centre) the fully active plasmodium has begun to spread out from the paper; (bottom) after 4 more hours the bulk of the plasmodium has left the paper and formed the typical veined plasmodium fan

In 1935 another species of *Dictyostelium* (*D. discoideum*) was described. This remarkable organism has one further stage of the welding of separate living entities into one composite organism. When the myxamoebae have aggregated to the conical stage with its little nipple at the top, the whole pyramid falls over on its side, and with the nipple (*papilla*) raised and leading the way, the "slug" crawls over the substrate toward the light before continuing further development.

It was found that if the myxamoebae were fed the brilliant red bacterium *Serratia marcescens,* they retained the indigestible pigment and formed pink aggregating and migration stages. When pieces of pink migrants were transferred to the normal white forms, they retained their identity. This knowledge was utilized in studying the simpler slime molds. If the papilla is cut off, the little slug ceases migrating at once; when a new papilla is grafted on, migration resumes. The discoid foot that gives the name to this species forms from the papilla; the mid-region forms the stalk and spores.

These little Acrasieae, repeating their life cycle in the laboratory, quickly, easily, dependably, without the vexatious errant ways of the Myxomycetes, have become popular experimental organisms for the study of morphogenesis.

Maurice Sussman and his co-workers have produced evidence that aggregation is started by "initiator" cells around which "responder" cells rally. The initiator amoebae, as seen in time-lapse cinemicrographs, are larger and more active than the more numerous responder cells. They are presumably the primary producers of an attractant called acrasin. In a series of experiments Sussman has demonstrated that mutant amoebae, whose lack of initiators allows them a chronic freedom, may be forced to aggregate by providing them with initiators from another source. The more initiators, the more fruits there are from a given number of amoebae.

Whether or not sexual reproduction exists in the Acrasieae has not been answered. Particularly in the late 1950s and the early 1960s there has been sharp written and oral discussion. The findings and arguments were judiciously reviewed in 1963 by L. S. Olive who finds no very convincing evidence in either direction.

ARTHUR L. COHEN

(LEFT) EMERGING RED PLASMODIUM OF TUBIFERA FERRUGINOSA: WITHIN HOURS THE RED WILL TURN TO UMBER AS THE PLASMODIUM MATURES; (ABOVE) COMPOUND FRUITING BODY OF FULIGO SEPTICA ON DEAD LOG; (BELOW) PLASMODIUM OF MUCILAGO SPONGIOSA ON BLADES OF GRASS

There are several different genera and species of Acrasieae, which differ strikingly in colour and shape. If the amoebae of these different forms are mixed, each sort separates itself out and forms its own fruiting structures. But what happens when they have started to aggregate? If the early aggregations, say, of the purple, branched *Polysphondylium violaceum* and of the white, single-stalked *Dictyostelium discoideum* are mixed, again the amoebae sort themselves out and build their own pure sporangia. If the aggregations have continued almost to the point of differentiation this sorting out no longer occurs; a hybrid fruiting structure is produced. But when the spores are sown, each produces amoebae after its own kind; the mixed decks unshuffle themselves.

The Acrasieae, first thought to be inhabitants of dung, are now known, with possible exceptions noted below, to be inhabitants of the soil. Isolation methods developed in the 1930–40s indicate that they are common, being numerous in species and numbers in forest soil, but also occurring in garden, lawn and field soils.

Despite the fact that the Acrasieae as a group can be carried through their life cycle much more easily than the Myxomycetes, knowledge of their nutritional requirements still lags behind that of the Myxomycetes. A number of species have been cultured on media containing killed microorganisms, and in 1963, H. Hohl and K. B. Raper reported the cultivation of two strains of *Polysphondylium pallidum* on an exceedingly complex medium similar to the one used for the culture of the myxomycete *Physarum polycephalum.*

Unlike the Myxomycetes, the Acrasieae consist of relatively few forms. The vast majority isolated from soil are species of either *Dictyostelium* or the closely related *Polysphondylium.* In 1884 P. E. L. van Tieghem described a remarkable organism consisting of stalks that supported a single row of spores rather than a spherical head, and which he called *Acrasis granulate,* after which the Acrasieae are named. The organism has apparently not been reisolated since that time, and the Acrasieae have gone without a type genus until 1960, when L. S. Olive and C. Stoianovitch reported the discovery of another species of *Acrasis, A. rosea.*

There are a few genera, such as *Guttulina* and *Guttulinopsis,* that fruit on dung of various animals, in which separation into stalk and spore head is highly imperfect, the spore cells and stalk cells shading into each other. It is tempting to construct an evolutionary scale from the probably accidental heaps of free-living soil amoebae through *Guttulina* and *Acrasis* and finally to *Dictyostelium* and *Polysphondylium,* each genus showing increased differentiation of cell types. But until more information is gleaned about these fascinating organisms, the lines of descent can only be suggested.

PLASMODIOPHOREAE

This group, all of which are root parasites of higher plants have only two economically important members, *Plasmodiophora brassicae,* the cause of club root of cabbage and related plants; and *Spongospora subterranea,* the agent of sweet potato powdery scab. Their relation to the Myxomycetes is indicated by the presence of flagellated swarm-spores that transform into myxamoebae and one, possibly two, plasmodial stages. They differ from the Myxomycetes in the absence of a well-developed sporangium with peridium, capillitium, etc., and in their strict dependence upon parasitic life.

No member of the Plasmodiophoreae has been carried indisputably through its life cycle in the laboratory, but a composite cycle may be made by piecing together the processes that have been observed. Upon the decay of the host tissue, spores are released into the soil and produce flagellate swarm cells, which invade root hairs and there transform into small plasmodia. By a complex process these plasmodia produce the gametes that fuse. The resulting amoeboid zygote penetrates the root itself, there to grow into a plasmodium that stimulates the characteristic tumourlike growth of the host cells. The plasmodia divide up into spores that are released on the death of the host tissues.

(A. L. Cn.)

SLING, an implement for propelling missiles, probably the earliest device by which force and range were given to the arm of a thrower. It consisted of a small strap or socket of leather

to which two cords were attached; the slinger held the ends of the cords in one hand, whirled the socket and missile rapidly round his head, and, loosing one cord sharply, dispatched the missile. In another type the sling was attached to a short staff that was held in both hands. This type was used for heavier missiles, especially in siege operations during the Middle Ages.

There are many references to slings and to slingers in the Bible; the left-handed slingers of Benjamin were famous (Judg. 20:16). Assyrian monuments show the sling of the ordinary type; slings were also used in the ancient Egyptian army, but not before the 8th century B.C. The sli[illegible] not mentioned in Homer; Herodotus (vii, 158) speaks of the s[illegible]gers in the army offered by Gelon to serve against the Persians. The sling seems to have been a weapon chiefly used by barbarian troops; the Acarnanians, however, were expert slingers (Thucydid[illegible] i, 81), and so also were the Achaeans, who later invented the s[illegible] that discharged a shaft with an iron bolt head (Livy xlii, 65, [illegible]m Polybius). In the Roman army by the time of the Punic W[illegible] the slingers (funditores) were auxiliaries from Greece, Syria [illegible] Africa. The Balearic islanders, who were in Hannibal's arm[illegible] were always famous as slingers. In medieval times the sling [illegible] much used in the Frankish army, especially in defending trenc[illegible] while the staff sling was used against fortifications in the 14t[illegible] century. Until the 17th century, slings were used to throw gre[illegible]

In modern times the w[illegible] has taken on other meanings. It denotes a hanging loop to support a wounded arm, a chain with hooks for raising or lowering he[illegible]y goods, or a shoulder strap for carrying a rifle or carbine. A variation of the ancient sling as a hand weapon is the slingshot, a [illegible]ked stick with an elastic band attached for hurling small pellets.

SLIPHER, VESTO MELVIN (1875–   ), U.S. astronomer whose discovery of the rotation and extraordinary space velocities of the spiral nebulae formed the first observational evidence for the expanding universe theory. He was born on a farm in Clinton County, Ind., Nov. 11, 1875, graduated from Indiana University, Bloomington [illegible] 1901, and received his Ph.D. degree there in 1909. For about [illegible]0 years he directed the Lowell Observatory at Flagstaff, Ariz., where he organized and guided the search which resulted in the di[illegible]very of the outermost planet, Pluto, predicted by the founder of the observatory, Percival Lowell.

Slipher made extensive investigations by methods of spectroscopy which resulted in the determination of the rotation periods of the planets; his discovery of molecular bands in the planetary spectrum ultimately led to the identification of their atmospheric composition. He demonstrated that many diffuse nebulae shine by the reflected light of the nearby stars. He also discovered the permanent sky and auroralike radiations of the night sky, their nocturnal intensity changes and the existence of interstellar sodium and calcium scattered throughout the depths of space.

(H. L. G.)

SLIPWAY, the waterfront space in a shipyard allotted to the building of a ship. It is fitted with foundations for keelblocks, shoring, and inclined launching ways, and with cranes, which may be of many types, for handling materials. When a gate or side walls are provided to exclude the water from the lower or outboard end of the slipway, it is sometimes called a semisubmerged slipway. The term slipway is also used for an inclined railway extending into the water and fitted with a cradle, on wheels or rollers, on which a vessel is hauled out for cleaning, painting, and repairs. Such a railway is usually called a marine railway in the United States and sometimes a patent slip in Great Britain.

A slipway should be distinguished from a slip, which is a space of water alongside a pier or wharf at which a ship may lie, as for loading or unloading.

A wet slip or wet basin in a shipyard is a berth alongside a pier, usually fitted with crane facilities, in which a vessel may lie afloat during completion after launching. (J. P. Ck.)

SLIVEN, a town and capital of the *okrug* of that name in eastern Bulgaria, lies in the southern foothills of the Balkan Mountains, 60 mi. (97 km.) W of Burgas. Pop. (1961 est.) 60,129. It was an old settlement which arose at a strategic point at the entrance of the Balkan passes. Later it developed as a manufacturing centre; the first woolen textile factory of Bulgaria was founded there in 1834. The town is now one of the chief centres of the textile industry, mainly woolen; other industries include woodworking and the manufacture of electric bulbs and silk and knitwear articles. Sliven is on the Sofia-Levskigrad-Burgas Railway. The town is associated with the Bulgarian revival of the 19th century, the movement for liberation from Ottoman rule.

Sliven *okrug* had a population (1963 est.) of 218,700, and an area of 1,388 sq.mi. (3,595 sq.km.). (An. Be.)

SLOAN, JOHN FRENCH (1871–1951), U.S. painter, the most brilliant of the artists associated with Robert Henri (*q.v.*), and a figure of some influence in U.S. art. Sloan was born in Lock Haven, Pa., on Aug. 2, 1871, and became a commercial newspaper artist in Philadelphia, where he studied with Henri. Eventually Henri and four of his associates went to New York (Sloan in 1904), and in 1908 these five, with three others ("The Eight"), held a group exhibition that was a significant forerunner of the modern art movement in the United States. Sloan's realistic paintings of urban scenes gave rise to the epithet "ashcan school," at first applied derisively to "The Eight" and subsequently in a more general and less pejorative sense to realistic modern artists generally. The Eight had little in common except their rejection of traditional and academic standards of the beautiful; they did not constitute a school of painting and had no further group exhibitions, but several of the artists, including Sloan, helped organize the Armory Show of 1913 in New York (*see* Painting: *United States*). For most of his life Sloan supported himself by illustrating, etching, and intermittent teaching; until the United States entered World War I he did illustrations for the socialist periodical *The Masses*. In 1939 he published *The Gist of Art*. He died in Hanover, N.H., on Sept. 7, 1951. His important paintings date from the period 1900–1920; representative examples are "Sunday, Women Drying Their Hair" (1912; Addison Gallery, Andover, Mass.); "McSorley's Bar" (1912; Detroit Institute of Arts); and "Backyards, Greenwich Village" (1914; Whitney Museum, New York).

See Lloyd Goodrich, *John Sloan* (1952); Van Wyck Brooks, *John Sloan* (1954); *John Sloan's New York Scene, from the Diaries, Notes and Correspondence 1906–1913*, ed. by Bruce St. John (1965).

SLOANE, SIR HANS (1660–1753), British physician whose collection of books, manuscripts, and curiosities formed the basis of the British Museum, was born on April 16, 1660, at Killyleagh in County Down, Ire. After studying medicine in London he traveled in France, taking his M.D. degree at the University of Orange in 1683. During a visit to Jamaica (1687–88) he collected about 800 new species of plants, of which he published an elaborate catalogue in Latin in 1696. Sloane was created a baronet in 1716, being the first medical practitioner to receive a hereditary title. He became first physician to George II and president of the Royal Society in 1727. His great stroke as a collector was to acquire the cabinet of William Courten (1642–1702), who had made collecting the business of his life. When Sloane retired from active work in 1741 his library and cabinet of curiosities had grown to be of unique value and on his death on Jan. 11, 1753, he bequeathed his collection to the nation, on condition that Parliament pay his executors £20,000. The bequest was accepted, and went to form the collection that was opened to the public as the British Museum in 1759.

SLOOP: *see* Boat.

SLOTH, a tree-dwelling mammal of proverbial sluggishness, belonging to the order Edentata (*q.v.*). The few extant species of sloths, forming the family Bradypodidae, of the infraorder Pilosa, or hairy edentates, are confined to the forests of tropical America; their extinct relatives, the ground sloths, once ranged into North America.

Sloths have rounded heads (which can be turned through an arc of 270°), inconspicuous ears, and grotesque, flattened faces. The body is about $2\frac{1}{2}$ ft. long; the forelimbs are longer than the hindlimbs, with long, curved claws sharp enough to inflict deep wounds. The three-toed sloth, or ai (*Bradypus*), has three toes on each limb; the two-toed sloth, or unau (*Choloepus*), has two on the forelimbs but three on the hindlimbs. Although most mam-

mals have seven neck vertebrae, the ai has nine and the unau has six or seven.

These most arboreal of mammals seldom voluntarily descend to the ground, but hang upside down from the branches and move with the greatest deliberation, hand over hand, through the trees, feeding on the vegetation. They are more active by day than by night. Although they can swim well, on the ground sloths can only drag themselves awkwardly along by their arms—making them easy prey for jaguars and other predators. They are almost invisible among the foliage, especially during the rainy season, when a green alga grows among their stiff hairs. Generally silent, sloths can utter a shrill cry.

They occur alone or in pairs. A single young, born at the beginning of the dry season, is carried clinging to the belly fur of the mother for about five weeks. In captivity the unau has lived more than 20 years; the ai, however, rarely survives more than a few months when taken from its habitat, partly because of its apparent dietary preference for *Cecropia* leaves. (L. H. M.)

SLOUGH, a municipal borough (1938) in the Eton and Slough parliamentary constituency of Buckinghamshire, Eng., lies 20 mi. (32 km.) W of London on the Great West Road. Pop. (1961) 80,781. It developed into an industrial centre after World War I, when an industrial park (the first in Britain and a model for many others) was established on the site of a wartime Army mechanical transport depot. It consequently became also a residential centre and is now the largest town in Buckinghamshire. It has over 300 factories and many housing developments. Among the notable buildings and many open spaces in the borough, the chief are the Norman church of St. Laurence, St. Mary's Church, Baylis House (*c.* 1695) and grounds, Salt Hill Pleasure Ground, Slough Lido, Herschel Park, and Upton Court Park. Slough is on the main Western Region railway and the London airport is 8 mi. SE.

(N. T. Be.)

SLOVAKIA (Slovensko), a region and former country of east-central Europe, from 1945 a component of the restored Czechoslovakia (*q.v.*). With an area (from 1947) of 18,922 sq.mi. (49,009 sq.km.), it is bounded north by Poland, east by the Ukrainian S.S.R., south by Hungary, west by Austria and by Moravia. The capital is Bratislava (*q.v.*).

The country was inhabited in the first centuries A.D. by Illyrian, by Celtic, and then by Germanic tribes. The Slovaks—Slavs closely akin to, but possibly distinct from, the Czechs—probably entered it from Silesia in the 6th or 7th century. For a time they were subject to the Avars, but in the 9th century the area between the Morava River and the central highlands formed part of Great Moravia, when the population accepted Christianity from Cyril and Methodius (*q.v.*). In the 890s, however, the German king Arnulf called in the Magyars to help him against Moravia. The Moravian state was destroyed in the first decade of the 10th century, and after a period of disorder Slovakia became one of the lands of the Hungarian crown in the 11th.

The main ethnic frontier between Magyars and Slovaks ran along the line where the foothills merge into the plain, though there were also Magyars settled in the larger valleys; later, the landlord class and much of the urban population in the whole area was Magyar. On the other hand, as the country suffered from chronic overpopulation, a constant stream of Slovak peasants moved down into the plains, where they usually were Magyarized in two or three generations. In the east, part of the mountain population was Ruthene (Ukrainian), and the mining areas of Spis had been colonized in the 12th century with German settlers, who founded flourishing cities.

In the 15th century Czech Hussites overran the country and for a time ruled parts of it, leaving behind them chiefly a cultural legacy. During the Reformation the German and Slovak converts adopted the Lutheran tenets, while the Magyars followed those of Calvin. The liturgical language used by the Slovak Protestants was Czech. The Counter-Reformation, however, was strongly pressed home in Slovakia by the Habsburgs, who succeeded to the Hungarian crown in 1526. When most of the Hungarian lands were occupied by the Turks, the Habsburgs retained possession of Slovakia.

Late in the 18th century a national renaissance began in Slovakia; it affected, of course, only a tiny fraction of this essentially peasant population. In 1803 an Institute of Slavonic Language and Literature was established at the Lutheran *lycée* of Bratislava: Juraj Palkovič (1769–1850) filled the first chair of Slavonic studies there. Two leading figures in the Slovak literary movement were Jan Kollař (1793–1852) and Pavel Josef Šafarik (1795–1861). Kollař, one of the earliest Pan-Slav enthusiasts, regarded the Slovak as indistinguishable from the Czech language, while Šafarik revered Slovak only as a [illegible] literary form. Other leading Slovaks of this period were eager defenders of a Slovak language and nationality separate from those of the Czechs. Ljudevít Štúr (1815–56), the successor of Palkovič in Bratislava, was expelled by the Magyars in 1844. It was after this that he adopted the dialect of central Slovakia as the best literary form of Slovak if any form of the Slovak language was to be defended against Magyar pressure. Štúr became the foremost leader of the Slovaks in 1848 when, after his literary "separatism," he entered after all into the closest alliance with the Czechs, especially with Karel Havliček. He and Šafarik were active members of the Pan-Slav Congress in Prague. (*See* Bohemia.)

During the period of Austrian absolutism after the suppression of the Hungarian revolution in 1849 Slovakia was for several years *de facto* separated from the rest of Hungary under a regime which favoured the non-Magyars. After the Austro-Hungarian *Ausgleich* or Compromise of 1867 the Hungarian government reversed this trend and pressed Magyarization forward. Secondary education in Slovak was entirely suppressed; between 1869 and 1911 the Slovak primary schools were reduced from 1,921 to 440 in number; and the schools law of 1907, associated with the name of Count Albert Apponyi, established Magyar control over the confessional schools, which were supported solely by Slovak voluntary contributions. Though the electoral system was heavily weighted against non-Magyars and the Hungarian police made difficulties for their supporters, a few Slovak deputies sat in the Hungarian Parliament; on the eve of World War I one of these was Milan Hodža. Meanwhile the difficulties which they encountered in Hungary, the poverty and suppression by comparison with which the Czechs under Austrian rule were thoroughly well-off, drove large numbers of Slovaks to emigrate, particularly to America. (*See* Czechoslovakia: *History*.)

Only on May 24, 1918, was it possible for the Slovaks in Hungary to declare openly for participation in a future state embracing Slovakia and the Czech lands. On May 30, the American Czechs and Slovaks concluded on agreement at Pittsburgh, to which T. G. Masaryk (*q.v.*) subscribed. On Oct. 30, at Turčiansky Svaty Martin, the Slovak National Council repeated the declaration of May 24; and on the same evening Hodža arrived from Budapest with the news of the collapse of the Hungarian regime with which he had been negotiating. He then persuaded the Slovaks to drop a demand for separate representation at the Peace Conference. Three Slovaks, namely Hodža, Vavro Šrobar and Milan Ivanka, became members of the first Czechoslovak government, headed by Karel Kramař: Šrobar was appointed minister for Slovakia. The peace settlement drew the frontiers of Czechoslovakia so generously as to leave a large Magyar minority in southern Slovakia.

Release from Magyar oppression gave the Slovaks leisure to develop irritation against the Czechs, whose regime proved more centralist than the Pittsburgh agreement had led the Slovaks to expect. However, the Prague government at any rate supplied the Slovaks with educational facilities: the first Slovak university was opened at Bratislava in 1919.

On Oct. 6, 1938, after the Conference of Munich (*q.v.*), the Slovaks declared themselves autonomous within a federal Czecho-Slovak state. The Slovak autonomist leader, Andrej Hlinka (*q.v.*), had died in the previous August; his heir was Josef Tiso, who now became prime minister. On Nov. 2, by the first Vienna award Germany and Italy compelled Tiso to surrender the southern rim of Slovakia, with the major part of the Magyar minority, to Hungary. After the German occupation of Prague, Slovakia on March 18, 1939, became a nominally independent state under

German protection; and in October, when World War II had broken out, Tiso was chosen to be president of Slovakia, with Bela Tuka as premier. For the next five years the Slovak regime was characterized by the balance preserved between the cautious clerical Fascism of Tiso and the more Nazi policy of Tuka and his friends, but the balance tilted increasingly in Tiso's favour. At first German protection brought Slovakia unprecedented prosperity. But the Slovaks sympathized with the Poles, against whom Hitler forced them to declare war; and later they resented having to send a contingent to fight against the Russians in the U.S.S.R. After the Battle of Stalingrad, Slovak sentiments became confused, and by August 1944 there was enough opposition to bring about a serious rising against the Germans, which lasted for two months.

With the arrival of the Soviet and Czechoslovak armies early in 1945, the Slovak National Council declared for the government of Edvard Beneš (*q.v.*), while claiming the complete equality of the Slovaks with the Czechs. The frontier of 1919 with Hungary was restored, with a small extension south of Bratislava. Some of the Magyars of the recovered territory were expelled.

After the Communist seizure of power in Czechoslovakia in February 1948, Slovakia was more severely subjected to Prague. On July 31, 1956, however, a new constitutional law made the Slovak National Council (counterpart of the Czechoslovak National Assembly) the organ of state power in Slovakia, while its former legislative powers were increased. The National Council received the right to nominate and recall the Board of Commissioners (counterpart of the Czechoslovak Council of Ministers), which was to have full executive and administrative powers in Slovakia, except for national defense, foreign affairs, foreign trade, and some branches of heavy industry and of rail transport.

The Communist regime made special efforts to speed up the industrialization of Slovakia. By 1956 the industrial output was 5.3 times greater than in 1937 (this increase was begun under German protection during World War II). Periodically, nevertheless, there were indications of the persistence of the old separatism.

In July 1960 Slovakia was subdivided into three administrative regions: West Slovak (chief town Bratislava), Central Slovak (chief town Banská Bystrica) and East Slovak (chief town Košice).

SLOVAK LANGUAGE. Slovak became in 1918 the official language of the eastern part of Czechoslovakia. In 1955 the estimated number of speakers of Slovak in Europe was about 3,500,000, and nearly 500,000 Slovaks in the U.S. continued to use their native tongue to some extent.

The Slovaks were under Hungarian rule from the 10th century until 1918, and for centuries there was no serious attempt to write Slovak. The flourishing Czech culture of the 14th and 15th centuries produced a written language which differed from most Slovak dialects little more than these dialects differed among themselves. By the 16th century a number of Slovak towns were keeping their records in Czech.

An attempt in the 1780s to raise the western Slovak dialects to the position of a literary language aroused little interest. In the 1840s a group led by L'udevít Štúr (1815–56) began to write in the central Slovak dialects. Štúr's language, as modified and codified by M. Hattala in 1852, rapidly gained approval and was accepted as standard. (*See* further CZECHOSLOVAK LITERATURE: *Slovak Literature*.)

Classification.—The contemporary literary Slovak and Czech languages differ in so many points of detail that even the shortest utterance can be identified as either Czech or Slovak (*see* also CZECH LANGUAGE). During the 1920s the official designation of both languages was Czechoslovak, but because of the striking and pervasive differences the term was abandoned. On the other hand, the over-all agreement in vocabulary, in word formation, and in syntax reveal such a close relationship between the two that the linguist is justified in speaking of a Czechoslovak subgroup of the West Slavic languages (*see* SLAVIC LANGUAGES).

The spoken Slovak dialects, as opposed to the standardized language of culture and state, fall into three major groups. The central one is the most distinctive type, and possesses certain features in common with South Slavic. Eastern and Western Slovak are closer to each other than to the central dialects. Nowhere, however, is there a sharp linguistic frontier, for every local type of speech may be viewed as a transition dialect between the neighbours on every side. Eastern Slovak has certain affinities with Polish (loss of long vowels, some consonantal features), but it passes into the typical Slovak of central Slovakia, which in turn is transitional to the Western Slovak dialects that shade into the Czech Moravian dialects and on to the typical Czech of Bohemia. The dialects are all mutually comprehensible, except perhaps the extreme Eastern Slovak and Bohemian Czech.

Characteristics.—Like Czech, Slovak has a system of long and short vowels and an automatic, nondistinctive stress which always falls on the first syllable of a word. The two vowel systems were doubtless almost identical in the early Middle Ages, but since the 14th century Czech has undergone far-reaching changes, while Slovak has been much more conservative. Slovak has retained long syllabic *l* and *r*, and a series of diphthongs (*ie, iu, ia, uo*). It possesses the open front vowel *ä* (*päť* "five," *mäso* "meat"; Cz. *pět, maso*). In the consonantal system, Slovak did not develop the distinctive sibilant vibrant *ř* of Czech, but did retain the soft *l'* (*strieľať* "to shoot"; Cz. *střileti*). It developed *dz* and *dž* as independent phonemes. In morphology, Slovak has suppressed certain consonantal alternations: *e.g.*, *veľký* "big," pl. *veľki* (Cz. *velci*); *ruka* "hand," dative *ruke* (Cz. *ruce*); *platim* "I pay," *platený* "paid" (Cz. *placený*). The first person singular of all verbs ends in *m*. The vocative has been lost except in a few words.

(H. G. L.)

SLOVENE LANGUAGE, a member of the South Slavic group of the Slavic languages (*q.v.*), is one of the state languages of Yugoslavia. It was spoken in 1955 by about 1,500,000 people in the northwestern corner of Yugoslavia and neighbouring areas in Austria and Italy, and by some of the 180,000 Slovenes in the U.S.

History.—The earliest record of Slovene is generally agreed to be found in the Freising manuscript, from about A.D. 1000, which contains a confessional form, a short homily, and a confessional prayer. After that the Slovenes, subject to the Austrians, did not write their own language until the Reformation, when a group of Protestants, led by Primož Trubar, translated some of the Scriptures and wrote tracts. Their religious works were destroyed early in the 17th century, during the Counter-Reformation, but their grammatical and orthographical usage served as a model for the few Catholics who wrote Slovene during the next 200 years. The Enlightenment brought a new interest in Slovene, and at the end of the 18th century a Slovene translation of the Bible appeared, followed quickly by grammars (by Jernej Kopitar in 1808 and by Valentin Vodnik in 1811), dictionaries, and literature of all sorts. By the middle of the 19th century a standard written language was in use. (*See* YUGOSLAV LITERATURE.)

The agreement on matters of orthography and on the words and grammatical forms suitable for literature was not accompanied by an agreement on standard pronunciation. More than a century of discussion culminated in an authoritative handbook of orthography and pronunciation (1950) that was reissued in drastically revised form (1962). Yet great diversity of pronunciation persisted, apparently little affected by the unifying influences of the schools, radio and television, and modern transportation.

The reason for the lack of agreement lies in the extraordinary diversity of Slovene dialects, which developed during a millen-

nium when the Slovenes had no major administrative or economic centres, no unifying political organization, and lived in scattered communities with little communication between one another. The Alpine villages in the north and west were particularly isolated, and the multiplicity of dialects is correspondingly greater there. The leading Slovene authority, Fran Ramovš, distinguished seven dialect groups, with no fewer than 46 individual dialects. While there are significant differences in consonantism, morphology, and vocabulary, it is the vowels and the accent which vary most widely. Slovenes tend to pronounce the literary language with the vowels of their own local dialect when speaking formally, and in informal conversation they often add dialect grammatical forms as well.

Slovene is closely related to its eastern neighbour, the Serbo-Croatian language (*q.v.*), and the transition from eastern Slovenian dialects to the *kaj* Serbo-Croatian of Croatia is gradual. Practically speaking, however, the two standard languages are more remote. Slovenes have some Serbo-Croatian in school and understand it at least passively, but the average Serb or Croat, without special preparation, can read Slovene only with great difficulty and understands little or nothing of the spoken language.

Phonology.—The recommended pronunciation is a compromise between that of the Lower Carniola dialect group (*dolenjski*), which covers the largest area, and the Upper Carniola group (*gorenjski*), which includes the dialect of Ljubljana, the capital of Slovenia. It distinguishes seven long vowels (*i, ẹ, e, a, o, ọ, u*) plus syllabic *r*, occurring only under stress, with either rising or falling intonation, and six short vowels (*i, e, a, o, u, ə*) plus syllabic *r* which may be stressed or unstressed. If there is a long vowel in a word, it must be stressed; otherwise the stress falls on the last syllable. It is a very strong stress; unstressed vowels tend to be reduced, and some of them disappear altogether in the pronunciation of many speakers. Normal spelling, utilizing only the five letters *i, e, a, o, u,* unfortunately gives little help in pronunciation of vowels.

Slovene is characterized by the development of Common Slavic $ǫ > o$, of both *ŭ* and *ĭ* to *a* in long and *ə* in short syllables, $tj > č$, $dj > j$, syllabic $l > ou̯$ (spelled *ol*), soft $r > rj$, and a general tendency for long vowels to be closed, short vowels open. None of these features is unique among the Slavic languages, but they occur together only in Slovene.

Other Features.—In grammar, Slovene has preserved the dual in nouns and verbs, and the supine is usually distinct from the infinitive. The vocative has been lost. The future for both aspects is periphrastic: *bom* (< **bǫdǫ*) + *l*-participle; *e.g., bom kupil/kupoval,* "I shall buy/be buying." The vocabulary includes many borrowings from German, while Czech and Serbo-Croatian models have been important in creating modern technical terminology.

SLOVENIA (SLOVENIJA), a country of southeastern Europe, politically organized in 1946 as one of the six people's republics of Yugoslavia (*q.v.*). Bounded west by Italy, north by Austria, northeast by Hungary, and southeast by Croatia, it has an area of 7,819 sq.mi. (20,251 sq.km.). Of the population, 95% are Slovenes, a South Slav race with its own language.

Geography.—Slovenia is largely mountainous and wooded, with deep and fertile valleys and numerous rivers. Its northwestern tip reaches into the Julian Alps, where Mount Triglav towers over a region of great natural beauty. From this region the Sava River flows southeastward and on its banks are the steel town of Jesenice and the textile centre of Kranj. It bypasses Ljubljana (*q.v.*), the capital of the republic, and then cuts a gorge through the hilly country of the coalmining towns of Trbovlje, Zagorje, and Hrastnik.

The Karavanke (Karawanken) Mountains stand on the Austrian border. Farther to the south and southeast the Kamnik mountain group emerges. Along the Drava River the country descends into the hilly region of Pohorje and Kozjak. Maribor (*q.v.*), on the Drava, is the second largest town of Slovenia. The ancient town of Ptuj, further down the Drava, has aluminum works in its neighbourhood. Eastward the hills yield to the fertile Pannonian plain, where oil is extracted.

Slovenia between the Mura, Drava, Savinja, and Sava rivers is a good wine-growing region and is also noted for mineral springs. Celje is a major town in this region.

West and southwest from Ljubljana, along the precipitous course of the Soča River (It. Isonzo), the climate and the general character of the country become less continental and more Mediterranean. Southwest from Idrija, where mercury is mined, a limestone plateau eventually leads to a strip of seacoast south of Trieste.

History.—The Slovenes arrived in their present territory and farther north in the 6th century A.D. Subjected to Bavarian domination *c.* 743, they were subsequently incorporated into the Frankish Empire of the Carolingians. With the partitioning of that empire in the 9th century, the country was assigned to the German kingdom. It was eventually divided between the marks or marches of Carantania (Carinthia), Carniola, and Styria. The Germans reduced the Slovenes to serfdom, and most of the Slovene settlements north of the Drava were germanized. That the Slovenes preserved their identity through centuries of German rule was largely due to intensive educational work by the native intelligentsia, most of whom were Roman Catholic priests. The suzerainty of the Habsburgs (*q.v.*) over the Slovenian lands was gradually established from the last quarter of the 13th century onward. The counts of Cilli (Celje), powerful in the Middle Ages, died out in 1456.

Sporadic risings of peasants in the 15th and 16th centuries were exceptions in an uneventful history. One of these risings (1573), made in alliance with Croatian peasants led by Matija Gubec, had political and nationalist undertones, but most were motivated entirely by social and economic grievances. The reforms decreed by the empress Maria Theresa and by her son Joseph II in the 18th century improved the lot of the peasantry.

From 1809 to 1814 a large part of the Slovene territory was included in the Illyrian provinces of Napoleon I's French Empire, and the French encouraged local initiative and favoured the use of Slovene as an official language. After Napoleon's defeat, Habsburg rule was restored. In 1848 the first Slovene national program was formulated; it demanded a unified Slovene province within the Austrian Empire. Hopes for a political union of South Slavs (Slovenes, Serbs, and Croats) were expressed in the 1870s. Political parties—the Slovene People's Party (Catholic), the Progressive (Liberal) Party, and the Socialist Party—were formed in the 1890s. Members of the Catholic clergy also established large-scale cooperative movements among peasants and artisans.

On May 30, 1917, during World War I, the Slovene and other South Slav deputies in the Austrian *Reichsrat* put forward their declaration in favour of "the unification of all territories of the monarchy inhabited by South Slavs in one independent political body, under the sceptre of the Habsburg dynasty"; but in 1918 the Slovene political leaders, on a wave of popular enthusiasm collaborated in the formation of the Kingdom of Serbs, Croats, and Slovenes (*see* YUGOSLAVIA). At the Paris peace conference, however, the Allies awarded Gorizia (Gorica) and adjacent territory, with a Slovene population of about 300,000, to Italy. Moreover, the Treaty of Saint-Germain (*q.v.*), between the Allies and Austria, assigned only a small part of southern Carinthia outright to Yugoslavia. For the rest of southern Carinthia it was decided to hold a plebiscite, in two zones; but since on Oct. 10, 1920, the more southern zone chose Austria, no plebiscite was held in the northern zone (Klagenfurt). Both zones were thus left to Austria.

There was some resentment in Slovenia at Serbian hegemony in Yugoslavia before World War II, though gratitude was felt for progress made in the economic and educational fields (the first

Slovene university was established in Ljubljana).

In World War II Slovenia was partitioned: Italy took the southwest, with Ljubljana; Germany took the northeast, with Maribor; and Hungary recovered the Prekomurje (a small area north of the Mura attached to Slovenia in 1920). Slovene resistance movements sprang up, by far the most significant being the Communist-led Liberation Front. Yet Communist partisans combined activities against the invaders with a ruthless struggle against other potential opponents, particularly members of the former Slovene People's Party. Anti-Communist military units were subsequently organized under the auspices of the occupation authorities.

After the Allied victory of 1945 the old Slovenia returned to Yugoslavia. Under the Paris peace treaty of 1947, Italy ceded additional territory in the west (but not Gorizia); and in 1954 some of the former Free Territory of Trieste (*q.v.*) was annexed. The federal constitution of Yugoslavia (1946) made Slovenia an autonomous republic with its own People's Assembly as the supreme organ of power. The assembly consisted of two houses: the Republican Council (elected on a general ballot) and the Council of Producers (elected by workers and salaried staff of Slovenia's industries). The assembly appointed an Executive Council. Though these constitutional arrangements were circumscribed in practice by the dictatorship of the Yugoslav League of Communists, Slovenia enjoyed a fair degree of independence in the economic and cultural field. For administrative purposes Slovenia was divided into 8 districts and 83 municipalities.

SLOWACKI, JULIUSZ (1809–1849), ranks with Adam Mickiewicz and Zygmunt Krasinski in Poland's triad of Romantic messianic poets (*see* POLISH LITERATURE: *Romanticism*). Born at Krzemienec on Aug. 23 (old style; Sept. 4, new style), 1809, he was educated at Wilno (now Vilnius, Lith.), at the *Gymnasium*, and (1825–28) at the university. In 1829 he entered the civil service in Warsaw but, after the failure of the November revolution, resigned and went to Dresden, and thence (July 1831) to London and Paris with dispatches from the insurrectionary government. During 1833–35, he was in Switzerland and, in 1836, in Italy, where he wrote the love idyll *W Szwajcarii* (1839; Eng. trans. *In Switzerland*, 1953). His travels in the Middle East (1837–38) are described in *Podróż na Wschód (Podróż do Ziemi Świętej*; "Voyage to the Holy Land"; publ. 1866), a narrative poem in the manner of Byron's *Childe Harold*.

Supremely egocentric, Slowacki has been called "a poetic peacock," "the most romantic of all the Romantics." Rivaling Mickiewicz's *Dziady III* and *Books of the Polish Nation and Its Pilgrimage*, in *Kordian* (1834), a romantic drama, and in *Anhelli* (1838; Eng. trans. 1930), a poem in prose, he scanned the recent past and the present, finding in a projection of his own self the promise of Poland's delivery. His palingenetic view of history, formed c. 1844, was to have found expression in the uncompleted visionary poem *Król Duch* ("King Spirit"; part publ. 1847; full text, 1925).

As a dramatist he provided the Polish theatre with a variety of plays (some published posthumously in 1866), largely inspired by Shakespeare (*Balladyna*, written 1834), classical drama (*Lilla Weneda*, 1840), Calderón (*Ksiądz Marek*, written 1843; *Sen srebrny Salomei*, 1844), and by contemporary productions seen in Paris. *Fantazy* (written 1843) is an anti-Romantic comedy. These constituted a repertoire of serious drama equal in merit to that of western Europe and still preeminent in Poland. His dramatic work was the chief native influence on Stanislaw Wyspianski (*q.v.*).

Slowacki was master of a wealth of verse forms traditional as well as adopted, but excelled in conveying his own feelings in lyrics and in lyrical or polemical digressions, such as those in *Beniowski* (written and part publ. 1841; full text, 1866), a verse narrative indebted for its framework to Ariosto and to Byron's *Don Juan*. His technical virtuosity, the richness and inventiveness of his vocabulary, and the evocative nature of his imagery made him a precursor of the Symbolists. The poets of the "Young Poland" movement and after acknowledged him as their master.

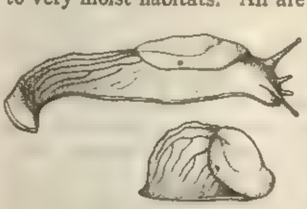
SLUG, any snail with the shell reduced to an internal plate, a series of granules or completely absent. Generally the term refers to a land mollusk, but members of the marine order Nudibranchia are called sea slugs.

Ranging in size from ½ in. to more than 6 in., slugs are restricted to very moist habitats. All are usually active only at night or on overcast days. Eggs are buried in the soil, and the animals live one to four years. All species are both male and female, some with one, others with two genital pores. Most slugs have the respiratory and excretory ducts combined into a single external opening. Usually slugs are mottled with brown, gray, green or buff, but some species have brilliant markings of orange, red, purple or yellow.



COMMON SLUG: (ABOVE) IN CRAWLING POSITION, (BELOW) INACTIVE

The approximately 300 species of land slugs are not closely related, since loss of an external shell happened several times during snail evolution. The common slugs (families Arionidae, Limacidae and Philomycidae) of temperate-zone fields, forests, gardens and greenhouses feed on fungi, decaying plants and occasionally the leaves of living plants. Often a nuisance in gardens and greenhouses, they can be controlled by spreading ashes or a bait composed of bran and metaldehyde (30 to 1). The tropics have a few European species introduced by man, and the very primitive plant-eating Veronicellidae. Other vegetarian slugs include the relict Athoracophoridae of Melanesia, Australia and New Zealand and the intertidal pulmonates of the family Oncidiidae. Slugs which feed on other snails or earthworms include the European Testacellidae, South African Aperidae and Malayan-Indonesian Rathouisiidae.

The sea slugs (nudibranchs) live in shallow reef waters, sand flats or rocky pools where they browse on minute algae. Delicately coloured and often translucent, they are among the most beautiful sea creatures. Retiring in habit, they are seldom seen.

See SNAIL; GASTROPODA. (G. A. S.)

SLUIS (SLUYS), **BATTLE OF,** a naval engagement of the Hundred Years' War fought on June 24, 1340, which ended in an overwhelming defeat of the French fleet by English forces under the command of King Edward III. Sluis, now in the Zeeland province of the Netherlands, was in the 14th century a flourishing port on the estuary of the Zwyn River (now silted up) in northern Flanders, and the encounter took place in the mouth of the estuary below Sluis. After four months in England, Edward was returning to Flanders to resume his campaign against France. He had intended to cross with a modest force, but, warned that the French naval commanders, Hugues Quiéret and Nicolas Béhuchet, were waiting to prevent his landing, he hastily impressed more ships and soldiers. Edward sailed from Orwell, Suffolk, on June 22, and was joined at sea by Robert, Lord Morley, admiral of the northern fleet. The English force may have comprised about 147 ships (*Chronicle of Lanercost*), but the number of soldiers on board is unknown. It is possible that Edward also received some Flemish support during the battle, but this is uncertain. The French, with a fleet of about 200 ships manned by over 20,000 soldiers and sailors, had a numerical advantage, but this was wasted through the unwise decision to fight from a defensive position within the estuary.

Shortly after midday on June 24, with the wind in their favour and the sun behind them, the English sailed in on the French fleet, which was massed in three tight lines. The fire of the English archers was fierce and accurate, and when the ships met, fighting with sword, lance, and axe began. A bitter struggle followed, which lasted into the night. By the following morning all except 24 enemy ships had been captured or sunk, and French loss of life had been great. The scanty evidence about English losses tends to confirm Edward III's claim that they were comparatively small. This victory seriously weakened the naval resources of France, and added greatly to Edward III's military prestige. The battle secured for England a temporary ascendancy at sea, but not, as has often been claimed, a command of the Channel which lasted for many years. *See* also HUNDRED YEARS' WAR.

See Sir N. H. Nicolas, *History of the Royal Navy*, vol. ii (1847); C. Bourel de la Roncière, *Histoire de la Marine Française*, vol. i (1898). (J. W. SE.)

SLUM: *see* HOUSING.

SLUPSK (German STOLP), a town of northern Poland in Koszalin *wojewodztwo* (province) and a district capital. Pop. (1960) 53,000. It lies in the coastal plain on the Slupia River, 11 mi. (18 km.) from the Baltic. About 35% of the town was destroyed during fighting in World War II, the old buildings suffering most. There are many factories; one of the largest in all Poland produces furniture for export. The town is on the Gdynia-Szczecin Railway, with a branch northward to Ustka on the coast.

A fortress was erected at Slupsk in the 8th and 9th centuries, which came under Poland at the end of the 10th century with the rest of Pomorze (Pomerania). After a short period of independence under its own duke, it shared the fate in the 11th–13th centuries first of Danzig Pomorze, then of Western Pomorze. In 1648 Slupsk and the rest of the dukedom was seized by Brandenburg. It was returned to Poland in 1945. (T. K. W.)

SLUTER, CLAUS (*c.* 1350–1406), the greatest sculptor of his time, was probably born at Haarlem in Holland. He entered the Brussels stonemasons' guild about 1380, and in 1385 was employed in the workshop of Jean de Marville, chief sculptor to Philip the Bold, duke of Burgundy. On Marville's death in 1389, Sluter succeeded to his position and to two major works then in progress, the portal of the ducal chapel at the Chartreuse de Champmol, Dijon (*q.v.*), and the duke's tomb, which was to be installed in the same building. In 1392 he visited Paris, and in 1393 Mehun-sur-Yèvre, where he inspected the works executed for Jean, duc de Berry, by André Beauneveu. In 1395 the duke of Burgundy commissioned a monumental Crucifixion group to crown a well (the *Puits de Moïse* or "Well of Moses") in the cloister of the Chartreuse. On Sluter's death, the direction of the workshop passed to his nephew and pupil, Claus de Werve.

GIRAUDON

DETAIL OF AN ANGEL FROM THE "WELL OF MOSES" BY CLAUS SLUTER. IN THE DIJON MUSEUM, FRANCE

The three works mentioned above still exist, albeit in damaged condition. The tomb (Dijon Museum) has suffered severely and the effigy of the duke is a 19th-century replacement. The substructure, an open arcaded gallery along which passes a numerous procession of diminutive mourners, is an ingenious and original conception which is probably due to Marville. Two of these mourners were in existence in 1404 and others may have been completed by Sluter before his death; the best of them, despite their small scale, exhibit a masterly breadth and realism. The tomb was not finished, however, until 1410 and many of the figures were doubtless made under Werve's direction.

The life-size statues of the Chartreuse portal (complete by 1397) comprise the Virgin and Child (sometimes attributed to Marville) on the central pillar of the doorway and, on either side figures of the duke and duchess (the latter finished by 1393) protected respectively by St. John the Baptist and St. Catherine (both finished by 1391). The imposing physical presence and intense psychological interaction of these figures seem almost to annihilate their architectural frame. The celestial personages hover in a swirl of near-Baroque drapery; the ducal pair are living portraiture, reverend and grave. The Calvary group has been reduced to a battered torso of Christ and a base surrounded by six life-size prophets (executed 1400–05), which rank among the greatest masterpieces of European sculpture. Transcendental beings swathed in endless convolutions of Gothic drapery, they are at the same time living persons whose presence asserts itself like a physical shock. The sculptor's chisel, minutely exploring the wrinkles of ancient flesh, has drawn a map of the soul unparalleled in art, except in the late portraits of Rembrandt.

Sluter's work represents the culmination of a tradition—that of the Franco-Flemish realist sculpture whose older masters were Jean Pepin of Huy and Jean de Liège—but his genius was intensely personal. Both the painting and sculpture of northern Europe would have worn a different aspect in the 15th century but for the prophets of the *Puits de Moïse*.

See Henri David, *Claus Sluter* (1951). (D. Ko.)

SMALL ARMS, MILITARY. In military language, the term small arms includes a great variety of weapons designed to be carried on the person and held in the hands when used, or fired from light supports. Small arms are light, portable weapons distinguished from heavy artillery-type weapons that must be fired from mobile carriages or fixed mounts. Not all of them are small. During the first half of the 20th century the U.S. army fixed the dividing line between small arms and artillery at calibre .60, but this line is no longer universally observed because of the development of portable rocket launchers and recoilless rifles. Small arms are often grouped in three broad categories: handguns (pistols and revolvers), shoulder weapons (muskets, rifles, carbines and others) and edged weapons (swords, daggers, pikes, lances bayonets, etc.). After the invention of machine guns late in the 19th century, these weapons were assigned to the small-arms category although they were far heavier than rifles and normally had to be fired from a bipod, tripod or other support. A narrow interpretation of the term has been adopted for this discussion. There is a separate article on MACHINE GUN, another on PISTOL AND REVOLVER and still others on edged weapons (*see* BAYONET; DAGGER; DIRK; LANCE; and SWORD). This article deals primarily with shoulder firearms, chiefly muskets and rifles. It treats the subject in broad historical terms to show the development of the basic principles of these weapons and their ammunition from their first appearance in the 14th century to the present day.

The following outline indicates the main topics covered in the article:

I. HISTORICAL DEVELOPMENT TO 1900

A. Early History

1. Hand Cannon.—The first portable military firearms probably developed in the second quarter of the 14th century. The earliest written records date from the 1360s, but it would seem that these refer to weapons already in use. Variously called hand bombards, hand culverins, *gonnes*, *Handbüchsen* (handguns) or, in modern parlance, hand cannon, these primitive small arms usually consisted of a tube 8–12 in. long, closed at the breech end, with a touchhole bored through the top about two inches from the breech. Usually they were made of brass or bronze, but there are a few references to iron barrels.

To protect the shooter's hand from the heat of the discharge, and also to provide a lever for controlling the recoil, these barrels were attached to a straight wooden haft from five to eight or more feet in length. There were several means of attachment. Sometimes the tube was simply lashed to the haft with iron bands; sometimes it was set into the haft as well as being lashed by the bands; sometimes a socket was fastened to the breech end into which the haft could be inserted; and sometimes the breech was extended in a spike or tang which could be driven into the haft. All these variations are found in specimens made before 1400.

A German manuscript of about 1390 survives to indicate some of the details of loading and firing. The barrel was filled three-fifths full of powder well rammed down. Then a wooden sabot or wad was added, and finally the ball. The charge was ignited by inserting a red-hot wire through the touchhole in the top of the barrel or by using a glowing coal held in tongs. An improvement that was probably in use by 1400 was the use of a "match," a length of loose hemp rope soaked in a solution of saltpetre or spirits of wine so that it would burn slowly and steadily, much in the manner of the modern punk used to light firecrackers.

There were several methods of handling these guns, depending somewhat on their size. Small ones could be managed by one man, who clamped the haft between his left arm and his body and supported the piece just behind the breech with his left hand while he applied the wire or match with his right hand. In other instances the butt was rested on the ground and the fore end supported by a forked rest; the shooter had only to steady the weapon while he applied the fire. Still other guns needed the services of two men to hold and shoot them.

As time passed, improvements came rapidly. The touchhole was moved from the top of the barrel to the side, where it was better protected from the weather. A pan to hold a small amount of powder was affixed outside the touchhole to provide for surer ignition; the pan was soon fitted with a movable cover. The barrel was lengthened. The haft was shortened and broadened so that it could be held against the shoulder, and gradually a curve was introduced so that the recoil was directed upward instead of directly back against the user. The curved stock is thought to have developed first in France just before 1500.

Some years earlier, certainly before 1425, a most significant advance occurred with the addition of a pivoted S-shaped bar of metal with a pair of jaws on the top end for holding the match. Now all that the soldier needed to do was to raise the lower end of the lever, or serpentine, and the lighted end of the match would be automatically depressed and brought into contact with the powder in the pan. Only the pressure of a finger was necessary. One hand could be used for supporting the gun while the other controlled the serpentine. The shooter could look where he was aiming rather than fix his attention on the pan to make sure he touched the coal to it.

2. Matchlock.—The final major advance in the development of small arms fired by a lighted match came about 1450 with the development of the matchlock. This improvement consisted of adding a trigger and connecting the serpentine to it by a simple link arrangement so that it acted against a spring. Pressure on the trigger depressed the serpentine and fired the gun. When the trigger was released the spring raised the serpentine and held it away from the pan. All working parts were now placed inside the lock plate and protected. It was at last a true lock. Further developments consisted only in lightening and improving the design of the weapon for easier handling and in replacing the early lever trigger with one that acted against a sear much in the manner of modern firearms. This last advance took place shortly before 1600.

Many names were applied to these early matchlocks, including arquebus (*q.v.*), *Hak-büchse*, hacquebut, hagbutt, hachbuss and other similar terms, as well as caliver and musket (*q.v.*). Because of the similarity of the terms and the indefinite and careless way in which they were used by contemporaries, much has been written in an attempt to obtain accurate definitions. Actually, they seem to have meant different things in different countries and in different periods. This is particularly true of the word arquebus and its cognates. Some authors applied it indiscriminately to any firearm. Other and more careful writers used it to designate a gun that was lighter than a musket and could be fired without a rest, thus making it for a short period synonymous with caliver. Still later, at the beginning of the 17th century, it was used to designate a wheel lock (*see* below) as opposed to a matchlock.

The term musket has always referred to a heavy military firearm. It is generally believed that the term was first used by the Spanish (*mosquete*) to denote a military firearm developed shortly before 1550 and introduced into the Spanish service by Fernando Álvarez de Toledo, duque de Alba. These first muskets weighed about 20 lb. and had a bore of 8 or 10 gauge. (In this sense, gauge indicated the number of spherical lead balls of the same diameter as the bore that were required to reach a weight of one pound.) As years passed, the size was reduced until by the middle of the 17th century the standard English musket weighed about 16 lb. and fired a 12-gauge ball from a 10-gauge bore.

Although the matchlock was a tremendous improvement over the primitive hand cannon, it still had many very serious drawbacks. It was slow and clumsy to use. The lighted match was a decided liability! It was a constant hazard in the presence of powder, and could not be used in the wind or rain; its glow and smell prevented its use in an ambush; it could not be lighted and used at a moment's notice but had to be kept burning whenever it seemed there was even a remote possibility of action.

Despite these many disadvantages, the matchlock remained the principal military firearm of Europe for many years after better and more efficient arms were developed. It was not completely supplanted in many armies on the continent until about 1700, although in America the change had taken place as much as 75 years earlier.

3. Wheel Lock.—Chronologically, the first of the improved ignition systems that eventually supplanted the matchlock was the wheel lock. Possibly invented by Johann Kiefuss of Nürnberg, Ger., about 1515, this lock worked on the same principle as the modern cigarette lighter: the spark was produced by holding a piece of iron pyrite against a revolving rough-edged wheel. The mechanism devised to produce this action was considerably

FIG. 1.—GERMAN WHEEL LOCK MECHANISM (C. 1565), PHANTOM VIEW: (A) RIGHT SIDE, (B) LEFT SIDE

more complex than the matchlock, yet it was sturdy and not likely to get out of order easily. The power for revolving the wheel was supplied by a heavy V-shaped mainspring. This spring was attached to the spindle of the wheel by a short chain of two or three links. When the wheel was wound by hooking a key or spanner over the outside shank of the wheel, this chain was wrapped around the spindle, and the mainspring was compressed and locked in position by a laterally acting sear that engaged a hole in the inner surface of the wheel.

The flashpan of a wheel lock was attached to the lock plate just as it was in the later matchlock. It differed from the pan of a matchlock in that it was pierced in the bottom to allow a portion of the wheel to intrude; and instead of a pivoted cover it possessed a sliding cover that was connected with the internal lock mechanism. The pyrite was held in the doghead, a miniature vise mounted on an arm that pivoted just in front of the pan. A spring fastened on the outside of the lock plate just below the arm of the doghead acted upon the arm in such a way that when the head was placed against the pan cover in firing position a constant downward pressure was maintained.

The loading and firing of a wheel lock was a comparatively simple and sure process. First, the wheel was wound. Then the charge was placed in the barrel in the normal manner. Next, the pan was filled with priming powder, the cover was slid shut and the doghead pushed down against it. The trigger was then pulled. The pressure on the trigger released the sear from its lodging in the hole in the wheel. The wheel thus freed began to turn, and as it did so a cam attached to it struck against a bar connected to the pan cover and automatically opened the pan. The doghead with its piece of pyrite, which had been held against the pan cover by its spring, was thus forced against the part of the revolving wheel that intruded through the slot in the pan. A strong series of sparks was produced, and the priming powder ignited.

The wheel lock was a tremendous improvement over the matchlock. The lighted match was no longer needed. The weapon could be carried ready to fire at a moment's notice. It could be fired with one hand, thus making the pistol practical; and it could be fired from horseback. As cavalry could now be armed with firearms, radical changes in tactics resulted, especially in Germany and northern Europe.

But the wheel lock was an expensive weapon; it never succeeded in supplanting the matchlock as the standard European military firearm. In America it was widely used because conditions there demanded a faster and more reliable gun than Europeans found necessary. In Europe generally it remained the weapon of horsemen and special troops.

4. Flint Arms.—The ignition system that finally supplanted the matchlock was a simple mechanism that produced its spark by striking flint against steel in a procedure similar to that for lighting household fires. In firearms the flint was held in a vise on one end of an arm, known as the cock. The other end of the arm was pivoted on the lock plate so that the flint-bearing end could be swung in an arc in the direction of the steel. The steel, which was also called the battery (now sometimes called the frizzen), was mounted on another pivoted arm and placed in a position opposing the cock. The flashpan was placed directly below the battery. When the trigger was pulled, the cock, impelled by a strong spring, moved forward in a short arc. The flint, held in the jaws of the cock, struck the steel a glancing blow producing a shower of sparks that dropped into the priming powder in the pan. If all went well, the flash of the priming powder penetrated to the powder in the bore and fired the weapon. But sometimes this failed to happen and there was only a "flash in the pan."

Modern students recognize at least six distinct types of flintlocks: the snaphance, English lock, dog lock, Scandinavian snap lock, miquelet lock and the "true" flintlock. These terms denote both different evolutionary stages in the development of the flintlock and regional variations. The first of these forms to appear was the snaphance, believed to have been developed in Scandinavia and the Low Countries about the middle of the 16th century. It was characterized by a separate battery and pan cover. Its name was derived from the Dutch words describing the action of the cock, *snaphaan*, or "snapping cock." This term was also adopted by English writers and used by them for over 150 years to indicate any form of firearm with a snapping cock, thus causing much confusion among arms historians in later years.

The miquelet lock developed almost as early as the snaphance, but it was confined to southern Europe, principally Spain and Italy. An exceptionally strong and simple lock, it remained virtually unchanged from the time of its invention until the opening years of the 19th century. Its main characteristics were an external mainspring and a battery and pan cover made in one piece.

The Scandinavian snap lock was also a product of the 16th century. It, too, had an external mainspring, and sometimes the battery and pan cover were combined as in the miquelet. There were, in fact, many points of similarity between the Scandinavian

and southern European types, unusual for such widely separated areas. The principal differences were in the shapes of the parts and in minor mechanical details.

The English lock and dog lock were variations of the Dutch snaphance in which the battery and pan cover were made in one piece. The internal mechanism was the same as that of the snaphance. There was no half-cock or safety position, and thus on the dog lock a dog catch was pivoted on the outside of the lock to engage the tail of the cock and provide such a safety position. Both these forms were in concurrent use in England from the first quarter of the 17th century until about 1650, when the French flintlock began to supersede them. The dog catch, however, persisted on many guns until after 1700, though it no longer served a necessary function.

The true flintlock was invented in France probably by Marin Le Bourgeoys about 1610–15. It combined features of both the snaphance and the miquelet and produced a simple, safe and reliable weapon. The battery and pan cover were combined in one piece so that the striking of the flint on the steel automatically opened the pan, and the internal mechanism was altered so that there was a half-cock or safety position. From France this new lock quickly spread throughout most of western Europe, although it never succeeded in displacing the miquelet or, to a lesser degree, the Scandinavian locks. It soon became the standard system for all the better guns and after 1700 for almost all guns.

The chief advantages of the flintlock over the wheel lock lay in its simplicity and cheapness of construction and in the fact that the user no longer had to carry a separate spanner or wrench to operate it. Special troops were armed with the flintlock in Europe by 1650, and after 1700 it had completely replaced the matchlock as a military weapon. In America the change was somewhat more rapid; every colony had banned the matchlock by 1677.

5. Standardization of Arms.—The beginning of the 18th century also brought the standardization of military small arms. Some attempts at standardization had been made earlier, it is true, but real success was not achieved until well into the first quarter of the century. By that time royal manufactories and systems of inspection had been set up in several countries and official models adopted. Muskets were the first arms to be standardized in most countries. Pistols and carbines or musketoons followed.

The average musket of the period was a flintlock smoothbore weighing about 12 lb. Calibres ranged from .69 in France and Spain to .75 in England and even slightly larger in some of the German states. With such a musket a well-trained recruit was expected to be able to load and fire in 15 seconds.

These muskets were not noted for accuracy. The best that could be expected was to hit the figure of a man at 80 to 100 yd. The military men of the period were more interested in rapidity of fire than in accuracy; they operated on the principle of laying down fields of fire much in the manner of modern machine gunners. Carbines and musketoons were shorter and lighter versions of the musket and were carried by cavalry, artillery and other special troops. Pistols were still shorter arms, also smoothbore, with calibres almost as large and even less accurate. Most cavalrymen scorned them and looked on the sword as their only true and effective weapon. (*See* also PISTOL AND REVOLVER.)

6. Percussion System.—A Scottish clergyman, Alexander John Forsyth, revolutionized all firearms theory with the invention of a percussion compound that would explode when struck a sharp blow. Working at his manse, Forsyth made his first percussion lock in 1805 and patented it in 1807 after some months of experimenting at the Tower of London. His compound was basically potassium chlorate. When placed in a tube communicating with the bore of a gun and struck by the hammer it produced a flash strong enough to ignite the charge. Separate priming powder and free sparks were no longer necessary. Forsyth thus laid the basis for later self-contained metallic cartridges and for contact fuses in shells and opened a whole new field of possibilities.

The next task was to perfect methods of utilizing this new material efficiently. Pellets and tubes filled with the compound were tried in the so-called pill and tube locks. Then came the percussion cap claimed by several as an invention. Joshua Shaw, an Anglo-American living in Philadelphia, developed the device in the United States but was refused a patent because he was not a U.S. citizen at the time. The first caps, shaped somewhat like the top hat of the period, were made first of iron (1814), then of pewter (1815) and finally (1816) of copper. The bottom of the cavity contained a minute amount of the percussion mixture covered by a disk of tin foil; the whole was sealed and made waterproof by a drop of shellac. In operation, this cap was placed over a tube, known variously as a cone or nipple, that projected from the barrel. The hammer, acting exactly in the manner of the cock on flint arms, struck the cap a sharp blow and produced a flash that was directed by the tube into the bore where it set off the propellent charge.

Despite the obvious advantages of the percussion system, a number of years passed before it was adopted as standard for military small arms. Military men could appreciate the fact that percussion guns were simpler to make, were surer to go off, and were not affected by wind or even light rain. They saw, too, that it was no longer necessary to carry extra flints and to chip and adjust them as they wore down. Nevertheless, they were concerned about the supply of percussion caps, the methods of carrying them and the delicate process of applying them to the gun. Thus it was not until 1842 that either the United States or Great Britain began the manufacture of standard military muskets of the percussion type, though the United States had adopted the system for special weapons as early as 1833 and Great Britain in 1836.

B. Development of Rifling

Rifling, or the cutting of spiral grooves in the barrel of a firearm to impart a spin to the projectile and thus improve its accuracy, was invented between 1450 and 1500. Some authorities claim the invention for Leipzig, Ger., in 1498, while others assert that the honour belongs to Vienna. Be that as it may, a specimen exists bearing the arms of the emperor Maximilian I which can be dated definitely between 1493 and 1508. The grooves in many of these very early rifles were straight instead of spiral, and some students maintain that the purpose of the grooves was to receive the fouling from the gunpowder and not to impart stability to the projectile. Powder fouling was a serious problem, especially with the earliest types of black powder, and such grooves would collect the powder somewhat so that more shots could be fired between cleanings. At the same time, however, it should be noted that the theory of stabilizing a projectile by causing it to revolve on its axis was well understood at that period and was utilized on crossbow bolts and some arrows. This, plus the fact that many of the early grooves are spiral, would seem to indicate that perhaps both purposes were intended.

If a ball were to take the spin imparted by the rifling, it had to fit the bore tightly. This meant that the ball had to be forced down the bore with repeated blows of the ramrod, or it had to be wrapped in a greased patch of cloth or leather that would ease its passage while still permitting a tight enough fit for it to take the rifling. Both methods were used from an early date, and descriptions of them can be found in manuals of the late 16th and early 17th centuries.

Rifling a gun barrel was a comparatively expensive process, and there were other drawbacks about these guns that prevented their rapid adoption as military weapons. The tight fit required of the ball made loading a slow process, even when the greased patch was used. This was a distinct handicap from the military standpoint. Ramrods were apt to break because of the need to exert considerable pressure on the ball, and a gun without its ramrod was worthless in battle. The thicker barrels of the rifles tended to make them muzzle-heavy; they were even harder to balance with a bayonet. Use of the early plug bayonet that fitted into the bore was, of course, out of the question with rifles. Finally, it took more skill to use a rifle to best advantage, a decided drawback in the eyes of the men who had to drill raw re-

cruits and levies.

Despite these handicaps, some rifles saw military service at an early date. Christian IV of Denmark is said to have been the first to arm troops with this weapon early in the 17th century; soon thereafter the French royal horse guard could boast that they were armed with eight rifled carbines per troop. By the middle of the 18th century the use of the rifle as a military arm had spread widely on the continent, and most Scandinavian and Germanic countries had organized special troops provided with rifles. The Swedish model of 1761 was even equipped with a bayonet.

Great Britain lagged far behind the other nations of Europe in the adoption of rifles for military service. Some of the continental troops employed by the British in the various European wars of the 18th century had had rifles, it is true, but it remained for the American rifle, encountered by British troops during the French and Indian War and the American Revolution, to wield the deciding influence in introducing the weapon to the regular British service. Copies of the American rifles were made in small quantities and issued to special troops; the Highlanders serving in America had them at least as early as 1760, and thereafter the practice spread. The breech-loading Ferguson rifle, described below, was tried briefly in 1776–77 and again late in the century, followed by the famous Baker rifles for the first official rifle brigade in 1800. Interestingly, these Baker rifles followed German patterns more closely than they did American and were equipped with bayonets.

1. American Rifle.—The American rifles that so influenced the British had been developed by German and Swiss immigrants on the eastern seaboard, especially in Pennsylvania. For this reason they are frequently called Pennsylvania rifles and sometimes Kentucky rifles because of their popularity with the settlers of the territory that later became the states of Kentucky and Tennessee. The earliest of the rifles made by these immigrants in the 18th century were indistinguishable from the short, large-calibre rifles of their homelands. As the years passed, however, the colonists lengthened the barrels, decreased the size of the bore and added a brass patch box to hold the greased pieces of cloth with which they wrapped their bullets. In so doing, they achieved a distinctly American gun. Stocked in handsomely grained curly maple, it reached its fullest development between 1770 and 1810.

The American rifle was a supremely accurate weapon. In the hands of practised marksmen it could find its mark at unheard-of distances, striking a target at 300 yd., almost three times the effective range of the musket. For this reason it was an exceptionally valuable weapon for special troops such as light infantry and snipers who were supported by regular infantry with muskets. But because the rifle took considerable time to load and had no bayonet it could not replace the musket as the regular infantry arm. The tactics of the day called for rapidity rather than accuracy in laying down a field of fire before the enemy closed in with the bayonet and decided the issue in hand-to-hand fighting. This point has been overlooked frequently in the past by popular writers who were not trained soldiers and did not understand the tactical situation. A whole body of literature has developed criticizing the military authorities for not recognizing the superiority of the rifle and adopting it immediately as the standard infantry arm. George Washington, Anthony Wayne, Peter Muhlenberg, Daniel Morgan and other American generals, some of them trained riflemen themselves, recognized fully the values of the rifle but realized also that it needed improvement before it could replace the musket.

2. Ammunition for Rifles.—Attempts to make improvements in rifles occupied the time of leading gun designers throughout the western world for half a century following the American Revolution. The principal problem was to increase the speed of loading. Two notable attempts were made with the round balls that had always been standard for rifles. In Great Britain, the Brunswick rifle was designed to fire a ball with a raised band around its equator to fit the gun's two-groove rifling. The British government adopted the Brunswick rifle in 1836, but it fouled badly and was often called by its contemporaries the worst military rifle in Europe. In France Henri Gustave Delvigne designed a rifle barrel with a narrow chamber at the breech just large enough to contain the powder charge. When the ball was dropped loosely down the barrel so that it rested against the opening of this chamber, several sharp blows with the iron ramrod would expand its diameter and make it fit the bore tightly. This distortion of the ball affected its accuracy, however, and the loading process, though more rapid than that with the patched ball, was still slower than the loading of a musket.

The answer lay not in the round ball but in the elongated projectile. As early as 1823 a Captain Norton of the British 34th regiment found the right approach in a bullet with a base hollowed in such a manner that the gases produced by the explosion of the charge would expand it and cause it to press tightly against the sides of the bore. In 1836 the British gun designer William Greener developed an elongated projectile with a conical plug fitted into the base cavity. On firing, the plug was driven far enough forward into this cavity to expand the walls of the missile into the rifle grooves. Both these bullets were tested by the British government and rejected.

In France, Delvigne, who had given up his experiments on round balls and switched to cylindroconoidal projectiles, teamed up with Colonel Thouvenin of the French artillery to produce a new system, usually known today as the Thouvenin system or the *carabine à tige*. In this rifle a stout pin or *tige* just long enough to pass through the powder charge was fixed to the centre of the breech plug. When the cylindroconoidal projectile was dropped down the barrel, its base struck against this pin, which acted as an anvil for flattening the bullet under blows from the ramrod. Since the ramrod had a shaped cavity in its tip, the bullet retained its form and its accuracy. The pin had a tendency to bend after repeated use, however, and fouling presented a particularly difficult problem. The hammered bullet did not provide the answer.

It was another Frenchman who finally produced the solution. In 1849 Capt. Claude Étienne Minié perfected the projectile that made his name a household word throughout the world. In developing his bullet, Minié followed the pattern set by Norton and Greener—a cylindroconoidal slug with a hollow cavity in the base. At first Minié inserted in this cavity an iron cup that was driven forward by the force of the explosion to expand the base of the bullet until it fitted the bore tightly. Later cups of other materials were tried, and finally it was discovered that if the cavity itself were properly designed, no cup of any kind was necessary.

Here at last was the device that made the rifle a practical military weapon for all branches of the service. The Minié ball, as it came to be called, could be dropped down the barrel and rammed home as easily as a musket ball. The rifle could thus be fired as rapidly as the musket. As the rifle had the advantage of greater accuracy, only a few years passed before the smoothbore disappeared from the military scene. Rifled arms of the Minié system were adopted as standard by Great Britain in 1851 and by the United States in 1855.

In addition to the main course of rifle projectile evolution, there were also one or two side developments using specially shaped projectiles and bores that achieved some success. These were the oval-bored and hexagonal-bored rifles. In these systems, instead of the usual grooves, the whole bore twisted to impart the proper spin to the bullet. Among these types, the oval bore has the longer history. Of the many guns that attempted to utilize it, one of the best known was the Greene bolt-action rifle used occasionally during the American Civil War. The hexagonal bore and projectile are associated primarily with the English gun designer Sir Joseph Whitworth, who produced both cannon and small arms utilizing this system. His guns were supremely accurate, and many saw service in the American Civil War in the hands of Confederate troops.

C. Breechloaders and Repeaters

Attempts to produce breech-loading and repeating firearms date back almost to the first appearance of small arms. Breech-

loading cannon, in fact, predate the first handguns. Multishot firearms were known at least as early as the first part of the 16th century. Most of the primitive breechloaders used separate chambers that were wedged or screwed into place. A few used metal tubes surprisingly similar to modern metallic cartridges. All suffered from an excessive leakage of gas and flame and from the fact that fouling soon made them difficult or impossible to use. Multishot arms most often employed multiple barrels and locks, revolving cylinders or a Roman candle effect in which the priming charge set off the foremost explosive charge in a series of charges loaded one on top of the other in the barrel and a powder train carried the flame onward, setting off one shot after another until the barrel was empty.

1. **Lorenzoni System.**—During the first half of the 17th century an especially good breech-loading and repeating flintlock firearm was developed, possibly by the Florentine gunmaker Michele Lorenzoni, and its use soon spread throughout Europe and, by the early 18th century, to America. In Europe the mechanism is known today as the *système Lorenzoni;* in the United States it is called the Cookson type, since the first such gun described in an American publication bore the name of the British gunsmith John Cookson. In this firearm, the balls and powder were placed in separate tubular magazines in the stock. A single backward-and-forward motion of a lever on the reverse side of the gun caused a special revolving breechblock to select a ball and a charge of powder from their respective magazines, place them in their proper position in the barrel, prime the flashpan and set the gun at half cock.

Some guns based on this system were designed to fire five, six or seven shots. It was an excellent and efficient system, but its construction required the skill of a master gunsmith. It also suffered from the hazard of the possible ignition of the whole powder magazine if the breech were not closed properly at the time of discharge. Despite these drawbacks, guns of this type were still being manufactured as late as 1800.

2. **Ferguson Rifle.**—Among the breechloaders, the 18th century witnessed the development of several systems which, as far as is known, were the first such arms used by soldiers. France tried one in 1723, and Austria armed its dragoons and light cavalry with them in 1770. Both experiments were of brief duration. In England an excellent breech-loading rifle was developed slowly during the first half of the century, reaching its peak in time for the American Revolution. The man who brought this rifle to its fullest development was Patrick Ferguson of the British army, and 100 or 200 men under his command were armed with this rifle for a short time during the American Revolution.

The Ferguson system was simple and efficient. A plug operating on a screw passed vertically through the breech of the barrel. The lower end of this plug was attached to the trigger guard, which acted as a handle. One revolution of the trigger guard in a clockwise direction lowered the plug until its top was flush with the bottom of the chamber in the breech. The plug being thus depressed left a hole in the top of the barrel which communicated directly with the bore. In order to load the gun the barrel was pointed slightly downward, the trigger guard revolved and the plug accordingly depressed. A ball was dropped into the hole in the top of the barrel whence it rolled forward until stopped by the lands of the rifling at the end of the chamber. The ball was followed by a charge of powder, measured simply by filling the cavity of the chamber behind the ball. The trigger guard was then revolved in a counterclockwise direction, closing the opening in the top of the barrel and forcing out any excess powder that might have been poured in. The pan was then primed separately, and the piece was ready for firing. The Ferguson rifle was probably the finest military firearm used during the American Revolution. It could be fired six times in a minute. It was accurate and was equipped with a bayonet. Nevertheless, it did not meet with official favour, and its active career was brief.

3. **Hall Rifle.**—It remained for the United States in 1817 to adopt the first breech-loading rifle as a standard military arm that saw long service. This was the Hall rifle, a flintlock weapon invented by John H. Hall of Yarmouth, Me., in 1811. In Hall's system a pivoted breechblock containing the lock mechanism and the chamber could be tipped up, loaded and then closed and locked in position by a spring catch. Since the junction of the chamber and the barrel was a simple butt joint, there was considerable gas leakage. Nevertheless, the Hall system, in both flint and percussion, was used for rifles and carbines for almost 25 years, the last-known carbine contract being awarded in 1850. The Hall rifle also enjoyed the distinction of being the first military firearm made in America with completely interchangeable parts.

4. **Dreyse Rifle.**—In Europe the breechloader was also making its appearance on the scene. Between 1827 and 1829 Johann Nikolaus von Dreyse invented his famous needle gun, which was adopted by the Prussian army in 1848. Dreyse's gun used a long, sharp firing pin to pierce the charge of propelling powder and strike the fulminate primer located in the base of the bullet. This needlelike firing pin gave the gun its name and also proved to be the arm's major weakness, for it tended to break or warp during heavy use. Dreyse's breech-closing mechanism included the bolt action; it was the first appearance of that very important device and was probably Dreyse's greatest contribution to firearms design. Despite the weakness of the firing pin, the needle gun remained standard in Prussia until it was replaced by the Mauser in 1871. In France, Antoine Alphonse Chassepot developed a rifle similar to Dreyse's but with a shorter pin and an improved cartridge. Elsewhere, Norway adopted a breechloader with a tip-up breech designed by F. W. Scheel in 1842, and in other countries experimentation continued.

5. **Sharps Rifle.**—In the United States, Christian Sharps of Philadelphia, who had worked under Hall making the latter's breech-loading flintlock rifles, invented the first really satisfactory breech-loading system in 1848. In Sharps's guns the breechblock was raised and lowered in a vertical mortise by the action of a lever that usually served also as a trigger guard. When the breechblock was lowered, the chamber was exposed and a paper or linen cartridge could be inserted. As the breechblock was raised, it sheared off the rear of the cartridge, exposing the powder to sparks from the priming pellet, which was not contained in the cartridge but was fed automatically over the nipple by the action of the hammer. The Sharps action was very strong and tight. It allowed no gas leakage, and it would not bend or crack, even with excessively large charges. The basic Sharps principle, in fact, is still in use today on some heavy arms and small cannon in which strength is needed.

6. **Other Types.**—During the 1850s and 1860s a large number of breech-loading arms were developed in the United States, and most of them saw service in the Civil War. It was only the war, in fact, that permitted most of them to get into production, since they were not good enough to have survived in a civilian market. In 1863 the United States government decided to look toward the adoption of a breechloader for its principal infantry and cavalry arms. In 1866 it began the conversion of muzzle-loaders then in use, and in 1873 the first new breechloaders firing .45–70 (calibre .45 with 70 gr. of powder) metallic cartridges were manufactured. On these rifles and carbines, the top of the breech tipped up in a trap-door action allowing the insertion of the cartridge. The new metallic cartridge eliminated all worries about gas leakage, and the action was strong. The .45–70 Springfield remained the principal U.S. military rifle until it was replaced by the Krag-Jörgensen in 1892.

Meanwhile experimentation with repeating weapons had not ceased with the *système Lorenzoni* discussed above. The United States tried the Roman-candle principle briefly during the Revolution and again during the War of 1812. Sliding locks that could fire superimposed loads one after another also were tried. The British experimented with multibarreled carbines, and there were other attempts to obtain greater firepower.

7. **Pistols and Revolvers.**—The pistol makers were the first to achieve real success, first with the revolving barrels of the pepperbox and then with the revolving cylinders of the Colt revolver. The pepperbox pistols consisted of a series of barrels grouped around a central axis; they could be fired one after another by a

single hammer. The system had developed slowly over a century and a half, reaching its height during the 1830s and 1840s. By this time, all were percussion arms and all were muzzle-loading. On some the barrels revolved automatically; on others it was necessary to turn them by hand. Normally these pistols had from 3 to 6 barrels, but occasionally there were more—8, 10, 12 or even 18. When first developed, they were the fastest-firing guns of their time.

Like the pepperbox, the revolver also developed slowly over a period of centuries. It was made a really practical arm by Samuel Colt in 1830 when as a boy of 16 he whittled out a model of a pistol in which the cocking of the hammer automatically revolved the cylinder. Colt's revolvers were all percussion until after the close of the American Civil War. Each chamber in the cylinder was loaded separately with a combustible cartridge, and the individual nipple for each chamber was capped by hand. The Colt revolver was an excellent weapon and one of America's greatest contributions to small-arms technology. As such it was soon copied by a host of other designers, in both the United States and Europe, who sought in various ways to avoid the patents that Colt held in the United States, Great Britain and France and that protected his system until they expired in 1856. By that time the revolver was firmly established. (*See* also PISTOL AND REVOLVER.)

8. Later Development of Repeaters.—Further advances in the field of repeating arms waited upon developments in ammunition. The evolution of the cartridge is discussed below, but its tie-in with the invention of practical repeating arms is particularly important here, through the work of two U.S. gunsmiths, Horace Smith and Daniel B. Wesson. These two young artisans became friends in 1852 and together developed a new repeating pistol and rifle using a new cartridge. The repeating mechanism was an improvement on one devised some time before by Walter Hunt and Lewis Jennings. As strengthened and simplified by Smith and Wesson, it formed the basis for the Volcanic pistols and rifles of 1855 and, later, with further improvements by B. Tyler Henry, for the famous Henry and Winchester rifles.

Before the Henry rifle reached its full development, it acquired a serious competitor in the form of the Spencer rifle and carbine. Christopher M. Spencer patented his gun March 6, 1860. It was an excellent firearm with a tubular magazine for seven metallic cartridges in the butt. It was sturdy, did not get out of order easily and was a great favourite with troops during the Civil War, when more than 100,000 Spencer arms saw active service. After the war the Spencer company was purchased by Winchester, and manufacture of Spencer arms was discontinued.

During the second half of the 19th century almost all nations experimented with various repeating rifles and carbines. By 1900 almost all had adopted one form or another as their principal small arm. The Norwegians and Danes adopted the Krag-Jörgensen, as did the United States, after much experimentation with other systems, in 1892. The British adopted first the Lee-Metford in 1888, followed by the Lee-Enfield in 1895. The Germans chose the Mauser, and so on throughout Europe. All were bolt-action rifles with magazines for five or six shots. A few nations preferred the Winchester system, however, either manufacturing their own variations or buying arms directly from Winchester. Only the most backward clung to the old single-shot guns.

D. Ammunition

Many of the steps in the evolution of firearms design have been directly related to corresponding improvements in the types of ammunition available. It is impossible to understand one without the other.

1. Gunpowder.—First, there were improvements in gunpowder (*q.v.*) itself. From the time of its discovery in Europe, sometime in the 13th century, until the appearance of smokeless powder late in the 19th century, all gunpowder was composed of three essential ingredients—saltpetre, charcoal and sulfur. The earliest method of making powder was to grind these three ingredients and mix them together. This resulted in a black substance of about the texture and consistency of fine coal dust. This form of powder was known as meal or serpentine powder. It was explosive, but it had many distinct disadvantages. It was first of all unstable. It was also hygroscopic, and when stored in a damp place it formed lumps that would burn slowly but would not explode. If the powder were rammed into the barrel with too great pressure it would form a lump and lose much, if not all, of its explosive force. Even when the complete charge remained in its mealy form, not all of it burned, and a gummy residue quickly fouled the gun barrel.

There were other disadvantages that related primarily to shipping and storing serpentine powder. Because of the dusty nature of its contents, a quantity of highly explosive dust was given off every time a container of the powder was shifted or jarred, which created a distinct safety hazard. Also, since the mixture of the three ingredients was purely a mechanical alignment, there was a tendency for these materials to settle out according to their specific densities if the powder were allowed to stand undisturbed for any period of time. Consequently, the periodic inverting of powder kegs was an important part of the routine of every well-run magazine.

Despite these obvious drawbacks, serpentine powder continued in use as the main propelling charge in firearms until about the middle of the 16th century, when "corned" powder began to supersede it. Corned or granulated powder was made by moistening the mixture and squeezing the resultant mass through sieves under considerable pressure. Corned powder overcame most of the disadvantages of the serpentine powder, and, in addition, it burned much more rapidly and thus added considerable force to the explosion. For these reasons, corned powder quickly supplanted the earlier variety as the main propellant for firearms. Serpentine powder, however, remained as the principal material for priming for at least another century.

At first, gunpowder was carried in flasks or horns. During the first half of the 16th century a device known as the bandolier appeared and became popular in many parts of Europe and in America. It consisted of a number of cylindrical containers, each holding enough powder for one charge, suspended from a belt that could be worn over the shoulder. Usually there was also a little flask for priming powder, and a bag for the bullets, which were carried separately.

FIG. 3.—EARLY TYPES OF POWDER AND BALL AMMUNITION: (A) LATE 16TH-CENTURY PAPER CARTRIDGE WITH BALL ATTACHED BY FLANGE; (B) 17TH-CENTURY PAPER CARTRIDGE WITH BALL ATTACHED BY SPRUE

2. Cartridges.—None of these methods was entirely satisfactory. There was still the need for greater speed and safety. The answer lay in the individual cartridge. The first cartridges appeared in the second half of the 16th century. At first they were simply charges of powder wrapped in paper. The ball was still loaded separately. Before 1600, however, several methods had been devised for attaching the ball, and during the next century these were refined until by 1700 the ball was wrapped inside the paper with the powder in one self-contained unit. These paper cartridges were in widespread use in America by 1650, and they were adopted as standard by most European armies during the opening years of the 18th century. They remained standard as long as muzzle-loading arms were used. To use one of these

cartridges, the soldier simply bit off the end of the paper tube, poured a little powder into the pan (if the gun was a flintlock), dumped the rest down the barrel and then rammed the ball and the paper down on top.

The early breech-loading and multishot weapons brought forth a great variety of cartridges. Some were wrapped or covered with paper, some with linen, animal tissue, collodion, metal, rubber and even other materials. All, however, lacked an internal primer that would supply the spark to ignite the charge.

In 1846 a Paris gunsmith named B. Houiller patented two cartridges that represented the first completely self-contained metallic-cased ammunition for small arms. One, known today as the pin-fire cartridge, held a small percussion cap mounted sideways in its base with a pin poised above it and protruding through the case itself. A blow from the hammer drove the pin into the cap, exploding it and setting off the charge. The other was the first of the rim-fire cartridges with a compound of fulminate of mercury in a cavity that encircled the rim of the cartridge base. A blow from a sharp-nosed hammer set this cartridge off in the same manner as the percussion cap that utilized the same explosive compound. In these first rim-fire cartridges the fulminate of mercury also supplied the propelling force, and, as a consequence, the charges were weak. In 1856 Smith and Wesson produced a rim-fire cartridge with a suitable charge of black powder as well as the detonating compound, and thus developed a truly useful cartridge.

The rim-fire cartridge gained widespread acceptance for every sort of firearm, but it had certain defects which still had to be overcome. It was difficult to spread the detonating compound evenly all around the rim cavity, and if the rim cavity was not filled all the way around there was a chance that the hammer would strike a blank space and produce a misfire. Also it was difficult to produce a brass case strong enough to withstand the pressures developed by the heavy charges in large-calibre guns and still weak enough in the rim to indent easily under the blow of the hammer.

The final answer to these problems was found in the centre-fire cartridge that was developed at about the same time as the rim-fire. Many men in England, France and the United States contributed to its evolution. In 1852 Charles Lancaster of Great Britain invented a cartridge with an internal perforated disk forming a small cavity at the base. This cavity was filled with fulminate and exploded when a blow from the hammer crushed the compound between the base of the case and the inner disk. This system was improved by A. M. Pottet of France in 1857 with a design that allowed a percussion cap to be inserted in a domed cavity in the base. Colonel Boxer of the British Royal laboratory improved Pottet's design in 1867 and produced the basic form of one of the two standard types of centre-fire cartridges that are the universal standard—the type in which the anvil or inner surface against which the priming compound is crushed is made separately from the cartridge case. The other standard type was developed by Col. (later Gen.) Hiram Berdan of the United States in 1866. In it the anvil was formed as an integral part of the case. After 1867 there were minor improvements in design and manufacturing techniques, and smokeless nitrocellulose powder replaced black powder as the propelling charge, but there were no basic changes in these two systems. (Hd. L. P.)

II. 20th-CENTURY SMALL ARMS

By the year 1900, foot soldiers in the armies of all leading military powers had at their disposal a wide variety of high-powered repeating rifles, lightweight carbines, semiautomatic pistols and revolvers and fully automatic machine guns. All these weapons fired ammunition that was far superior to that in use a generation earlier, much of it being filled with the propellant known as smokeless powder. Lead bullets covered with a thin jacket of cupronickel or other metal could be fired with great accuracy and lethal effect at man-size targets more than 500 yd. distant; extreme ranges ran up to 3,000 yd. and more. Military small arms had not only become lighter, more dependable, more accurate and longer ranging than those of earlier years, but they had become faster firing. Rates of small-arms fire rose tremendously in the period 1890–1910 as magazine-fed repeating rifles and automatic machine guns became standard military weapons.

These developments in small arms changed the whole face of war during the first two decades of the 20th century. They helped bring to an end the long reign of the cavalry arm. They turned frontal attacks by infantry on well-defended positions into mass slaughter. The new small arms, along with improved artillery, forced armies to build elaborate fortifications or seek safety in underground trenches. For a time they so strengthened the defense that no army could hope to take the offensive against a determined enemy and gain more than a few miles without suffering heavy casualties. The new weapons led to a long period of tactical stalemate on the western front during World War I, a condition that stimulated development of a new weapon, the armoured tank, that was destined to play a major role in World War II. (*See* Tank.)

During the period after 1880 ingenious inventors brought forth such a great variety of small arms that a mere listing of them all, with but brief description of each, would fill a large book. As machine guns, pistols and revolvers are treated in separate articles, they are mentioned here only incidentally; this article is focused mainly on rifles, carbines and submachine guns, but does not attempt to describe or name all the countless varieties that have seen military service. It is limited to a discussion of broad trends of development, with specific mention of some of the most notable types. As the development of ammunition for small arms has been so closely related to development of the weapons themselves, some discussion of small-arms ammunition has been included.

A. Repeating Rifles

Among the many different types and models of military rifles that appeared during the 1890s and early 1900s, certain common characteristics stand out. They all weighed between 8 and 10 lb., had barrels ranging from 24 to 30 in. in length, and were between 43 and 52 in. in over-all length. The new rifles were shorter and lighter than their predecessors of the mid-19th century, and they fired ammunition of about calibre .30 (7.62 mm.) rather than the heavier bullets of earlier years. They were magazine-fed and were usually loaded by five-round clips or chargers. They were designed to be rugged enough to withstand hard usage and to keep firing even under the worst weather conditions, though further improvements along these lines were constantly being sought.

The military rifle most widely used and copied during the first quarter of the 20th century was the German Mauser. It had first appeared in Germany in the 1880s and over the years had been adopted by a score of countries other than Germany. No other military rifle ever enjoyed such wide use. A bolt-action piece loaded with a five-shot charger, the Mauser was produced in many models, including both a standard rifle (*Gewehr*) and a shorter carbine (*Karabiner*). Improved models of 1898 served as the basic weapons of the German infantry through World War II.

1. Bolt Action.—The term bolt action calls for some explanation because it is fundamental to an understanding of all modern rifles. The bolt or breech mechanism of a rifle operates on the same principle as the sliding bolt used to lock a door, though it is far more complicated and its manufacture calls for much more precise workmanship. The typical rifle bolt is a steel cylinder containing a firing pin; it slides back and forth in the frame or receiver. The bolt has a solid head and, like the door lock, is fitted with a projecting handle with a round knob at the end. One or more lugs near the front or rear of the bolt fit into slots in the receiver and hold the bolt firmly in place against the base of the cartridge in the chamber when the weapon is to be fired. When the trigger is pressed, a long slender firing pin within the bolt is pushed forward by a spring to strike the primer cap in the base of the cartridge. After firing, the shooter grasps the round knob, raises it slightly to turn the bolt and disengage the lugs, and then slides the bolt back to extract the fired case. Forward movement of the bolt strips a fresh cartridge from the magazine and forces it into the chamber; a downward pull on the knob locks the bolt in place. Straight-pull rifles such as the Austrian Mannlicher and

Canadian Ross require no turning to permit the bolt to slide back.

2. U.S. and British Rifles.—In 1892 the U.S. army adopted the Norwegian Krag-Jörgensen rifle in preference to the Mauser and many other weapons tested. Produced as both a rifle and a carbine, it underwent several modifications during its short period of service. In 1903 it was replaced by the Springfield rifle, a modified copy of the Mauser manufactured at the U.S. army's Springfield (Mass.) armoury and at Rock Island (Ill.) arsenal. An excellent rifle, the Springfield served as the basic infantry weapon of the U.S. army for the next 35 years and helped win for the U.S. soldier a world-wide reputation for rifle marksmanship. As late as World War II, modified Springfields with telescopic sights continued to serve as sniper rifles. The 1903 Springfield was a calibre-.30 weapon with a 24-in. barrel, about 6 in. shorter than the Krag-Jörgensen. For this reason, no carbine type of Springfield was considered necessary for mounted troops.

In the British army, too, during the South African War, there was a demand for a shorter rifle with a magazine feed that could serve for both infantry and cavalry, thus eliminating the carbine. A committee was appointed in 1900 to study the matter, and in Dec. 1902 a new rifle described as the "short, magazine, Lee-Enfield, Mark I" (S.M.L.E.) was adopted. It replaced the Lee-Metford (1888) and the long Lee-Enfield (1895). Its over-all length of 44½ in. was approximately 5 in. shorter than the "long rifle." The S.M.L.E. combined the bolt action developed by an American, James P. Lee, with the Enfield type of rifling. It fired rimmed calibre-.303 ammunition, and its bolt locked on the rear as did that of the Krag-Jörgensen. An improved model known as Mark III was adopted in 1907, followed by Mark III* in 1918, a model with no cutoff (a device to permit reloading with single cartridges) and no long-range sights. The S.M.L.E. was fed from a ten-shot box magazine loaded by five-shot clips or single rounds. Though not quite so accurate as the Mauser or Springfield at long range, the S.M.L.E. held twice the number of cartridges and was faster firing.

At the outbreak of World War I in 1914 the British army was about to adopt a new Enfield rifle chambered for calibre-.276 rimless ammunition. But, in the face of war, the British government abandoned its plans for mass production of a new rifle and new type of ammunition. Instead, the .276 rifle was modified to fire the standard calibre-.303 rim-type cartridges, and orders for its production were placed with factories in the United States. Production was slow, and by 1917, when the United States entered the war, British need for these rifles had declined while the U.S. forces were desperately short of Springfields. To meet this emergency the British rifles in production were converted to fire U.S. calibre-.30 ammunition and were standardized as the M1917, or American Enfield. Over 2,000,000 of these rifles were produced during the war at three U.S. plants. The Enfield thus became, in terms of quantity production, the leading U.S. rifle of World War I. The rifling of the Enfield, unlike that of most rifles of its era, consisted of five grooves with a left-hand twist.

Other notable military rifle types of the early 20th century were the Austrian Mannlicher, Russian Mosin-Nagant, Japanese Arisaka, French Lebel and Canadian Ross. As noted above, the Ross and the Mannlicher were of the straight-pull type. They suffered from frequent jamming in mud or sand, and the Ross was dropped during World War I because of frequent malfunctioning.

B. Semiautomatic Rifles and Carbines

All the rifles described above were repeaters, not automatics or semiautomatics. They fired one shot each time the trigger was pulled (or squeezed, to use the preferred military term), but after each shot the user had to pull back the bolt by hand to eject the spent case and then slide it forward to bring another cartridge into the chamber. By 1900, and even much earlier, firearms designers had begun to think seriously of developing semiautomatic or self-loading rifles that would automatically bring a fresh cartridge into firing position after each shot, using the force of recoil or gas pressure for the purpose. France and Germany experimented with semiautomatics on a small scale during World War I, France issuing a few of the St. Étienne model and Germany some Mondragons designed by a Mexican officer of that name. But neither type functioned well in combat. The United States was the first nation to achieve real success in this field.

1. Garand Rifle.—After a generation of experiment and test (mostly with calibre-.276 rifles during the 1920s) the U.S. army in Jan. 1936 adopted a calibre-.30 semiautomatic rifle developed by John C. Garand, a civilian engineer at the Springfield armoury. Replacing the 1903 Springfield, the Garand rifle, or M1 as it was officially designated, became the basic weapon of the U.S. infantry in World War II and the Korean war. It was a calibre-.30 gas-operated weapon fed by an eight-round clip and weighing about 9½ lb. Its 24-in. barrel was rifled with four grooves.

As the gas-operating mechanism of the M1 differed from the manually operated bolt described above, it merits brief explanation at this point. A small hole or gas port on the underside of the barrel near the muzzle permitted part of the propellent gases to escape into a small cylinder holding a piston that was connected to the bolt. As the gas pressure forced back the piston and the bolt, the empty cartridge case was ejected and the hammer was cocked. A spring then forced the bolt forward. As it moved forward the bolt stripped the top cartridge from the magazine and seated it in the chamber ready to fire. Gas pressure thus performed automatically the reloading task formerly done by hand. For this reason, weapons of this type are often called self-loading or autoloading.

With the Garand rifle the U.S. army adopted a new cartridge of the same dimensions as its predecessor but with a lighter bullet —152 gr. as compared with 172 gr. Some critics considered this a backward step but military authorities defended it on two main counts: first, the lighter bullet caused less recoil and thus helped the training of recruits in marksmanship; second, the extreme range of the heavier bullet—over 3,000 yd.—was of little military value and proved dangerous in target practice on 1,000-yd. ranges. Rifles were seldom used in combat beyond about 600 yd.

2. Johnson Rifle.—Soon after the Garand rifle was adopted in 1936, and while Springfield armoury was tooling up for its manufacture, a serious competitor appeared on the scene and precipitated a major rifle controversy in the United States. This was the semiautomatic rifle designed as a private venture by Melvin M. Johnson. It had a 22-in. barrel, weighed about 9½ lb., operated on the short-recoil principle rather than the gas system of the Garand and was fed with a ten-shot rotary magazine. Largely because of defects that appeared in the first production models of the Garand, there arose a demand that the Johnson be adopted in its stead. But, after much public discussion and extensive tests in 1939–40, the U.S. army decided to retain the Garand after improving its gas take-off. The Johnson rifle meanwhile was adopted by the Netherlands Indies forces and saw some service with U.S. marine corps units in World War II.

3. German and Soviet Rifles.—The German and Soviet armies also employed semiautomatic rifles to some extent in World War II, but their performance fell short of expectations. The German semiautomatics that saw most service were the models *Gewehr* 41, 41-W and 41-M, *Gewehr* 43 and *Karabiner* 43. All were gas-operated and fired 7.92 mm. cartridges. The 41 and 41-W did not have a gas port in the barrel but employed a cone attached to the muzzle to trap some of the expanding gas. As early as 1936 the Soviet army adopted the 7.62-mm. Simonov gas-operated rifle, which was capable of both semiautomatic and fully automatic fire. Its gas port and piston were on top of the barrel, thus resembling the German *Gewehr* 43. Another Soviet gas-operated semiautomatic rifle, the 7.62-mm. Tokarev, appeared in 1938 and 1940 models. But throughout World War II most German and Soviet troops carried manually operated repeating rifles or carbines.

4. Carbines.—Early in World War II the U.S. army again adopted a carbine. This time the carbine did not serve as a cavalry weapon, as had carbines of the 19th century, but as a defensive weapon for service troops and operators of crew-served guns whose positions might be overrun in mobile warfare. For such troops the pistol had too short a range and too little accuracy, while the standard rifle was unnecessarily heavy and

powerful. A gas-operated weapon developed by the Winchester Repeating Arms company, the U.S. carbine M1, was similar in design to the Garand rifle but was 8 in. shorter. It weighed only about 5½ lb. and fired a different type of ammunition from a 15-round magazine. The M2 carbine that appeared late in the war had a selector switch that gave the user a choice of fully automatic or semiautomatic fire; it was fed from a 30-round magazine. Some airborne troops carried a carbine (M1A1) with a folding skeleton metal stock.

The British army also employed light rifles or carbines for certain types of troops in World War II. Rifle No. 4, Mark I* weighed only 6¾ lb. and was sometimes described as a carbine. Rifle No. 5, Mark I* was a British carbine especially designed for jungle fighting.

Most rifles and some carbines were equipped with detachable bayonets or bayonet knives for hand-to-hand combat, though bayonet fighting was not common in World War II or the Korean war and many observers considered the bayonet obsolete. Another attachment, the grenade launcher, enabled troops armed with rifles and carbines to hurl antitank and antipersonnel grenades for short distances. (*See* BAYONET; GRENADES.)

FIG. 4.—7.62-MM. NATO CARTRIDGE

C. Rifle Developments After World War II

At the end of World War II small arms were overshadowed by the atomic bomb and long-range guided missiles, but they were by no means forgotten. All leading military powers sought to improve their small arms in the light of World War II experience. The main objectives were to make rifles lighter and faster firing. The United States and Great Britain, joined in 1949 by other members of the North Atlantic Treaty organization (NATO), made determined efforts to improve their military rifles and also to standardize their equipment, particularly ammunition. Agreement in this field was not reached overnight. The Korean war (1950–53) was fought in the main with small arms and ammunition of the World War II type.

1. New Cartridges.—Acceptance of a common small-arms cartridge came first, though not without some difficulty. The British government proposed that a rifle cartridge of calibre .280 (7 mm.) with lead-core bullet be adopted. The U.S. government favoured a more powerful cartridge of calibre .30 with steel core. After extensive tests the U.S. cartridge, known as T65 during its development at Frankford arsenal, gained NATO acceptance in Dec. 1953. Formal action to standardize the new ammunition for all NATO countries came in 1954. In line with the policy of using the metric system, the new round was officially designated Cartridge, NATO, Calibre 7.62-mm. Its length, 2.84 in., was ½ in. shorter than the existing U.S. M2 cartridge, and its weight was about 10% less. The saving in length and weight resulted from the use of improved propellants, such as ball powder, that required less space. The 165-gr. bullet of the new cartridge was capable of inflicting a fatal wound on personnel protected by standard steel helmets and body armour at a distance of approximately 1,000 yd. It was standardized for both rifles and machine guns. Many older weapons were converted to take the new round.

After years of studying ways and means of increasing the infantryman's chances of hitting his target when firing a small arm, the U.S. army in 1964 adopted the 7.62-mm. duplex ball cartridge (M198) that carried two bullets instead of one. The two bullets (each weighing 83 gr.) were generally similar in size and shape except that the base of the first contained a cavity into which the point of the second fitted. When the cartridge was fired the first bullet followed a normal trajectory but the second, which had a slightly slanted base, followed a spiral course around the flight path of the first. At 100 yd. the second bullet would strike somewhere within 11 in. of the point of impact of the first; at 300 yd. it would hit within about 31 in. of the first. The duplex cartridge could be fired in any 7.62-mm. rifle or machine gun.

2. FN Rifle.—The British government meanwhile brought forth a rifle, designated EM2, of unusual design and appearance, with pistol grip placed ahead of the magazine. It had a straight stock, weighed about eight pounds and was chambered to fire the .280 cartridge. The Belgian firm Fabrique Nationale d'Armes de Guerre entered the competition with another rifle, popularly known as the FN and officially designated the T48 in U.S. tests. It also was designed to fire the .280 cartridge. The ordnance department of the U.S. army carried on extensive development and test work at Springfield armoury with designs based generally on modifications of the Garand rifle to provide both automatic and semiautomatic fire. After field tests and prolonged discussion, reaching up to the level of the British prime minister and U.S. president in 1952, the British government in 1954 adopted the FN rifle, which meanwhile had been altered to fire the 7.62-mm. cartridge and designed in light-barrel and heavy-barrel models. Belgium, Canada and Australia also adopted the FN rifle in 1954.

The FN was a gas-operated weapon with selector switch for either semiautomatic or fully automatic fire. It weighed about 8¾ lb., had a 20-round magazine and extended to 44.4 in. over-all length, including flash suppressor. In appearance the FN was markedly different from weapons of the Garand type, for it had a separate pistol grip behind the trigger guard and a carrying handle that could be swung up above the barrel. Because its butt could be swung downward on a hinge, thus permitting access to the receiver mechanism, the FN was easy to field-strip and clean.

3. M14 and M15 Rifles.—In 1957 the U.S. army announced

Principal Dimensions and Weights of Representative Military Rifles

Country	Rifle	Calibre	Approximate weight (pounds)	Length over-all (inches)	Type
Switzerland	Schmidt-Rubin (1889)	7 5 mm.	9.8	51 5	straight pull repeater
U.S.	Krag Jorgensen (1892)	.30 in.	9 2	49	turning-bolt repeater
Austria	Mannlicher (1895)	8 mm.	8.4	50	straight pull repeater
Germany	Mauser (1898)	7 92 mm	9	49 4	turning bolt repeater
Russia	Mosin Nagant (*c.* 1900)	7.62 mm.	9	51 8	turning bolt repeater
U.S.	Springfield (1903)	.30 in.	8.7	43.2	turning bolt repeater
Japan	Arisaka (1905)	6.5 mm.	9	51	turning-bolt repeater
Great Britain	S M L E Mark III (1907; originally adopted 1902)	.303 in.	8.7	44.5	turning-bolt repeater
France	Lebel (1907; originally adopted 1886)	8 mm.	9.2	51.5	turning-bolt repeater
U.S.	Enfield (1917)	.30 in.	9.2	46 3	turning-bolt repeater
U.S.	Garand M1 (1936)	.30 in.	9.6	43.6	gas operated semiautomatic
Japan	Model 99 (1939)	7.7 mm.	7.7	45	turning-bolt repeater
U.S.S.R.	Tokarev (1938–40)	7.62 mm.	8.8	47.8	gas-operated semiautomatic
Germany	*Gewehr* 41-W (1941)	7.92 mm.	10.8	45	gas operated semiautomatic
U.S.	Carbine M1 (1941)	.30 in.	5.5	35.6	gas operated semiautomatic
Germany	*Gewehr* 43 (1943)	7.92 mm.	9	43	gas-operated semiautomatic
Great Britain (also Canada, Australia and Belgium)	Fabrique Nationale (FN), light-barrel version (1954)	7.62 mm.	8.7	44.4	gas-operated semiautomatic and automatic
U.S.	M14, light barrel (1957)	7.62 mm.	8.7	44.1	gas-operated semiautomatic and automatic
U.S.	M15, heavy barrel (1957)	7.62 mm.	13.7	45.5	gas-operated semiautomatic and automatic
U.S.	M16 (1960)	5.56 mm.	6.4	39	gas-operated semiautomatic and automatic
U.S.S.R.	AK (Avtomat Kalashnikov)	7.62 mm.	10.5	34.2	gas-operated semiautomatic and automatic
U.S.S.R.	SKS (Simonov carbine)	7.62 mm.	8	40.1	gas-operated semiautomatic

that it had adopted a new semiautomatic rifle designated the M14, known during its test period as the T44. A gas-operated weapon, the M14 was similar in design to the Garand, or M1, which it was eventually to replace. Its weight was 8.7 lb., approximately 1 lb. less than the Garand. Like the Garand, it was developed at Springfield armoury. It fired the standard 7.62-mm. NATO cartridge, had a magazine capacity of 20 rounds and could be fitted with a selector switch to permit semiautomatic or fully automatic fire. A notable feature of both the U.S. rifle and the FN was a slotted flash suppressor at the muzzle. The new U.S. rifle, like the FN, was manufactured also in a heavy-barrel version (M15) that weighed approximately 13¾ lb. and was better adapted for fully automatic fire. This heavy-barrel version was equipped with a bipod support for the muzzle.

Combined with the M60 ground machine gun, the new rifle formed a complete family of small arms for the U.S. army, all firing the same ammunition. The M14 rifle was designed to replace the Garand rifle, the carbine and the M3 submachine gun, except as the latter was used on vehicles. The heavy-barrel M15 was to replace the Browning automatic rifle (BAR) as the automatic weapon of the infantry squad. The 23-lb. air-cooled light machine gun was to replace three existing models of calibre-.30 ground machine guns. The new rifle and machine gun would thus reduce the number of weapons in the U.S. army's small-arms system from seven to three, greatly simplifying logistical support and shortening the time needed for troop training.

4. M16 Rifle.—A calibre-.22 (5.56-mm.) rifle came into the U.S. military picture in 1960 when the air force adopted it as a replacement for the calibre-.30 carbine carried by guards at air bases. Designated the M16, it had been developed commercially in the late 1950s and had come to be known as the AR-15. It was a gas-operated, magazine-fed rifle capable of both semiautomatic and fully automatic fire, and weighed only 6.4 lb. The army procured comparatively small quantities of the M16 for use by airborne troops and special forces.

5. Soviet Rifles.—The Soviet Union also adopted a new family of infantry weapons during the 1950s, including a rifle, submachine gun (*see* below) and light machine gun. All fired a standard short 7.62-mm. cartridge. The Soviet rifle, described as a semiautomatic carbine, was a gas-operated weapon with ten-round magazine and an attached folding bayonet. It weighed about 8½ lb. and had a stock of laminated wood. The Soviet light machine gun was designed to provide fully automatic fire for the rifle squad. It weighed about 14½ lb. and was fed by a drum-type magazine.

D. Automatic Rifles

Automatic rifles, sometimes classed as light machine guns, represent attempts to combine the burst fire of the machine gun with the mobile flexibility of the rifle. Their combat employment reached its peak in World War II, though several models saw service in World War I. The typical automatic rifle was a shoulder-fired weapon weighing between 20 and 30 lb. and equipped with a bipod to support the muzzle when firing from a prone position. One of the earliest weapons of this type was the 28-lb. gun developed by the U.S. army officer Isaac N. Lewis. The British army adopted the Lewis gun as a platoon weapon just before the outbreak of World War I, and it proved to be a major factor in British infantry firepower during 1914–18. It was later adopted by the U.S. navy but not by the U.S. army.

The most famous U.S. army weapon of this type, the calibre-.30 Browning automatic rifle (BAR), appeared too late to see service in World War I, but it served well for the next 40 years as the basic automatic weapon of the rifle squad. It was a shoulder-fired, gas-operated rifle weighing about 20 lb. complete with bipod support. A comparable British weapon that saw extensive service in World War II was the 22–26-lb. Bren machine gun, a weapon that by U.S. standards would be classed as an automatic rifle. The Bren took its name from Brno, Czech., where it was originally manufactured, and Enfield, Eng., where it was further developed. It was basically a calibre-.303 weapon but was produced also in 7.92-mm. size. A selector switch permitted either semiautomatic or fully automatic fire.

The German army used the MG34, developed secretly in 1934 in violation of the Versailles treaty, and the MG42, which had the extremely high cyclic rate of 1,500 shots per minute. For paratroops the Germans in 1944 adopted a special gas-operated 7.92-mm. rifle named *Fallschirmjägergewehr* 42 (FG42). It had a selector switch that permitted either semiautomatic or fully automatic fire. With sling, bayonet and bipod it weighed about 10½ lb. A 13-lb. light machine gun developed in 1940–41 by Melvin M. Johnson saw some service with U.S. troops, the Dutch and other Allied nations in World War II.

E. Submachine Guns (Machine Carbines)

Since their introduction by the Germans and Italians in World War I, these weapons have been known variously as machine carbines in Britain, machine pistols in Germany and submachine guns in the United States. They are small, light weapons standing between the pistol and the rifle. They are far simpler in design than machine guns but they offer rapid-firing action, either semiautomatic or fully automatic. In spite of their limited range and poor accuracy they have proved to be useful for paratroops, commandos, tank crews and others who require a light gun able to deliver a high volume of fire at close quarters. Submachine guns normally fire pistol-type ammunition—calibre .45 in the United States and 9 mm. in western Europe—at rates ranging from 450 to 900 rounds per minute. Nearly all submachine guns have short barrels and heavy bolts and operate on the plain blowback principle. (*See* Machine Gun.)

Among the earliest weapons of this type to see military service were the Bergmann Muskete, the Villar-Perosa gun and the Beretta machine carbine. In the United States the most famous submachine gun was that patented in 1920 by a retired army officer, John T. Thompson. Popularly known as the Tommy gun, it gained notoriety as the weapon of U.S. gangsters during the prohibition era. The U.S. army adopted it in 1928, and the British army also used it. The Thompson submachine gun weighed about ten pounds and fired calibre-.45 ammunition from a circular drum holding 50 rounds or a box magazine holding 20 rounds.

During World War II and the Korean war, all major armies employed submachine guns in considerable numbers. They all developed weapons of simple design intended for cheap mass production and weighing between seven and ten pounds. Best known among them were the British Sten, Australian Austen and Owen, Finnish Suomi and German Schmeisser (MP38 and MP40). The latter with folding stock, weighed about nine pounds, fired 9-mm. ammunition and was carried by paratroops and motorcycle units of the German army in its 1940 blitzkrieg. Later types firing 7.92-mm. ammunition were known as MP43, MP44 and *Sturmgewehr* 44. Following the German example, the U.S. army first simplified the Thompson gun and then turned in 1942 to a new all-metal submachine gun weighing about nine pounds and firing calibre-.45 pistol ammunition from a vertical magazine under the bolt. Officially designated the M3, it soon took the nickname "grease gun" because of its resemblance to the tool used to grease automobiles. The Soviet army also replaced its 1940 model (calibre 7.62 mm early in the war to speed production. First came the M41 PPSh. fed by a 71-round drum, and then the PPS-43 with folding metal stock and curved 35-round box magazine. The M41 gun was extensively used by the North Koreans during the Korean war. A new calibre-7.62 mm. Soviet submachine gun appeared in the 1950s. It weighed about 9½ lb. and was fed by a 30-round curved magazine. It was produced in two models, one with a conventional wooden stock and the other with a folding metal stock.

F. Antitank Weapons

To meet the need for a powerful infantry weapon to attack armoured vehicles, the British army adopted the Boys antitank rifle. It was much like an ordinary bolt-action magazine rifle but fired a heavy, calibre-.55 armour-piercing bullet at high velocity. A little over five feet in length, the rifle weighed 36 lb. and could penetrate 24-mm. armour at 100 yd.

The most revolutionary light antitank weapon that appeared in World War II was the shoulder-fired U.S. rocket launcher famil-

iarly known as the bazooka. It was one of the simplest weapons employed during the war, and one of the most effective. The bazooka was an outgrowth of efforts to fire a powerful antitank grenade from a rifle and thus give the infantryman a means of defense against tanks. As the open-end rocket launcher had no recoil, it could fire a heavier round than could a conventional rifle. The bazooka gained its remarkable armour-piercing capability from the use of ammunition designed on the shaped-charge principle. Its chief limitations were its short range, lack of accuracy and backblast. Though its bore diameter of 2.36 in. far exceeded the normal upper limit of calibre .60, the bazooka was usually classed as a small arm, or, more properly, an infantry weapon. The same was true of the 3.5-in. bazooka that saw service in the Korean war (*see* BAZOOKA).

During the 1960s the U.S. Army adopted a 66-mm. high-explosive, antitank rocket that could be fired by one man from a bazookalike carrying case, which was then discarded. Known as a light antitank weapon (LAW), the rocket and case weighed only 4½ lb. but were capable of knocking out a heavy tank.

G. Recoilless Rifles

Another new type of infantry weapon, the recoilless rifle, made its appearance in combat toward the end of World War II and saw much service in the Korean war. It had some of the characteristics of an artillery piece but, because of its light weight, was often classed as a small arm. Ordnance designers had long dreamed of creating a powerful weapon that would have no recoil and would therefore need no heavy recoil-absorbing mechanism. The dream was realized by designing a gun that permitted some of the propellent gases to escape through exhaust ports in the breech, thus giving the weapon a forward thrust equal to the normal recoil. The 57-mm. recoilless rifle developed for the U.S. army weighed less than 50 lb. and could be fired by one man from the shoulder (though not in the usual rifle firing position) or from a bipod or tripod mount. A larger 75-mm. recoilless rifle also saw some service with the U.S. army in World War II; after the war, 105-mm. and 106-mm. models were developed to be mounted on a jeep or fired from a ground support. In 1959 the U.S. army announced a new 90-mm. recoilless rifle said to be capable of knocking out the heaviest tanks. It was a 35-lb., four-foot-long weapon that fired a shaped-charge projectile to an effective range of 500 yd.

Recoilless weapons are characterized by their simplicity, lightness and vented breechblocks. They fire high-explosive and antitank ammunition of unique design. Their cartridge cases are perforated to permit a portion of the propellent gases to escape to the rear; their shells are pre-engraved (*i.e.*, with rotating bands notched to fit the rifling). Recoilless rifles have lower muzzle velocity and much shorter range than do guns or howitzers of the same calibre. One of the greatest drawbacks to their tactical use is the rearward blast that betrays their location and makes them unsuitable for use in confined spaces.

H. Ammunition Developments

Remarkable progress was made in the improvement of small-arms ammunition during the period 1880–1910, with still further development during the next half century. Smokeless powder, improved brass cartridge cases, better bullet design, jacketed bullets, and clips and chargers for loading magazines—these were among the most noteworthy developments of the pre-World War I era. The earlier shift from bullets of spherical to cylindroconoidal shape had stimulated a trend toward smallbore rifles, since an elongated bullet had less diameter than did a spherical bullet of the same weight.

1. Bullets.—After P. M. E. Vieille's discovery of so-called smokeless powder in the 1880s, this propellant came into general use, ending the long reign of black powder. It gave off less smoke than black powder but was not completely smokeless. The high muzzle velocities (over 2,000 ft. per second) attained with smokeless powder were too much for conventional soft lead bullets to withstand. Bullets tore loose from the rifling, failed to spin properly and emerged from the muzzle unbalanced and hopelessly inaccurate. The answer to this problem lay in the jacketed or metal-patched bullet—a lead core covered with a thin shell of steel or cupronickel. Credit for making great improvements during the 1880s in the work of earlier pioneers in this field is usually given to Eduard Rubin, a Swiss army officer. For a time the French army adopted a different solution, using a solid bronze bullet in its 8-mm. round for the Lebel rifle, but virtually all other nations adopted jacketed bullets, or compound bullets, as they were sometimes called.

Soon after the turn of the century another change in bullet design occurred when the pointed bullet, known as the spitzer type, gradually supplanted the round-nosed bullet that had been standard in all armies for many years. Another apparently trivial but actually important development came in the early 1900s with the discovery that further streamlining of bullets, accomplished by giving them a slight taper or boat tail at the base, increased their range. An early example of this type appeared in World War I, the French 8-mm. boat-tailed round known as *Balle D.* Some nations followed the French example, but others kept flat-based bullets in service for many years. Meanwhile the substitution of gilding metal (copper and zinc) and allied compounds for steel and cupronickel in bullet jackets was found to lessen bore erosion and metal fouling. Later, during World War II, when copper was scarce, the United States turned to the use of steel jackets coated with a thin deposit of copper or gilding metal.

Most early-20th-century rifle cartridges produced chamber pressures between 35,000 and 50,000 lb. per square inch and muzzle velocities between 2,000 and 2,800 ft. per second. They fired bullets that were a little more than one inch long and weighed between 135 and 244 gr. Their powder charges normally ranged between 30 and 50 gr. Cartridges varied in calibre from 6 mm. (.236 in.) in the U.S. navy's Lee rifle to 8 mm. (.315 in.) in the French Lebel, and in over-all length from about 2.90 in. to 3.35 in. Fired from a firm support at a target 200 yd. distant, the best ammunition would group ten shots within a circle about five inches in diameter. Using U.S. Springfields, expert riflemen could consistently hit a 20-in. bull's-eye at 600 yd.

2. Chargers and Clips.—The introduction of magazine rifles in all armies put an end to the older method of feeding from a tube in the butt or under the barrel, and the use of chargers or clips for loading became standard practice. These terms are often used loosely and interchangeably, but, for the sake of historical accuracy, a distinction is best observed. A clip was originally a light metal openwork box in which a small number of cartridges, usually between five and ten, were placed, one on top of the other, against a spring at the bottom. They all faced the same way and their bullet ends were exposed. The entire clip filled with cartridges was slipped into the magazine, the so-called *en bloc* system of loading. It remained there until all its cartridges were fired, then dropped out at the bottom or, on some models, popped out at the top. In contrast, a charger was merely a flat strip of metal with its edges curled slightly to hook over the rims or extractor grooves of a row of cartridges, usually five. To load a rifle, the bolt was drawn back, the charger holding a row of cartridges was slipped into position above the receiver, and the cartridges were pushed down into the magazine against a spring-supported follower. The empty charger was then discarded. The Garand rifle was loaded with a double-row, eight-round clip; the Springfield and other Mauser-type rifles were loaded from five-round chargers.

3. Types of Cartridges.—Three types of central-fire cartridges —rimmed, semirimmed and rimless—deserve some explanation. The first was the type developed on the pattern of the earlier rimfire case but operated on a different principle. It was a central-fire case and its rim was a flange at the base that could be gripped by the extractor hook to remove the spent case from the chamber after firing. The rimless type had no protruding flange but had instead an annular groove just forward of the base into which the extractor could fit; the groove thus served the same purpose as the rim. The semirimmed case was essentially rimless, but its base section had a somewhat greater diameter than the main body of the case, thus giving it some of the characteristics of both the rimmed and rimless types. The widely used Mauser family of

rifles fired rimless cartridges, as did the U.S. Springfield. British, French and Russian rifles fired rimmed ammunition.

Another feature of most modern cartridge cases is their bottleneck shape. As bullets of smaller calibre came into use at the end of the 19th century, ordnance designers had to narrow the mouths of cartridge cases and fit the bullets into them like corks in bottles. Retaining the standard size for the main body of the cartridge case provided room for a large powder charge without resorting to use of a much longer and narrow case. Most 20th-century military rifle cases assumed the bottleneck shape, but that for the U.S. carbine did not, nor did ammunition for pistols and submachine guns.

Three years after adoption of the Springfield rifle the U.S. army standardized the calibre-.30 M1906 cartridge, familiarly known as the .30-'06. It had a rimless case and fired a 150-gr. flat-based bullet. After World War I this cartridge was replaced by a more powerful type, with a 172-gr. boat-tailed bullet, known as M1. It had an extreme range of 3,500 yd., or nearly two miles. Its lead core was hardened with antimony and its jacket was of gilding metal rather than cupronickel. As noted above, the M1 cartridge was supplanted by a lighter (152-gr.) flat-based round, known as M2, in the late 1930s when the Garand semiautomatic rifle came into use. It remained the basic rifle round of the U.S. army until the 1950s when its replacement by the 7.62-mm. NATO cartridge began (*see* above).

During the second quarter of the 20th century another major advance in small-arms ammunition came with the introduction of noncorrosive primers. In the early 1920s manufacturers of sporting ammunition had brought forth cartridges containing no potassium chlorate, a substance that left a moisture-attracting residue in the bore and caused rusting if the weapon were not cleaned promptly after firing. U.S. military authorities were reluctant to accept new primer compositions without exhaustive testing, particularly in view of their problems with defective primers during World War I. The first large-scale production of noncorrosive military primers in the United States came during World War II when commercial firms manufacturing carbine ammunition employed their own primers with good success. Germany made extensive use of noncorrosive primers during World War II for 9-mm. and 7.92-mm. ammunition. In 1949 the U.S. army standardized a noncorrosive styphnate mixture for small-arms primers.

4. Special Ammunition.—The most noteworthy trend in small-arms ammunition development in the 1910–60 period was the appearance of many different types of ammunition to serve special purposes. The impetus for this development came largely from the employment of machine guns for aircraft and antiaircraft fire. In addition to the familiar type known as ball ammunition there were added others known as armour-piercing, incendiary, tracer, armour-piercing-incendiary and special types for launching rifle grenades. Whatever the type, the term cartridge was used to designate the complete round, including cartridge case, propellant, primer and bullet.

Ball ammunition is most closely akin to the lead spheres of an earlier age and is chiefly an antipersonnel round. Its core is of lead alloy or common steel. Despite its name, the bullet fired by a round of ball rifle ammunition is not actually ball-shaped; it more nearly resembles a short cigar, with the front end pointed (but not sharply pointed) and the other end flat or slightly tapered. The bullet of the calibre-.45 ball cartridge for pistols, revolvers and submachine guns is more nearly ball-shaped, with rounded nose and flat base.

Armour-piercing (AP) cartridges assumed great importance during and after World War I as a means of attacking tanks, planes and other armoured vehicles. In the U.S. army there was a strong tendency during and after World War II to use AP ammunition for all purposes and do away with ball ammunition. The bullets of AP cartridges normally consist of a hardened steel core, gilding metal jacket and a small amount of lead to fill the space between the point of the core and the point of the jacket.

Tracer cartridges contain a chemical agent that emits light or smoke to enable the shooter to see where his shots are going. Such ammunition proved to be of special value in adjusting the aim of machine guns in aerial combat and, to a lesser extent, in setting fire to gasoline tanks of enemy planes.

Incendiary cartridges contain a chemical agent that ignites upon striking the target. They are highly effective against aircraft with light armour protection carrying heavy loads of fuel.

Grenade cartridges are designed to propel grenades (*q.v.*) from rifles and, in some cases, from carbines. They have no bullet but contain a powder charge that propels the grenade from a launcher fitted to the muzzle.

Efforts to improve rifle ammunition during the decades following World War I were directed toward reducing barrel erosion, eliminating muzzle flash and attaining improved ballistic performance. One of the most notable developments was a propellant known as ball powder that was widely used in British ammunition and in U.S. carbine ammunition during the 1940s and in many other types in later years. Brass remained the preferred metal for cartridge cases in spite of extensive experiments with steel, aluminum and plastics. Brass was strong, nonrusting and could easily be worked into the desired shape; it was also sufficiently elastic to expand slightly under the pressure of firing and then to contract for easy extraction.

Bibliography.—*Early Development:* As the literature dealing with firearms is huge, readers with special interests would do well to consult Ray Riling, *Guns and Shooting: a Selected Chronological Bibliography* (1951), which lists almost 3,000 titles. Some of the most generally useful books are the following: Josef Alm, *Eldhandvapen* (1933); Torsten Lenk, *Flintlåset* (1939); J. N. George, *English Pistols and Revolvers* (1938) and *English Guns and Rifles* (1947); James E. Hicks, *Notes on French Ordnance, 1717 to 1936* (1938); J. Margerand, *Armement et équipement de l'infanterie française* (1945); W. Keith Neal, *Spanish Guns and Pistols* (1955); Harold L. Peterson, *Arms and Armor in Colonial America, 1526–1783* (1956); John G. W. Dillin, *The Kentucky Rifle* (1924 and subsequent editions); Ned H. Roberts, *The Muzzle Loading Cap Lock Rifle*, 3rd ed. (1948); Arcadi Gluckman, *United States Martial Pistols and Revolvers* (1939) and *United States Muskets, Rifles and Carbines* (1948); Berkeley R. Lewis, *Small Arms and Ammunition in the United States Service* (1956); William A. Albaugh and E. N. Simmons, *Confederate Arms* (1957); James E. Serven, *Colt Firearms, 1836–1954* (1954); Alden Hatch, *Remington Arms in American History* (1956); Lewis Winant, *Pepperbox Firearms* (1952), *Firearms Curiosa* (1955), *Early Percussion Firearms* (1959); Charles E. Chapel, *The Gun Collector's Handbook of Values* (constantly being revised); and Herschel Logan, *Cartridges* (1948). (Hd. L. P.)

SMALL BUSINESS, a term used to denote units of nonagricultural business enterprise below an arbitrarily determined size limit. Since it is arbitrary, the size limit varies from country to country and from time to time. The designation is established to serve as a guideline in carrying out government policies that aid smaller business firms in one way or another, or that exempt such firms from certain regulations that apply to large firms. The basic concept underlying most efforts to aid small business is that the existence of such enterprises is desirable and that they need special assistance if they are to meet the competition of big business.

In the United States, during and after the war, firms with fewer than 500 employees were classified as small businesses. In Western Europe a much smaller figure was generally used. In France, for example, the General Confederation of Small and Medium Enterprises considered manufacturing firms as small if they had from 6 to 50 employees; those with fewer than 6 employees were legally classified as artisan enterprises. In Great Britain the Board of Trade classified as small those manufacturing enterprises with 10 or fewer employees and those retail firms with fewer than 5 branches and 25 employees.

Most students of the subject argue that quantitative criteria are unsatisfactory and that some qualitative characteristic such

as function or form of ownership, should be used in defining small business. Thus it has been held in the United States that all independently owned and operated enterprises that are not dominant in their field should be considered small businesses. In Europe some specialists have contended that all firms engaged in "particular" production as distinct from "mass" production should be included in the category of small business. Such qualitative criteria extend the coverage of the term to a larger segment of the business population than do most quantitative definitions.

In the United States, the antitrust legislation of the 1890s was advocated in part as a means of protecting small firms; other laws adopted in the early 1900s were intended to aid small businesses, but it was not until the depression of the 1930s that small business legislation gained much recognition. The economic difficulties experienced by the great majority of small firms during the depression led to demands for governmental action in their behalf. Many state governments adopted laws that discriminated against chain stores and outlawed so-called "unfair trade" practices of big firms. The federal government passed the Robinson-Patman Act that restricted the discounts that manufacturers and wholesalers could grant to large retailers for mass purchases. Various measures to make credit more readily available to small firms were provided. Special small business committees were established in both houses of Congress; these committees conducted extensive hearings on small business problems, sponsored numerous studies, and proposed a variety of legislative solutions. During World War II the Smaller War Plants Corporation was created to assist small firms to obtain war contracts or subcontracts. The Servicemen's Readjustment Act made small loans available to returning servicemen who wanted to establish their own businesses. This legislative interest in small business continued after World War II, culminating in the establishment of the Small Business Administration in 1953. This agency extended loans to small firms that were unable to obtain credit from commercial banks. It also assisted qualified small firms to obtain government contracts, promoted research on small business problems, and gave advice to small firms.

Governmental measures in behalf of small business were usually defended in terms of the need to preserve competition or to encourage new investment. Often the several million small businesses in the United States were cited as the bulwark of the middle class and their preservation was called for on that account. Most of the legislation adopted in the name of small business, however, affected only a small percentage of the firms classified as small businesses, principally the larger ones. In part this was a result of the tendency to expand the size limits within which firms qualify as small, and in part it was a result of the greater ability of firms with several hundred employees to present their cases and to utilize the services provided. A few authorities frankly said that only such firms were worth helping.

Nearly all the governments of the nonsocialist countries of Europe adopted policies to assist or protect small producers and tradesmen. In many of these countries there were governmental or private agencies whose function it was to study and promote the interests of artisans and other so-called independent elements in the society. The depression of the 1930s stimulated demand for measures of protection. An important element in the demagogic program of German National Socialism was directed to these groups, but their interests were soon sacrificed to the requirements of war. In the years following World War II, as before, much of the interest in the small operator in production, trade, and services was explicitly related in most European countries to his putative role in the middle classes. Thus Belgium had its Ministry of the Middle Classes and its Institute for the Economic and Social Study of the Middle Classes, the Federal Republic of Germany its Institute for Middle Class Research, and the Netherlands its Middle Class Bank. All of these organizations were primarily devoted to the interests of small businessmen. In Great Britain little government legislation to assist or protect small business was adopted. In 1921 the minister of agriculture created the Rural Industries' Bureau to help rural area firms that employed 20 or fewer skilled workers, but this step was taken not so much to help small enterprise as to promote the welfare of the rural population as a whole.

In Asia, Africa, and South America an ambivalent attitude toward small business is sometimes found. The fact that small-scale production requires more labour per unit of output than does large-scale manufacturing causes some policy makers to look with favour on the former as a means of providing employment. Small business is also viewed as a source of entrepreneurship and of middle-class stability. However, the desire to secure the cost advantages of modern productive techniques, often available only in large-scale units, leads in some cases to conflicting programs.

In socialist countries varying policies toward small business have been followed. In the Soviet Union and in Communist China, after an initial period of toleration or even encouragement of small businesses while large enterprises were being nationalized and a socialist economy was being organized, small firms generally were either nationalized or incorporated in cooperatives. On the other hand, in Yugoslavia artisan firms with less than five employees are permitted to function as private enterprises.

The number of small businesses in the nonsocialist countries tended to increase as population and income increased. In the United States the business population rose from about 3,000,000 firms in 1929 to 4,700,000 in 1960. Most of these firms were very small, about 75% of them consisting of the operator and, at most, three paid assistants. Nearly half the firms with no more than three employees were engaged in retail trade and one-fifth were in the service industries. In Europe the numerical persistence of small producers and tradesmen received much attention in the arguments over the revisionist thesis of Eduard Bernstein at the turn of the century. The Marxist theory that capitalist development tended to polarize society into the two classes of capitalists and workers was interpreted by Bernstein to imply a prophecy of rapid decline in the number of small producers and tradesmen, although Marx quite clearly anticipated the emergence of new groups of the petty bourgeoisie. In much of Europe large sectors of the economy, particularly retail trade and the service industries, long seemed immune to the process of concentration and centralization that development of large-scale organization in these industries brought about in the United States and Great Britain. However, the rapid economic expansion in western Europe during the 1950s was accompanied by the introduction of new forms of large-scale enterprise and the growth of older enterprises. At the same time full employment made available alternative sources of livelihood. As a consequence, many artisans and small shopkeepers took jobs as employees. Although the number of small enterprises did not decline, there was a decline in the percentage of nonagricultural self-employed persons in the labour force of most western European countries.

The long-run future for small business in the nonsocialist countries is governed primarily by two opposing forces: the growth of their economies tends to increase opportunities for both small and large firms; the process of concentration of economic activity in large units of business tends to eliminate small firms. These two forces are closely interrelated. Economic growth has been associated with the rise and consolidation of large-scale enterprise and has involved both growth of population and increasing per capita incomes. It has been accompanied by expanding commercialization of economic activity and increasing division of labour. These developments have contributed to the expansion of the market that makes feasible large-scale enterprise, while the economies made possible by large-scale organization of economic activity have been a decisive factor in economic growth. Historically, the interplay of these forces has been evident, on the one hand, in the "squeezing out" of small firms from certain industries as a result of the competition from large firms and, on the other hand, in the emergence of new opportunities for small firms as a result of the expansion of existing industries and the development of new ones whose markets are too limited to permit large-scale organizations to function effectively. Thus the increased volume of products turned out by large manufacturing enterprises greatly expanded the opportunities for small firms in

retailing. One line of retailing after another has been invaded by large units of business as markets have been extended by growth of population, incomes, and mobility, and as technical and organizational problems have been solved. In the United States the corner grocery store, that epitome of small business, has given way in striking fashion to the supermarket; the number of retail grocery outlets has been greatly reduced.

Whether the proliferation of small business industries as a result of the development of new products and services will continue to occur at a pace that offsets the process of concentration into larger units of business remains to be seen. The growing concentration of population in metropolitan areas provides a greater base for large-scale enterprise in lines that have long been strongholds of small business. Furthermore, the struggle for diversification on the part of large firms, which reflects both a desire to spread risks and the process of capital accumulation out of retained profits, has led more and more of them to explore opportunities in industries traditionally considered the preserve of small business. However, the increasing share of the service industries in consumer expenditures as per capita incomes rise expands economic activities that are often not suitable to large-scale organization. In any case, it is evident that small business will long continue to provide a livelihood for millions of owners and employees and to produce a significant fraction of the goods and services demanded by consumers.

SMALL HOLDINGS. The term small holdings covers several categories of relatively small farm tracts. Throughout the world, the essential characteristics of small holdings include recognized rights to operate the land, a high ratio of labour to land with the labour furnished mainly by the operator and his family, and relatively low levels of farm production and income. In most parts of the world, the labour is mainly by hand with the assistance of one or two horses, oxen or cows and simple tools.

This article outlines the characteristics and traces the history of small holdings after the breakdown of feudalism and indicates their prevalence in the second half of the 20th century. Separate sections deal with farm ownership in the United States and discuss some of the economic aspects of small holdings. *See* also AGRICULTURE; FARM MANAGEMENT; FARM TENANCY; LAND REFORM; LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS.

Included in the commonly accepted meaning are the subsistence tracts of the peasant farmer and garden tracts and part-time farms as well as small family farms. The mechanized family farm, of substantial size in commercial agricultural areas, usually is excluded. Certainly excluded are the plantation, the estate, the collective farm and the factory-in-the-field farm. Many ranches, even if family operated, would not commonly be thought of as small holdings, for the size is an important, though not by any means the only, determinant. The United Kingdom Small Holdings act of 1892 and the Small Holdings and Allotment act of 1926 provided examples of legal applications of the term. In other countries somewhat the same results were accomplished by legislation not so exactly named.

Very much of the world's population lives on farms and perhaps three-fourths of the world's farmers live on small holdings. The farm population constitutes about 1,500,000,000 people or about [illegible] of the estimated total world population. Small holdings are most prevalent in Asia and other underdeveloped parts of the world but are also numerous in other countries. Population pressure on the land is sufficient in much of the world to reduce the average size of farms well within the small-holding limits. In most countries small holdings also are used by labourers and other part-time farmers for housing, subsistence and incidental agricultural production.

History of the Small Holding.—In Denmark, England and other countries of western Europe, governmental interest in small holdings was aroused by the breakdown of feudalism. The object of governmental programs was to provide holdings for labourers and tenants who were being dispossessed. As early as 1682 20 years before serfdom was abolished, it was decreed in Denmark that no farms that were large enough to support a family should be combined with other farms. This was an anticonsolidation rule aimed at landlords who had discovered that the prevailing three-field system was not very efficient and might be profitably replaced by improved rotation methods, thereby consolidating some of the peasant-cultivated land. But that would have meant less taxes and fewer soldiers for the crown—hence the rule that meant in practice that no tenant could be dispossessed. In the same country, as early as 1781–82, many of the agricultural labourers were by law given ownership of four to six acres of land to keep the individual available to work the lord's land. Comprehensive legislation after 1899 furthered the establishment of small holdings averaging five to seven acres, the government lending the prospective holder nine-tenths of the purchase price of land and buildings.

Later emphasis was on having a farm large enough to keep the farmer fully employed and provide a living for the family; hence 12½ ac. of land were set as a minimum goal for all farms. Still later government measures were directed at obtaining land for small holdings or to add to small holdings, as equitably as possible, from entailed estates and from the higher valued, more extensive holdings.

In England small independent holdings existed under the feudal system, their numbers being greater in some manors than in others. For centuries, through the modification and disappearance of the feudal system, the number of small holdings or family farms increased until they became the predominant form of land occupancy. This trend continued up to the last great enclosure movement beginning in the latter part of the 18th century. (*See* ENCLOSURE.)

The enclosure movement contributed greatly to a reduction in the number of small holdings and to an increase in the number of farm labourers.

The success of large numbers of small holdings was dependent on the common for pasture. When the common was enclosed an allotment was made to the commoner in proportion to his interest. These allotments were of little value to many small holders, however, because they were often far from the allottee's cottage and because he was obliged to fence them. Consequently many small holders sold their land to larger landowners and became labourers.

With the reaction to the materialism of the Industrial Revolution, the social and economic consequences of the decline of small holdings aroused the attention of the English government. The weight of arguments for small holdings resulted in reform legislation beginning with the Allotments acts of 1887 and 1890. The Small Holdings act of 1892 authorized county councils to create small holdings on a self-supporting basis where a need was proved to exist. Small holdings were legally defined in the Small Holdings act of 1892 as holdings of less than 50 ac. in extent or under £50 in annual rental value. In 1926 the limit of annual rental value was raised to £100. If an applicant could not purchase land he could obtain a holding on lease. The results of the act of 1892 were negligible largely because it was only permissive, and it was amended by the Small Holdings act of 1908, a much more comprehensive enactment, particularly in introducing the principle of central initiative and authority. This act instructed county councils to provide small holdings in response to the demand. In case the council failed to carry out its obligations the ministry of agriculture was given power to develop a plan. If a loss was actually incurred the ministry was authorized to bear one-half the loss.

Operations under the act of 1908 were suspended during World War I. Legislation following World War I had the main objective

of providing small holdings under particularly favourable terms for ex-servicemen.

The Small Holdings and Allotments act, 1926, renewed the powers of county councils to provide small holdings. In the event that holdings could not be provided without loss, the ministry of agriculture would contribute 75% of the estimated annual loss. Under this series of enactments a total of 28,700 small holdings were established from 467,000 ac. of land. Only a small part of this land was held by councils on lease.

In 1947 small-holding policy was made the subject of part iv of the 1947 Agricultural act. The objective emphasized in this act was the use of small holdings as a step in the agricultural "ladder" for farm families with little capital. Permitted sizes of holdings were increased to 75 ac. or £150 rental value. In 1958 a Small Farmers scheme was introduced providing grants to eligible small farmers for the purpose of carrying out approved plans for improving the farm business.

During the early 1900s small-holdings programs were established in many other countries, including Germany, Rumania, Hungary and parts of Russia immediately following the Revolution. The collectivization of agriculture greatly reduced numbers of small holdings in many Communist countries. However, in 1953 Yugoslavia instituted a policy permitting decollectivization of agriculture. Beginning about 1930, attention in France, Switzerland, Germany and other countries was focused on the consolidation of fragmented holdings and enlargement of excessively small holdings. A major share of the Mexican land reform was undertaken during the 1930s. After World War II land reforms favourable to small holdings were undertaken in Japan, Italy, Egypt, Formosa (Taiwan), Bolivia and other countries. (*See* also LAND REFORM.)

Prevalence of Small Holdings.—In England and Wales in the second half of the 20th century, 22% of the holdings of over 1 ac. were from 1 to 5 ac., 24% were from 5 to 20 ac. and only 36% of the holdings were of 50 ac. or more. The number of units under 50 ac. provides a rough measure of the importance of small holdings in Great Britain. They vary considerably in size, in returns and in types of products grown. Many of the holdings under five acres are cottage gardens or allotments. Some occupy small acreages with specialization in intensive enterprises such as growing vegetables or producing eggs. Others are larger and more diversified. Probably most of the holdings from 20 to 50 ac. are commercial units producing mainly for sale. In Ireland, long after the period commonly considered as the reform period, very small holdings continued to increase both in number and in percent of total, though average size remained fairly constant. Three-fourths of the holdings in Ireland are under 50 ac. In Germany and other countries of western Europe considerable permanent hired labour is used on farms of 20 ha. (hectare = 2.47 ac.) and over.

Data from selected countries show that the size distribution of holdings is highly variable from country to country, but small holdings greatly predominate. Moreover, allotments made as a part of land reform, as in Italy, are small—only one to five hectares per holder. The numbers of holdings reporting less than one hectare vary widely, largely because of the varying farm definitions used in various countries.

In eastern Europe small units were prevalent prior to collectivization. In Bulgaria in 1934 only 1% of the holdings were larger than 49 ac. Less than 3% of those of Yugoslavia in 1931 were more than 49 ac. Even in Hungary, with its large pre-World War II estates, 70% of all holdings in 1935 were in tracts of 7 ac. or less. It may be significant that in some of these countries members of the new state cooperative farms were permitted to retain small plots—of 0.5 to 1.2 ac. in Bulgaria and Rumania, up to 2.5 ac. in Yugoslavia and about 2 ac. in Hungary.

In Egypt, where 95% of those who own land have 5 ac. or less, expropriated land was to be distributed in units varying in size, according to quality, from a minimum of 2 feddans to a maximum of 5 feddans (about 2 to 5 ac.). In Iran units of 14.5 to 21 ac. each were distributed. In Iraq settlement after 1946 appeared to recognize that tracts could be too small; the Dujail project involved allocation of 62½ ac. per family from a tract of 75,000 ac. of newly irrigated, formerly desert land.

In the orient, holdings are extremely small and tend toward further reduction under the pressure of population. More than 90% of Japanese farmers work less than 2.0 ha. After World War II Japan instituted a comprehensive system of land reform. Under these laws strict upper limits were set on farm size. Numbers of small farms increased substantially but net productivity of labour apparently rose with increased savings and capital formulation. Very small farms are also characteristic of India and China. More than half the farms in India are under 2.0 ha. In the late 1950s considerable emphasis was placed on the formation of cooperative and collective farms in China.

In Africa small native holdings greatly predominate even in areas such as Nigeria, producing export crops of cocoa and peanuts for the world market. Ninety per cent of the non-European farms in Rhodesia also are in holdings of under 14 ac. Cultivation in these countries is by plow or hand hoe.

There is appreciable variation in the size of holdings in Central and South America. Chile, with 2.5 ac. of cropland per capita, has about 20 cultivated acres per person engaged in agriculture. On the other hand, in Guatemala more than one-fifth of all agricultural holdings are less than 0.7 ha. and more than 75% are less than 3.5 ha. Over half of the holdings in Puerto Rico are under 3.5 ha. in size. Even in Uruguay, which is still accepting settlers, 42% of the holdings are less than 20 ha. in size.

United States.—In the United States, even during the period of abundant land, relatively small holdings were generally favoured. In 1820 the minimum unit of sale of government land was lowered to 80 ac. Limitation of acreage of public land that could be acquired by one individual was early recognized. The Pre-emption act of 1841, as amended, provided that a settler could legally enter upon public land and establish a claim for not more than 160 ac.; he could not make more than one such entry, and such a claim could not be made by anyone owning as much as 320 ac. The Homestead act of 1862, under which something like 285,000,000 ac. were patented, provided that a qualified individual might acquire title to land, not to exceed 160 ac., by five years of residence thereon with improvements, or by six months of residence plus payment of $1.25 per acre.

The 1954 United States census of agriculture classified 4,782,000 holdings as farms. A postenumerative survey indicated that about 419,000 additional places that would have qualified were missed by census enumerators; most of the latter were small holdings. About 35% of the 4,782,000 farms enumerated operated less than 50 ac., and more than 50% were under 100 ac. In 1959 the U.S. census definition of a farm was changed to exclude a considerable number of the small holdings enumerated in earlier years.

Because of the wide variation in productivity, acreage is not a very satisfactory measure of size of farms in the United States. In terms of value of products for sale, nearly one-third of the farms are part-time and residential units, most of them classed as small holdings, with farm production for sale of less than $2,500. About one-fifth of the farms in the United States can be classified as small-scale units primarily dependent on farming for a living. While the number of small-scale farms was decreasing, they remained a substantial segment of U.S. agriculture, characterized by low levels of mechanization, relatively small acreages and underemployment of operator and family labour. A substantial number of the operators were 55 years of age or over.

Beginning in the 1930s the problem of the small farmer was approached in a modest way by the Farmers Home administration of the U.S. department of agriculture with a program of supervised credit and individual guidance for the development and enlargement of land resources and working capital. In 1955 a rural development program was initiated by the U.S. department of agriculture in several counties in areas where farm incomes were low, emphasizing the development of both farm and nonfarm resources. In the 1960s this program was substantially expanded.

Some Economic Aspects of Small Holdings.—Developments in machinery, equipment and modern aids and techniques focused

attention on the fragmentation of holdings in some areas and on the uneconomic sizes of fields and lack of the opportunity to make efficient use of modern agricultural machinery.

This situation suggested consolidation of small and scattered holdings and the injection of capital to mechanize the consolidated units to give at least part of the reorganized population more income per hour worked and turn part of the population to other work. The difficulty of attaining efficient production with a small land unit (except for a few types of intensive specialization) led to attempts to overturn the small-holding pattern in some countries.

Another aspect of the problem is what is called the underemployment of farm labour. It has been argued that many small holders value leisure and the satisfactions of self-employment more highly than the advantages they might gain from fuller or more productive employment. Furthermore, a high percentage of families on small holdings have some off-the-farm employment. In these cases the small tract can serve to provide a form of security plus some food and space for family living. But for many families more productive use of labour involves farm enlargement, occupational adjustments and the development of nearby nonfarm industries. *See* also Agricultural Economics; Farm Management; Land Tenure: Economic and Agrarian Aspects.

SMALL ISLES, a parish of islands of the Inner Hebrides, Inverness County, Scot. (Pop. (1961) 170. It consists of the islands of Canna, Sanday, Rum, Eigg and Muck, lying in the order named, like a crescent with a trend from northwest to southeast, Canna being the most northerly and Muck the most southerly. They are separated from Skye by Cuillin Sound and from the mainland by the Sound of Ardnamurchan. The surface is moorland, pasture and mountain (exceeding 2,600 ft. on Rum). The islands are rich in seafowl and Rum contains red deer and wildcats. The fisheries include cod, ling and herring. Steamers call at Eigg, Rum and Canna.

Antiquarian remains at Canna include a weather-worn sculptured stone cross and the ruins of a chapel of St. Columba. On the northeast coast of Eigg is a cave with a narrow mouth, opening into a hollow 255 ft. (78 m.) long. In it Macleod of Skye, toward the end of the 16th century, ordered 200 Macdonalds to be suffocated; their bones were found long afterward.

SMALLPOX (Variola), one of the world's most dreaded plagues, is an acute infectious disease characterized by fever and, beginning about two days later, an eruption which, after passing through the stages of papule, vesicle, and pustule (*see* Skin, Diseases of: *Types of Skin Lesion*), dries up, leaving more or less distinct scars.

The characteristic eruption may be so profuse as to be confluent, especially on the face, or so scanty that the lesions are missed altogether. The lesions are commonly more deeply seated in the skin than are the lesions of chicken pox and the scars are therefore more permanent than those of chicken pox, but mild forms of smallpox may also have comparatively superficial pocks, with correspondingly less tendency toward pustulation and less scarring.

These modifications, both toward fewer lesions and toward their being more superficial, may occur either naturally or because of vaccination that was not recent enough to give complete protection against contracting the disease. With nearly complete vaccinal protection, few lesions will appear; but even if vaccination had been effected many years before, smaller and more superficial lesions are the rule where an unvaccinated person would have a severe attack. Such superficial lesions are also characteristic of the naturally occurring mild strains of the disease (variola minor). Even with strains of full severity (variola major) there may be much variation in severity among the unprotected.

Besides the characteristic focal eruptions (papule to vesicle to pustule to scab to scar) there is sometimes a toxic eruption during the initial fever. These toxic rashes may be diffuse blushes on trunk or limbs somewhat suggestive of scarlet fever or measles; they may on the other hand be deeper red, with small hemorrhages like fleabites or larger blotches in the skin. They are unusual enough to be of not much importance except for the fact that the deeper red eruptions have often disguised the diagnosis so that smallpox is not thought of until the contagion has spread over a hospital or farther. Cases with such a hemorrhagic eruption are likely to be the most severe, even fatal before the characteristic focal eruption appears, and can carry an intense contagion.

Diagnosis.—Prompt diagnosis is of the highest importance in combating smallpox. Though general vaccination helps, there is no community anywhere so efficiently vaccinated as to prevent smallpox from occurring occasionally. The mechanical refrigerator is largely responsible for the scarcity of the disease in the United States and Europe: if a supply of refrigerated vaccine is available constantly, a screen of recently and successfully vaccinated persons can be thrown promptly around any cases that may occur. Better refrigeration, quicker transportation, safer and more regularly potent vaccine, and more enlightened sanitary practices also have caused marked reductions elsewhere in the world. Vaccine dried while frozen has proved advantageous for vaccinating large numbers of persons in regions where ordinary liquid vaccine would lose its potency due to temperature and transportation difficulties. Smallpox rates and infant mortality rates are two of the best indexes of living standards.

The scarcity of the disease has brought about a considerable dulling of a former keenness in diagnosis. Except for laboratory confirmation of the virus (*see* below), which should be sought at once, the surest criterion for diagnosis is the course of a typical case. It begins with fever 7–21 days after effective exposure, followed by papules appearing after 1–5 days of fever and becoming vesicles in 1–4 days, pustules in another 1–4 days, and crusting over (scabbing) in 2–6 days. The scabs fall off in 10–40 days after the beginning of the eruption, leaving pink scars which become white after months or years. Unfortunately this long-term diagnosis is too slow for the preventive measures demanded by the disease. Complete isolation of the patient, search for persons who may have been in contact with him, and vaccination of those who might be exposed should be begun within hours, not days, after the first trace of a case. Therefore an early diagnosis based on the distribution of the eruption, which can be used at any stage after it appears, is imperative.

The eruption of smallpox, whether scanty or profuse, has more lesions on the parts of the body exposed to irritation than elsewhere, more on the face than on the abdomen and chest, more on back of the arms and hands than on the front, more on the limbs than on the trunk, and more on the back than on the abdomen. Protected places such as the armpits, the depression of the eyelid, and the back of the ear (unless irritated by wearing glasses) are relatively spared. However, unusual and extremely severe forms of smallpox may be evidenced only by prostration, deep redness of the skin with hemorrhages, and sometimes a fatal outcome occurring before the delayed eruption of pocks with its characteristic distribution becomes apparent. The presence of vaccination scars should not influence the diagnosis of smallpox; immunity diminishes in some persons more rapidly than in others.

Of laboratory methods of diagnosis, the most trustworthy is the identification of the lesions produced on the chorioallantoic membrane of the chick embryo. This requires a minimum of three days and a laboratory with 12-day incubated fertile eggs, a skilled inoculator, and a pathologist trained to recognize the lesions. Microscopic examination, agar-gel precipitation, hemagglutination inhibition, and complement-fixation tests are quicker and helpful, but less definite in interpretation.

Cause.—Smallpox is caused by a virus of the poxvirus group whose particles, ovoid or rounded-quadrangular in shape, are relatively large. The virus can be cultivated in a developing chick

embryo and on some other living animal tissue.

Some virologists tend to regard the viruses of variola major, variola minor, cowpox, and vaccinia as distinct, on account of differences which breed true in laboratory passage and, by common observation, in natural passage. On broader grounds, however, it seems reasonable to regard them all as derived from the original smallpox virus. Each immunizes against all the others. Charles Armstrong has shown that by selective transfer a strain of vaccinia can be made to become much more virulent.

Method of Spread.—Each case of smallpox arises from contact, direct or indirect, with another case of the disease. There are no natural animal carriers or natural propagation of the virus outside the human body, and the virus ordinarily does not live very long outside the body nor is it ordinarily carried more than a few feet through the air. Nevertheless all articles which may have been contaminated from a smallpox patient should be thoroughly disinfected by heat before they come in contact with unprotected persons. Smallpox is one of the few diseases in which public-health regulations specify terminal disinfection (as by formaldehyde) of living quarters after removal or death of the patient. The virus may be carried passively by a third person, himself immune, from a sick person or from a corpse. The disease is presumably contracted by inhalation of particles bearing the virus; therefore persons having necessary contact with the sick should be thoroughly masked as well as gowned. Isolation must be much more rigid than with the other contagious diseases.

Treatment.—No specific treatment is yet known for smallpox. Prevention is by means of isolation and vaccination (*q.v.*). Of all widely prevalent diseases, this is the most completely preventable by public health measures.

History and Prevalence.—The Persian physician Rhazes about A.D. 900 wrote the first known account separating smallpox from measles, although Eusebius mentioned a Syrian epidemic in A.D. 302 and the term variola ("pox") was used by Bishop Marius of the disease in France and Italy in 570. About 1200 Gilbert of England first referred to smallpox as a contagious disease, but even this was continually contradicted—even by Thomas Sydenham (1675), who described the disease better than anyone before him.

Smallpox was pandemic in Europe in 1614 and epidemic in England during 1666–75, and there were scattered outbreaks in New England all through the 17th century. On account of their habits during sickness, the American Indians were severely stricken, and students have assigned smallpox as one of the chief reasons for the conquest of the land by the white men. Of course there were many mistakes in diagnosis, and smallpox was confused with the great pox (syphilis). William Heberden in 1767 first clearly distinguished chicken pox from smallpox, but even in the 19th century the great skin physician Ferdinand von Hebra of Vienna denied the difference. After the turn of the 20th century the predominance in some localities of very mild types gave rise to the thought that the mild type was a disease different from smallpox, but tests for immunity indicated that these are merely different forms of the same disease, each form generally breeding true to its type.

Statistics as to prevalence of smallpox must be accepted with some caution. Reporting is likely to be imperfect in the very regions where vaccination is imperfect. Asia and to a less extent Africa have been breeding grounds for outbreaks of the severe form of the disease in Europe and the United States. Not infrequent outbreaks arose from travelers from Mexico before that country undertook a thorough campaign of eradication.

Mild smallpox was once well established in the central and western United States, but the reduction has been so phenomenal that the elimination of the disease in the U.S., as far as indigenous cases are concerned, may be considered accomplished. Rapid air travel, however, emphasized the need for fresh vaccination of all international travelers.

SMART, CHRISTOPHER (1722–1771), English poet whose reputation perhaps rests partly on his strange personality. Browning saw him as a mediocre poet to whom a single flash of sublime poetic inspiration was granted in the *Song to David;* and an eminent surgeon has diagnosed from his poetry a classic case of cyclothymia, with its characteristic alternation of elation and depression. Neither, however, had a complete knowledge of his writings. The most significant addition to them was *Rejoice in the Lamb* (composed *c.* 1763; published in 1939), an antiphonal poem full of cryptic autobiographical references. This points directly forward to Smart's later and best poetry: *A Song to David* (1763), the *Hymns . . . for the Fasts and Festivals . . .* (1765), and the *Hymns for the Amusement of Children* (1770).

Smart was born on April 11, 1722, at Shipbourne Fairlawn, Kent, where his father was steward to William, Viscount Vane. After her husband's death in 1733, his mother moved to Durham, where the Barnard branch of the Vane family lived. Christopher's holidays from Durham Grammar School were spent at Raby Castle with the Barnards, whose patronage he enjoyed for most of his life. He was intellectually precocious, and at 17 was sent to Pembroke Hall, Cambridge, where, during a brilliant but erratic career, he became a fellow (1745), and held academic office. At about 27 he plunged into the literary life of London, though he continued to compete successfully for the Seatonian Prize, a yearly university award for a poem on the attributes of the Supreme Being. His five Seatonian poems held promise of his later religious verse.

In London Smart was associated as a hackwriter with the bookseller John Newbery (whose stepdaughter he married). Chronic extravagance and inebriety made his life unhappy. At least three times he was confined for madness—a mild religious mania. But he must have had an engaging personality, for among friends who helped him were Johnson, Garrick, Goldsmith, and Dr. Burney; and Fanny Burney speaks of him in her diary with pity and admiration. He died in a London debtor's prison on May 21, 1771.

Most of Smart's early poetry shows talent but little depth. His later religious poems were treated with kindly indifference by his contemporaries, but a change in taste has led later readers to perceive in them unique flashes of child-like penetration and vivid visual imagination. In some ways they foreshadow the poetry of Blake and John Clare.

SMART, JOHN (*c.* 1742–1811), one of the foremost English miniature painters, the place and exact date of whose birth are not known. In his youth he won a series of prizes from the Society of Arts. He exhibited with the Society of Artists from 1762 and became president of that body in 1778. Smart spent ten successful years in India from 1785 till 1795, becoming miniature painter to the nawab of Arcot. After his return to England he exhibited fairly regularly with the Royal Academy. Smart's first wife left him for William Pars, the watercolour painter, and he married once, and possibly twice, again. He died in London on May 1, 1811.

In an age prolific in miniature painters of the front rank, Smart's achievement is regarded as highly as that of his rival and contemporary, Richard Cosway. He employed entirely different methods. His brushwork was meticulous and his finish highly wrought; he used body colour to render the rich costume of the late 18th century. Though not acute analyses of character, his miniatures have great finesse and charm. Throughout his life Smart made a practice of dating as well as signing his works; on those he painted in India he added the letter I to his signature J. S.

See B. S. Long, *British Miniaturists* (1929); A. Jaffé, *The Art Quarterly*, vol. xvii, pp. 242–254 (1954). (G. Rs.)

SMEATON, JOHN (1724–1792), English civil engineer, builder of Eddystone lighthouse and founder of the civil engineering profession in Britain, was born at Austhorpe, Yorkshire, on June 8, 1724. He learned mathematical instrument making in Lon-

don and, through contributing scientific papers to the Royal society, was elected a fellow in 1753. A tour of the Low Countries during 1755, studying canals, harbours and mills, was the turning point in his career. In 1756–59 he built the third lighthouse on Eddystone reef, opposite Plymouth, with dovetailed blocks of portland stone, and this established his reputation (*see* LIGHTHOUSES AND OTHER AIDS TO NAVIGATION). In 1882 the upper portion was re-erected on Plymouth Hoe as a memorial. He also constructed the Forth and Clyde canal, built arched bridges at Perth, Banff and Coldstream, and completed the harbour at Ramsgate.

In 1754 Smeaton introduced cast-iron shafts and gearing into wind- and water mills, and received the Royal society's Copley medal for *An Experimental Enquiry Concerning the Natural Powers of Water and Wind to Turn Mills* (1759). He constructed a boring mill at Carron ironworks and, due to his improved designs, the Newcomen engine achieved its maximum performance. He designed large atmospheric pumping engines for Long Benton colliery in Northumberland, Chacewater mine in Cornwall, and the docks of Kronstadt in Russia. Smeaton was an original member of the Society of Engineers, founded in 1771, and in 1791 wrote his *Narrative of the Building . . . of the Eddystone Lighthouse*. He died at Austhorpe on Oct. 28, 1792, and was buried in Whitkirk parish church.

BIBLIOGRAPHY.—S. Smiles, *Lives of the Engineers*, vol. ii, rev. ed. (1874); Smeaton's *Reports*, 3 vol. (1812), *Papers* (1814); *John Smeaton's Diary of His Journey to the Low Countries, 1755*, with introduction by Arthur Titley (1938). (AR. S.)

SMEDEREVO, a town in the Socialist Republic of Serbia, Yugos., and a Danube port, lies 24 mi. (39 km.) ESE of Belgrade. Pop. (1961) 27,182. It is a walled town with 20 towers. It manufactures railway trucks and there is a steel mill. In the neighbourhood of Smederevo is believed to be the site of the Roman settlement Mons Aureus. In the 15th century when the Serbian despot George Brankovich became lord of Tokay (Tokaj) in Hungary, he planted vines from Smederevo on his estates there, and from these came the famous white wine of Tokay. Smederevo became the capital of Serbia about 1430 and was taken by the Turks in 1459. *See* also SERBIA. (V. DE.)

SMELL AND TASTE. Food flavour is man's commonest and most familiar smell (olfactory) and taste (gustatory) experience. Commonly misnamed taste, flavour is a composite of pressure, temperature, pain, and odour, as well as taste. Seeing and hearing also contribute to delight the gourmet. The olfactory component in flavour can be demonstrated by pinching shut the nostrils: a slice of raw potato then tastes the same as an apple; cinnamon yields only mild sweetness (a true taste) in addition to texture. Perfumes, on the other hand, primarily excite the sense of smell, although some may induce slight gustatory or tactual experiences.

The sensation (*q.v.*) that an entirely new synthetic chemical will arouse is not yet fully predictable before it has been tasted or smelled. The chemistry of odour and taste remains incompletely known. Many known relations concern the presence of specific atom types in chemical compounds. For example, mercaptans (*q.v.*) structurally resemble alcohols, but have sulfur atoms in place of the oxygen in alcohol molecules. Such sulfur substitution often leads to a markedly disagreeable change in odour; *e.g.*, the scent of a skunk is traced to *n*-butyl mercaptan; in water H_2O, sulfur substitution gives the odour of rotten eggs in hydrogen sulfide H_2S (called stinkdamp by miners); the analogue of odourless carbon dioxide CO_2 is carbon disulfide CS_2, with a distinctive smell that becomes especially nauseating in the presence of organic sulfide impurities.

Another approach explains odour in terms of molecular shape regardless of atomic constituents (J. E. Amoore, J. W. Johnston, Jr., M. Rubin). Thus camphor, cyclooctane, thiophosphoric acid dichloride ethylamide, and hexachlorethane (all with similar odours) have widely different chemical formulas, but their molecules are of similar shape and size. This interesting stereochemical theory awaited fuller empirical verification in the 1960s.

The common chemical sense, often classed with taste and smell (also chemical senses), depends on undifferentiated free nerve endings in the moist mucous membranes of the mouth, upper respiratory passages, and other body orifices. The common chemical sense mediates the mild pain of pepper or other irritant spices, whereas gustatory sensory qualities are characterized as salty, sour, bitter, and sweet; and odour as foul, fruity, burnt, fragrant, and so on. The common chemical sense, taste, and smell form a hierarchy in terms of increasing complexity of anatomical structure, sensitivity, and differentiation in sensory quality. In lower forms, especially aquatic organisms, these distinctions may not always be obvious because irritant, olfactory, and gustatory stimuli are all transported in the fluid medium; on land, odorous or irritating vapours are largely air-borne, whereas taste stimuli are in solution and stimulate by direct contact between solution and taste bud. In fishes olfactory pits or taste buds on whiskerlike feelers (barbels) and on other parts of the body surface indicate specific sensory functions. Taste and smell, being less informative and involving relatively simpler physical structures than those that mediate seeing or hearing, are often classified as lower senses. Among lower animals the chemical senses have particular significance in the selection and acceptance of foods, the avoidance of noxious agents, and the detection and attraction of sexual mates. Civilized man, more dependent on his higher senses, finds in his lower senses the flavour and spice of life.

SENSE OF TASTE

The sense organs for taste are goblet-shaped clusters of cells (taste buds) that open by a small pore. The buds contain slender gustatory cells with hairlike terminal microvilli projecting into the taste pore (fig. 1). In man and other mammals, taste buds are primarily found in the fungiform, foliate, and circumvallate papillae of the tongue (*q.v.*), and in adjacent structures of the throat. Sensory nerve fibres enter the taste buds, entwine, and contact one or more taste cells. When nerves to the tongue are cut, these fibres and the whole taste bud degenerate. If the nerve fibres regenerate, the taste buds are reconstituted from surrounding cells of the epithelium.

ADAPTED FROM A. J. D. DE LORENZO, "ULTRASTRUCTURE AND HISTOPHYSIOLOGY OF MEMBRANES" IN "OLFACTION AND TASTE," ED. Y. ZOTTERMAN; PERGAMON PRESS, 1963

FIG. 1.—MICROSCOPIC SECTION OF TASTE BUDS OF CIRCUMVALLATE PAPILLA

In invertebrates, the clearest distinction between taste and smell can be made in insects; there is also ample evidence that worms, gastropods, and other forms reject bitter substances but accept sugars added to their food. In insects, contact chemoreceptors are located on hairs of the legs and mouth parts. Localized stimulation of these hairs with sugar solution induces extension of the proboscis. This response may be inhibited by adding salt to the sugar solution. In flies, the labellar hairs contain four nerve fibres, only three of which appear to extend to the chemoreceptive tip (*see* FLY); electrical discharges in these fibres are found to follow chemical stimulation. Similar receptors occasionally are seen on the proboscis or antennae, but the latter more commonly function as olfactory organs.

Innervation.—There is no single sensory nerve for taste in vertebrates. In man, the anterior two-thirds of the tongue is supplied by the lingual nerve, the back of the tongue by the glossopharyngeal nerve, and the throat and larynx by branches of the vagus nerve, all of which mediate touch, temperature, and pain sensitivity as well as taste. The taste fibres of the anterior tongue leave the lingual nerve to form a slender branch (the chorda tympani) that traverses the eardrum en route to the brain stem. When the chorda tympani is damaged, as in removal of the eardrum, taste buds disappear and taste sensitivity is lost on the anterior two-thirds of the tongue on the same side. The taste fibres ascend to the medulla oblongata; at this and all levels of

the brain, taste fibres seem closely associated with touch and temperature neurons for the tongue. From the medulla the fibres ascend to a small cluster of cells in the medial part of the sensory nucleus of the thalamus. From here fibres proceed to the anterior cerebral cortex close to the sensory-receiving area for the mouth (*see* BRAIN).

The tongue surface is not uniformly sensitive. The middle surface is insensitive to taste, but there is sensitivity to salt around all edges, sensitivity to sweet primarily at the tip, sour at the sides, and bitter at the back. For many years it was believed that there were only four basic types of taste receptor, one each for salt, sour, bitter, and sweet. However, electrical impulses in the gustatory nerves of animals contradict this simple schema. Individual nerve fibres from the tongue show mixed sensitivity, in many cases responding to more than one taste stimulus; *e.g.*, acid plus salt, acid plus salt plus sugar. Records from individual taste cells show the same multiple sensitivity. The taste buds, therefore, seem to have different clusters or patterns of sensitivity. In some organisms certain taste receptors may be activated by water but inhibited by sodium chloride. Thus nerve impulses to the brain may be increased or decreased by taste stimulation. Gustatory perception depends on the processing of such impulses by the brain.

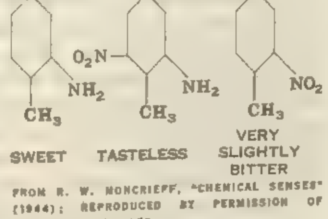
Chemical Factors.—There is no simple relation between chemical composition and taste quality except in the case of acids. The qualities of inorganic salts are complex, only sodium chloride yielding a purely saline taste. Sweet and bitter tastes occur in many different chemical classes.

Sour.—The hydrogen ions of acids are largely responsible for a sour taste, and sourness increases with hydrogen ion concentration; but this factor alone does not determine sourness. Weak organic acids such as the acetic acid of vinegar are more sour than would be predicted from hydrogen ion concentration alone (*see* ACIDS AND BASES; HYDROGEN IONS).

Salt.—Although a salty taste is often associated with soluble salts, most chemical salts, except sodium chloride, have such complex tastes as bitter-salt or sour-salt. Salts of low molecular weight are predominantly salty while those of higher molecular weight are bitter. The salts of heavy metals such as mercury have a metallic taste, although some salts of lead and beryllium are sweet. Both anion and cation (*qq.v.*) seem to influence taste quality and stimulating efficiency. In man the degree of saltiness decreases in this order: salts of ammonium, potassium, calcium, sodium, lithium, magnesium. The order appears different for other animals. (*See* also SALT.)

Sweet.—Except in the case of some inorganic salts of lead or beryllium, a sweet taste is associated largely with such organic compounds as alcohols, glycols, sugars, and sugar derivatives. The complex relation between chemical structure and sweet taste was not readily explained in the 1960s. This is particularly apparent for such synthetic sweeteners as saccharin and Dulcin. Sensitivity for these substances is especially remarkable; for sweetness to be just perceptible, saccharin need have only $\frac{1}{700}$ the concentration required for cane sugar. Spatial arrangement of atoms in the molecule is strikingly important; slight changes in arrangement within a sweet molecule (fig. 2) will make it bitter or tasteless. (*See* also CARBOHYDRATES.)

Bitter.—Bitter also is elicited by many chemical classes and is often found in association with sweet and other taste qualities. An increase in molecular weight of inorganic salts or an increase in length of the carbon chain in organic molecules may be associated with increased bitterness. The best-known bitter substances are the alkaloids (*q.v.*), which are often toxic, including quinine, caffeine, and strychnine (*see* POISONOUS PLANTS). Some of the lowest taste thresholds on



FROM R. W. MONCRIEFF, "CHEMICAL SENSES" (1944); REPRODUCED BY PERMISSION OF LEONARD HILL, LTD

FIG. 2.—EFFECT ON TASTE OF SLIGHT CHANGES IN MOLECULAR ARRANGEMENT

record are found in this class of agents (*see* PSYCHOPHYSICAL METHODS).

Some people cannot detect the normally bitter taste of such chemicals as PTC (phenylthiocarbamide) that have the thiocarbamide group

$$-\mathrm{N}-\overset{|}{\underset{\underset{\mathrm{S}}{\|}}{\mathrm{C}}}-$$

in the molecule. This form of taste blindness appears to be inherited as a Mendelian recessive (*see* GENETICS). About one-third of Caucasians cannot taste PTC; among Negro groups this proportion is about one-fifth. Evidence for such taste blindness has been observed only in primates, the gene responsible for the defect apparently having appeared at a relatively late stage of evolution. Taste blindness for thiocarbamides is not correlated with insensitivity to other bitter stimuli.

Factors Affecting Taste Sensitivity.—It has long been known that temporary taste insensitivity may arise at extreme temperatures, especially when a fluid is very cold. The optimum for taste generally seems to be near or slightly below body temperature. The effect is often difficult to assess because of changes in temperature as a solution is put in the mouth. When the tongue and mouth are first adapted to the temperature of the solution, sugar sensitivity increases with temperature, salt and quinine sensitivity decrease, and acid sensitivity remains relatively unchanged.

Taste adaptation (*i.e.*, partial or complete disappearance of taste) may occur if a solution is held in the mouth for a time. In some cases, cross adaptation will occur; *e.g.*, adaptation to one acid may carry over for other acids. Adaptation also may be followed by contrast; *e.g.*, distilled water tastes sweet following exposure to weak acid. Taste masking is an everyday experience; for example, the bitterness of tea and coffee or the sourness of lemonade are masked by sugar or saccharin.

The gustatory difference threshold (or percentage increase in concentration required for a just noticeable difference) is approximately one-fifth (or 20%). At very weak intensities, however, as much as a 100% increase in concentration may be required for a detectable difference.

Food Choice.—Sucking, one of the earliest reflex responses of the infant, can be controlled by gustatory stimuli. Sweet solutions are sucked more readily than is plain water; bitter, salty, or sour stimuli can stop the reflex. Among insects a very specific feeding reaction (proboscis extension) is so automatic that it is widely used as an index of gustatory stimulation. If a fly is held relatively immobile in wax, a drop of sugar solution will elicit proboscis extension when applied to the legs or mouth parts. A fly that has been starved will respond to a weak sugar solution that ordinarily would have no effect. Addition of salt or acid to the solution inhibits this response.

Lower mammals such as laboratory rats, when free to take pure carbohydrates, proteins, vitamins, and minerals from separate containers, will show a consistent pattern of choice that may be modified experimentally. A rat made salt-deficient by removal of the adrenal glands, for example, will increase its sodium chloride intake; normally, adrenalectomy is fatal without salt replacement. Similar effects have been reported in human beings; a dramatic case was that of a child with adrenal pathology who survived for a number of years by spontaneously satisfying his intense craving for salt. However, adult eating habits are much influenced by past experience and may even run counter to physiological requirements. Food habits and fads, cultural conditioning, social usage, and other complex psychological factors play a significant role in eating behaviour (*see* MALNUTRITION).

Toxic substances often are unpalatably bitter, but not all of them have a taste. The rat poison alpha-naphthylthiourea (ANTU) was developed from a relatively insoluble and therefore tasteless form of highly toxic chemical; soluble forms had been rejected by the animals. Lead acetate, sometimes called sugar of lead, is quite poisonous, but was once used as a sweetening agent with disastrous results. Other palatable stimuli also have toxic effects, so that taste alone is not a sure guide to safety.

SENSE OF SMELL

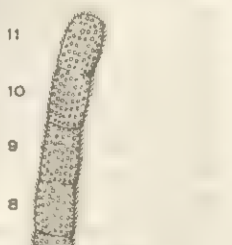
FROM G. H. PARKER, "SMELL, TASTE AND ALLIED SENSES"; REPRODUCED BY PERMISSION OF J. B. LIPPINCOTT CO.

FIG. 3.—SEPARATED SECTION OF OLFACTORY MUCOSA SHOWING SENSE CELLS WITH OLFACTORY HAIRS AND SUPPORTING CELLS

In mammals the olfactory receptors are located in the upper part of the nasal cavity. (*See* also OLFACTORY SYSTEM.) In man, the yellow-pigmented olfactory membrane measures about 2.5 cm.^{2} in each nasal cavity. The olfactory sense cells are long and thin, ending in several delicate hairs that project into and through the mucus covering the nasal epithelium (fig. 3). Electron microscope photographs show from 6 to 12 olfactory hairs per cell. The other end of each cell narrows to a fine nerve fibre that enters the olfactory bulb of the brain through a narrow channel in the bony roof of the nasal cavity. The olfactory area of the rabbit contains about 100,000,000 receptor cells which, with their olfactory hairs, provide a surface equal to the total skin area of the young rabbit. Free nerve endings of the trigeminal supply that mediates common chemical sensitivity are distributed throughout the nasal cavity and olfactory region. They respond to such mild odorants as orange oil as well as such irritants as ammonia.

Odorous molecules are carried to the olfactory mucosa by slight eddy currents during quiet respiration; vigorous sniffing produces a surge into the region. Sensitivity may be impaired by blocked passages, as when nasal membranes are congested.

It is generally agreed that in insects the antennae are the principal olfactory sites, but such appendages as the mouth parts may also participate (fig. 4). The olfactory structures of the honeybee appear to be what are called pore plates (fig. 5), but in some beetles, housefly larvae, and *Drosophila* they are peglike hair derivatives. The stimulus is separated from the neural elements of the peg by a nonliving cuticle with no detectable mucous or other secretion. This is cited as evidence that odour molecules stimulate directly without prior solution in a liquid covering. However, some authorities believe that in vertebrates olfactory stimulation occurs only after the molecules are dissolved in the mucous covering. In spite of differences, a number of studies suggest that odour sensitivity of man and insect are very similar.

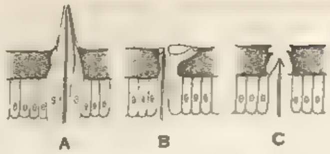


AFTER K. VON FRISCH

FIG. 4.—FEELER OF WORKER BEE: JOINTS 4 THROUGH 11 BEAR OLFACTORY ORGANS

In vertebrates nerve fibres enter the olfactory bulb to end in a series of intricate basketlike clusters called glomeruli. Each glomerulus receives impulses from about 26,000 receptor cells and sends them through 24 mitral cells and 68 tufted cells. Most mitral-cell axons pass into the lateral olfactory tract en route to the olfactory centres at the base of the brain. Most tufted cells cross over to the olfactory bulb of the opposite side. Electrical activity in the primary olfactory nerves, the olfactory bulb, lateral olfactory tracts, and pyriform lobe of the brain have been recorded following odour stimulation. When the bulb is removed, ability to discriminate odours is lost; details of higher olfactory centres were unclear in the 1960s.

Olfactory Qualities.—Most of the great variety of olfactory qualities have been given the names of substances; attempts to classify them have had limited success. One of the best known is that



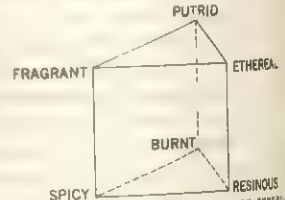
AFTER K. VON FRISCH

FIG. 5.—CROSS SECTION OF OLFACTORY ORGANS ON FEELERS OF INSECTS: (A) OLFACTORY PEG, (B) PORE PLATE, (C) PIT PEG

of H. Henning, who tested more than 400 different scents on people, concluding that there were six main odour qualities: ethereal (fruity), fragrant (flowery), resinous, spicy, putrid (foul), and burnt. Their interrelations could be systematized by a smell prism (fig. 6) based on sensory qualities rather than odorants or basic odour receptors. Electrical activity can be detected readily by wire electrodes inserted into the olfactory bulb. A wavelike response may be recorded from the surface of the bulb and impulse activity is observed that reflects discharges in the mitral cells following stimulation. Those portions of the bulb toward the anterior (or oral) region in the rabbit are most sensitive to water-soluble substances, the more posterior parts being most responsive to fat-soluble odorants.

Use of very fine electrodes shows that specific groups of mitral cells are sensitive to different chemicals. However, these findings fail to show the existence of only a few primary receptors since there is a variety of different combinations of sensitivity. Recordings from the primary receptor nerve fibres show similar patterns of sensitivity. Electrical recording also shows that discharges in the sympathetic nerves to the nasal mucosa instigated by a painful stimulus (*e.g.*, a pinch on the foot of the animal) enhance olfactory sensitivity. This appears to be a reflex that heightens sensory function when the animal is in the presence of danger.

Odorous Substances.—To be smelled, a substance must be volatile enough for its molecules to be carried by air currents. Although chemicals that have both water and fat solubility are often strong odorants, many that are soluble only in water or only in fat lack odour.



S. S. STEVENS (ED.), "HANDBOOK OF EXPERIMENTAL PSYCHOLOGY" (1951); REPRODUCED BY PERMISSION OF JOHN WILEY & SONS INC.

FIG. 6.—H. HENNING'S SMELL PRISM

Only seven of the elements are odorous: fluorine, chlorine, bromine, iodine, oxygen as ozone, phosphorus, and arsenic. Most odorants are organic compounds in which molecular arrangement, structure, and chemical formula are related to odour. Stereoisomers (*i.e.*, different arrangements of the same molecular components) may have different odours; yet a series of benzene derivatives all have a similar odour. The earliest known benzene derivatives (*e.g.*, oil of wintergreen, oil of anise) prompted chemists to call the whole class aromatic compounds (*see* BENZENE; ISOMERISM).

The scent of flowers and roots depends on minute quantities of highly odorous essential oils. Although the major odorant constituents can be identified by chemical analysis, botanical essences are so complex that their odours can be duplicated only by adding them in small amounts to synthetic formulations.

Odour Sensitivity.—In spite of the relative inaccessibility of the olfactory end organs, they are estimated to be 10,000 times more sensitive than taste buds. For example, ethyl mercaptan is reported detectable at a concentration of 4×10^{-8} mg. per litre of air. A just noticeable difference in intensity may appear with a 20% increase in odorant strength; at low concentrations as much as 100% increase may be required. Temperature and humidity influence the strength of an odour by affecting volatility. Hunting dogs follow a trail better when humidity is high since evaporation and dissipation of the odour are retarded. In perfumes (*q.v.*) fixatives are used to retard evaporation of the more volatile constituents. The temporary anosmia (lack of olfactory function) following colds in the nose may be complete or partial; in the latter case only the odours of certain substances are involved. Paranosmia (change in perceived odour quality) also may occur. Changes in sensitivity are said to occur during the menstrual cycle, particularly with odorants related to steroids and sex hormones. Also, olfactory acuity is said to become more acute during hunger.

The stench of the slaughterhouse or chemical laboratory ceases to be noticeable after a few minutes. Such olfactory adaptation, as measured by a rise in threshold, is greater with stronger odours. Cross adaptation also is observed; thus eucalyptol may be difficult to detect after adaptation to camphor. Adaptation long was regarded as the result of changes in the receptor; however, peripheral receptors do not seem to adapt. Rhythmic electrical discharges in the olfactory bulb persist long after the experimenter fails to detect the odour that is stimulating the experimental animal. Apparently olfactory adaptation is mediated partially in the brain.

Odour Blending and Flavour.—The ancient art of perfumery and the modern techniques of odour control rest on mixing and blending. Two different odours presented at once may be readily identifiable. The more they resemble each other, the greater will be the tendency to blend, yet trained workers usually can discriminate the components of a successfully blended perfume. The substantially greater intensity of one odour may mask another. Masking and chemical neutralization are the commonest bases for odour control; air may be deodorized by passing it through activated charcoal (*see* DEODORIZER).

The distinctive flavours of food are known largely through the sense of smell. Flavour is the composite of experiences from many senses, but the aroma of roast beef and the delicate bouquet of wine are olfactory in origin. Flavour technology assumes an ever-increasing place in the food industry; it is common for flavour panels of several trained members to judge the flavour of new food products. Using psychophysical methods with adequate statistical control, such panels are highly reliable and can detect qualities so subtle that they defy the methods of physics and chemistry. In using large, untrained consumer panels the emphasis is on acceptability, often a hedonic or emotional reaction to the product. Such judgments are unstable and may vary among individuals because of idiosyncrasy or differences in experience. The strong cheese odour so palatable to the gourmet can produce revulsion in the uninitiated (*see* FLAVOUR; FOOD PREPARATION).

Effects on Behaviour.—Recognition of friend or foe by social insects may depend on olfactory cues: certain ants attack their own kind furiously if deprived of the sense of smell by amputation of their antennae; bees entering a strange hive are put to death because the scent of a foreign hive clings to them. Bees also have an organ on the end of the abdomen that deposits a scent to mark newly discovered food sources, and guide foraging workers. The scents of flowers attest to the evolutionary importance of odour; those flowers that attract insects most efficiently are the likeliest to be pollinated and to continue the botanical species (*see* SCENTED PLANTS).

The effect of odours on sexual behaviour of invertebrates is most striking; a female moth was observed to attract more than 100 males during relatively brief observation periods of 6½ hours. The remarkable difference in antennal development between the male and the female moth is shown in fig. 7. Mammals in the wild state appear to use their odour glands for sexual attraction. Laboratory rats show preference for the arm of a maze scented with the odour of a sexually receptive female. It is possible that some rudiments of these effects operate in man. The most sexually provocative perfumes have a high proportion of musk or musklike odour. Genuine musk is derived from glands of the musk deer and is chemically related to human sex hormones; recall also that odour sensitivity in humans varies with the menstrual cycle. Further study of these effects in man is needed to understand many aspects of smell and taste familiar in everyday life.

SMELLIE, WILLIAM (1697–1763), "the master of British midwifery," was born at Lanark in 1697. In 1739 he went to London, where in 1741 he began to teach midwifery by lecture-demonstrations for midwives and medical students. One reason for his success was that he attended poor women free of charge on condition that his students were allowed to watch. He thus broke the female monopoly in midwifery, and medical men (men midwives) began to be called in to attend childbirth.

Smellie invented (simultaneously with A. Levret of Paris) the "long" obstetric forceps, but his immortal contribution was his discovery and lucid description of "the mechanism of labour" (*i.e.*, the way in which the child's head adapts itself to the changes in shape and dimensions of the bony pelvic canal during birth). He retired to Lanark and died there on March 5, 1763.

Smellie's teaching was embodied in his *Treatise on the Theory and Practice of Midwifery*, 3 vol. (1752–64), and *A Set of Anatomical Tables* (1754).

BIBLIOGRAPHY.—Smellie's *Treatise*, ed. with a memoir by A. H. McClintock, New Sydenham Society, 3 vol. (1876–78); J. Glaister, *Dr. William Smellie and His Contemporaries* (1894); R. W. Johnstone, *William Smellie, the Master of British Midwifery* (1952).

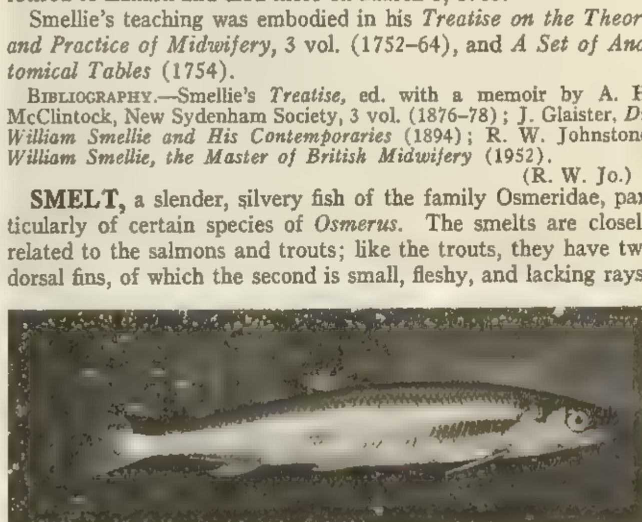
SMELT, a slender, silvery fish of the family Osmeridae, particularly of certain species of *Osmerus*. The smelts are closely related to the salmons and trouts; like the trouts, they have two dorsal fins, of which the second is small, fleshy, and lacking rays;



W. T. DAVIDSON FROM NATIONAL AUDUBON SOCIETY

AMERICAN SMELT (OSMERUS MORDAX)

the ventral fins are attached below the first dorsal fins. They are chiefly cold-water fishes confined to the northern hemisphere.

The American smelt (*Osmerus mordax*) ranges along the shores from Virginia to eastern Labrador and has become naturally landlocked in many lakes and ponds of the northeastern U.S. and Canada. They were introduced in 1912 into Crystal Lake, Mich., from where they spread throughout the Great Lakes, becoming an important commercial species. Whether smelt are marine or landlocked, they come in to shore in late winter and spring and run for short distances upstream to spawn. The small, sticky eggs cluster and adhere to any object which they touch; they hatch in 8 to 30 days. The American smelt may grow to be 14 to 15 in. long, but most adults are usually smaller. The European smelt (*O. eperlanus*), ranging from Scandinavia to the English Channel, is similar in appearance and habits to the American form.

Several closely related species occur in the North Pacific region. These include the rainbow herring (*Osmerus dentex*), the surf smelt (*Hypomesus pretiosus*), the Kodiak smelt (*Thaleichthys albatrossis*), and the eulachon or candlefish (*Thaleichthys pacificus*). A number of unrelated small fishes somewhat resembling osmerids externally are also called smelt in various parts of the world.

In the United States commercial fishermen take almost 11,000,000 lb. of smelts annually, and amateurs take an unknown but large additional quantity. More than 70% of the total is from the Great Lakes, a large part of the remainder from the Pacific Coast, and about 1% from New England.

See also FISH: *Survey of the Bony Fishes*. (L. A. WD.)

SMELTING: *see* METALLURGY.

SMERDIS (6th century B.C.), the generally accepted Greek form of name originally given by Herodotus to Bardiya, son of Cyrus the Great of Persia and brother of Cambyses (*q.v.*). According to Xenophon, Cyrus on his deathbed appointed him governor of Media, Armenia, and Cadusia (Gilan). Murder and intrigue have made the true facts of Smerdis' life extremely obscure. According to one theory he was murdered by Cambyses (before Cambyses went to Egypt), presumably because he feared Smerdis might rebel in his absence. The murder was kept secret and Smerdis was successfully impersonated by Gaumata, a Magian, who seized the throne in March 522 B.C. while Cambyses was still in Egypt. He was acknowledged as king in Persia, Media, and the other provinces. In September, after the death of Cambyses, Darius I (*q.v.*), with the help of six associates, killed Gaumata and seized the throne.

This account, given by Darius in his inscription at Bisitun, is in the main followed by Herodotus, Ctesias, and other Greek authors. Contemporary Aeschylus, however, believed that King Smerdis (whom he calls Mardos) really was the legitimate heir (*Persae*, 774–776). This belief is shared by some modern scholars who take the view that Darius, not Cambyses, murdered Smerdis and invented the story of Gaumata to justify his action.

Whoever King Smerdis may have been, he did, according to Herodotus, confer great benefits on his subjects, granting them freedom from military service and tribute for three years, so that his death was greatly mourned. Darius also acknowledges his hold on the people but ascribes it to fear of his tyranny and accuses him of the destruction of temples and wholesale confiscation of property. His death was annually celebrated in Persia by a feast called "The Killing of the Magian," at which no Magian was allowed to appear.

In 521 B.C. a certain Vahyazdata, taking advantage of the confusion, rose against Darius and also claimed to be Smerdis the son of Cyrus. He gained considerable support and sent an army into Arachosia (Kandahar province), but was finally defeated and slain. (J. M. M.-R.)

SMET, PIERRE JEAN DE (1801–1873), Belgian Jesuit, known throughout the western United States as the Indians' truest friend, was born at Termonde, Belg., in 1801. He sailed to the United States in 1821 to enter the Society of Jesus, and was ordained priest in 1827 at St. Louis University in Missouri, his headquarters for life. During 40 years he crossed the Atlantic 19 times, visiting European cities and courts to beg funds, equipment, and recruits for the university and Indian missions. He founded his first mission in Iowa (1838). In negotiating peace between the Sioux and Potawatomi his unusual power over Indians was revealed. For 30 years, having their complete confidence, he was welcomed among all tribes. He helped pacify the Plains Indians in 1841; in 1863, when he went alone to avert a Sioux attack; and in 1868, when he induced Sitting Bull to negotiate. He arranged peace in the Pacific northwest in 1851 and, as United States commissioner with Gen. William S. Harney, again in 1858. Ever outspoken for Indian rights and against punitive expeditions, De Smet won ready consent to establish Christian missions and send teachers. Between sea voyages and western travels totaling 180,000 mi., he published three books in four languages. His vigorous and winning personality made friends of statesmen, pioneers, traders, and soldiers. He died in St. Louis, May 23, 1873.

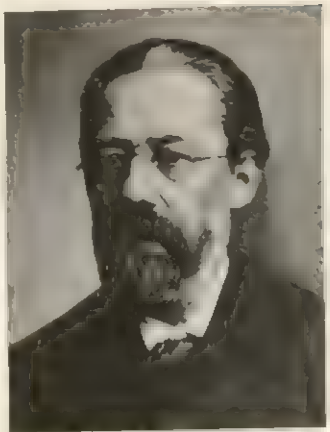
SMETANA, BEDŘICH (1824–1884), Czech composer of operas and symphonic poems, founder of the Czech national school of music. Born at Leitomischl (Litomyšl) in eastern Bohemia on March 2, 1824, he studied the piano in his youth with Josef Proksch and later became music teacher to the family of Count Leopold Thun. Encouraged by Liszt, he opened a piano school in Prague in 1848 and the following year married the pianist Katharina Kolař. In 1856 he wrote his first symphonic poems and in the same year was appointed conductor of the philharmonic society of Göteborg (Sweden), where he remained until 1861. He then returned to Prague where he played the leading part in the establishment of the national opera house.



ARCHIV FÜR KUNST UND GESCHICHTE, BERLIN

BEDŘICH SMETANA

Smetana's first opera, *Braniboři v Čechách* ("The Brandenburgers in Bohemia"), was produced in Prague in 1866. This was followed by the production on May 30, 1866, of his second opera, *Prodaná nevěsta* ("The Bartered Bride"), which later established Smetana's reputation as a distinctively Czech composer throughout Europe and the U.S. His later operas were less successful. *Dalibor*, written under the influence of Wagner, was given in 1868. *Libuše*, named after a legendary figure in the history of Prague and intended to celebrate the projected coronation of the emperor Francis Joseph I as king of Bohemia, was not given until 1881, when its production marked the opening of a new opera house at Prague. In 1874 Smetana resigned his conductorship of the Prague Opera and later in the year became totally deaf. Between 1874 and 1879, however, he wrote some of his finest works, notably the cycle of six symphonic poems bearing the collective title *Má vlast* ("My Country") and the string quartet to which he gave the title *Zmého života* ("From My Life"). *Hubička* ("The Kiss") was successfully produced in 1876, but *Čertova stěna* ("The Devil's Wall"), given in 1882, shows signs of declining powers. Following attacks of depression and symptoms of mental instability, Smetana entered an asylum at Prague and died there on May 12, 1884. The Smetana Society, founded in Prague in 1931, maintains a museum containing the composer's manuscripts and other documents, and sponsors the publication and performance of his works.

SMETHWICK, a municipal county, and parliamentary borough, Staffordshire, Eng., adjoining Birmingham 3½ mi. NW. Pop. (1961) 68,390. Area 3.9 sq.mi. The borough was incorporated in 1899, became a county borough in 1907, and a parliamentary borough in 1918. It returns one member. It was mentioned in Domesday Book as "Smedewich." The historic inventions of Matthew Boulton, James Watt, and William Murdock (*qq.v.*) had their origin in the Soho foundry at Handsworth which was partly removed to Smethwick in 1848. The town has since become known for its glass works and there are manufactures of lighthouse apparatus, iron and steel, and a variety of metal hardware.

SMETONA, ANTANAS (1874–1944), Lithuanian statesman and journalist who in 1919 became the first president of Lithuania and later returned to power as an authoritarian head of state for the last 13 years of his country's independence. Born on Aug. 10, 1874, in the Ukmergė district, under Russian rule, Smetona studied law at St. Petersburg, graduating in 1902. He edited the first Lithuanian daily, *Vilniaus Žinios*, and the Democratic Party's organ, *Lietuvos Ūkininkas*. In 1905 he was elected to the presidium of the Vilnius diet, which proclaimed Lithuanian autonomy. From 1907 to 1913 he edited the journal *Viltis*; and in 1913 he founded *Vairas*, later the organ of the Nationalist Party.

On the convocation of the *Lietuvos Taryba*, or Council of Lithuania, during the German military occupation of the country in World War I, Smetona was unanimously elected its president in September 1917; and from April 1919 to June 1920 he was president of the newly proclaimed state. In 1921 he served as chairman of the Lithuanian delegation at Riga for the settlement of the Latvian-Lithuanian boundary dispute; and early in 1923 he was authorized to negotiate with the Allies during the crisis over Memel (Klaipėda). In 1923 also he became lecturer on philosophy in the newly established university in Kaunas.

After the military *coup d'état* of Dec. 16–17, 1926, organized

by a Nationalist group and backed by the Christian Democrats, Smetona was elected president of the Lithuanian republic. He was reelected in 1931 and in 1938, but on June 15, 1940, when Lithuania was occupied by Soviet forces, he fled to Germany and thence, in March 1941, to the United States. He died in a fire at Cleveland, O., on Jan. 9, 1944. *See* also LITHUANIA: *History*. (MA. G.)

SMIBERT (SMYBERT), **JOHN** (1688–1751), British-American portrait painter, one of the first well-trained artists to work in the American colonies, was born in Edinburgh, March 24, 1688, and apprenticed to a house painter. He went to London about 1709 to study art and worked there, except for a three-year visit to Italy, until 1728. In that year he accompanied George Berkeley (*q.v.*) to Rhode Island as prospective professor of fine arts in the college which Berkeley hoped to establish in Bermuda. When this project failed, he went in 1730 to Boston, Mass., where he married and spent the rest of his life. He painted many prominent Bostonians, but had to supplement his income by keeping a shop, where he sold art supplies and prints. His collection of copies from the "old masters" was unique in colonial America and influenced the development of several later artists, notably Copley and Allston. In 1742 he drew the plans for Faneuil Hall, Boston. He died in Boston, April 2, 1751. His best-known work is "Bishop Berkeley, Family and Friends" (1729, Yale University), which contains a self-portrait of the artist. Many of his single portraits are exhibited in American museums and historical societies. (D. H. W.)

SMILES, SAMUEL (1812–1904), Scottish author best known for his didactic work *Self-Help* (1859), which with its successors, *Character* (1871), *Thrift* (1875), and *Duty* (1880), enshrined the basic Victorian values associated with the "gospel of work." He was born at Haddington, Berwickshire, on Dec. 23, 1812. One of 11 children left fatherless in 1832, he early learned the meaning of self-reliance. Although he qualified in medicine at Edinburgh in 1832, he soon abandoned medical practice for journalism, moving to Leeds, where from 1838 to 1842 he edited the radical *Leeds Times*. His radicalism had much in common with that of Ebenezer Elliott and Joseph Hume (*qq.v.*), and, like them, he was a zealous advocate of material progress based on individual enterprise and free trade. From 1845 to 1866 he was engaged in railway administration, and in 1857 he published a life of George Stephenson. He followed this with *Self-Help: With Illustrations of Character and Conduct*, the outcome of a series of lectures on self-improvement given to young men in Leeds; 250,000 copies had been sold by the end of the century and it was widely translated. Smiles wrote many other books, including *Lives of the Engineers* (three volumes, 1861–62; five-volume enlarged edition, 1874), a pioneer study in economic history; and an *Autobiography* (edited by T. Mackay, 1905). He died in Kensington, London, on April 16, 1904.

See Self-Help, with introduction by Asa Briggs (1958); T. B. Green, *The Life and Work of Dr. Samuel Smiles* (1904). (A. BRI.)

SMILLIE, the name of a family of U.S. painters, engravers, and etchers.

JAMES SMILLIE (1807–1885), engraver, was born in Edinburgh, Scot., on Nov. 23, 1807, and emigrated to New York in 1829. He was a landscape line engraver of some distinction, the best known of his numerous works being a series of large plates after Thomas Cole's "The Voyage of Life." After 1861 he devoted his time to the engraving of bank notes. He died on Dec. 4, 1885.

JAMES DAVID SMILLIE (1833–1909), his eldest son, an engraver, etcher, and painter, was born on Jan. 16, 1833, in New York City. He studied with his father and at the National Academy of Design. His work includes engraved steel vignettes for bank notes and some illustrations, notably F. O. C. Darley's pictures for Dickens' and Cooper's novels. He was elected an associate of the National Academy in 1865—the year after he first began painting—and an academician in 1876, and was a founder (1866) of the American Water Color Society and of the New York Etching Club. Smillie's most significant works are his etchings, dry points, and aquatints, which show complete technical mastery. He died on Sept. 14, 1909.

GEORGE HENRY SMILLIE (1840–1921), younger son of James Smillie, was a landscape painter. Like his brother, he first studied with his father; later he was a pupil of James MacDougal Hart. He, too, was a member of the National Academy of Design and of the American Water Color Society. Smillie's best-known work probably is the "Lake in the Woods," first shown at the National Academy in 1872. He died Nov. 10, 1921.

SMITH, ADAM (1723–1790), Scottish political economist and philosopher, whose book *The Wealth of Nations* exerted the greatest influence on subsequent economic and political theory and practice, was the son of the comptroller of the customs at Kirkcaldy, Fife, Scot. The exact date of his birth is unknown, but he was baptized at Kirkcaldy on June 5, 1723, his father having died some six months previously. In 1737 he proceeded to Glasgow university, studying moral philosophy under "the never-to-be-forgotten" Francis Hutcheson (as Smith called him). In 1740 he entered Balliol college, Oxford, but as William Robert Scott has said, "the Oxford of his time gave little if any help towards what was to be his lifework," and he withdrew from the college in 1746. In 1748 he began delivering public lectures in Edinburgh under the patronage of Lord Kames. Some of these dealt with rhetoric and belles-lettres, but later he took up the subject of "the progress of opulence," and it was then, in his middle or late 20s, that he first expounded the economic philosophy of "the obvious and simple system of natural liberty" which he was later to proclaim to the world in his *Inquiry into the Nature and Causes of the Wealth of Nations*. About 1750 he met David Hume, who became one of the closest of his many friends.

In 1751 Smith was appointed professor of logic at Glasgow university, transferring in 1752 to the chair of moral philosophy. His lectures covered the field of ethics, rhetoric, jurisprudence and political economy, or "police and revenue." In 1759 he published his *Theory of Moral Sentiments*, embodying some of his Glasgow lectures. This work, which established Smith's reputation in his own day, is concerned with the explanation of moral approval and disapproval. His capacity for fluent, persuasive, if rather rhetorical argument is much in evidence. He bases his explanation, not as the third Lord Shaftesbury and Hutcheson had done, on a special "moral sense," nor, like Hume, to any decisive extent on utility, but on sympathy. There has been considerable controversy as to how far there is contradiction or contrast between Smith's emphasis in the *Moral Sentiments* on sympathy as a fundamental human motive, and, on the other hand, the key role of self-interest in *The Wealth of Nations*. In the former he seems to put more emphasis on the general harmony of human motives and activities under a beneficent Providence, while in the latter, in spite of the general theme of "the invisible hand" promoting the harmony of interests, Smith finds many more occasions for pointing out cases of conflict and of the narrow selfishness of human motives.

Smith now began to give more attention to jurisprudence and political economy in his lectures and less to his theories of morals. An impression can be obtained as to the development of his ideas on political economy from the notes of his lectures taken down by a student in about 1763 which were later edited by E. Cannan (*Lectures on Justice, Police, Revenue and Arms*, 1896), and from what Scott, its discoverer and publisher, describes as "An Early Draft of Part of *The Wealth of Nations*," which he dates about 1763.

BY COURTESY OF THE NATIONAL GALLERIES OF SCOTLAND

ADAM SMITH, PASTE MEDALLION BY JAMES TASSIE, 1787

At the end of 1763 Smith obtained a lucrative post as tutor to the young duke of Buccleuch and resigned his professorship. From 1764–66 he traveled with his pupil, mostly in France, where he came to know such intellectual

leaders as Turgot, D'Alembert, André Morellet, Helvétius and, in particular, François Quesnay, the head of the Physiocratic school (*q.v.*) whose work he much respected. On returning home to Kirkcaldy he devoted much of the next ten years to his magnum opus, which appeared in 1776. In 1778 he was appointed to a comfortable post as commissioner of customs in Scotland and went to live with his mother in Edinburgh. He died there on July 17, 1790, after a painful illness. He had apparently devoted a considerable part of his income to numerous secret acts of charity.

Shortly before his death Smith had nearly all his manuscripts destroyed. In his last years he seems to have been planning two major treatises, one on the theory and history of law and one on the sciences and arts. The posthumously published *Essays on Philosophical Subjects* (1795) probably contain parts of what would have been the latter treatise.

The Wealth of Nations.—It is on *The Wealth of Nations* that Smith's renown securely rests. This work, in the first place, with those of Sir William Petty, Richard Cantillon, Quesnay and Turgot, did most to create the subject of political economy and develop it into an autonomous systematic discipline; and secondly, in the western world, it is the most influential book on the subject ever published. In the plan of Smith's lifework, however, it seems that *The Wealth of Nations* had represented only one section of a comprehensive system of moral or social philosophy, in which he had intended to survey and explain the progress of society in all its aspects.

Controversial views have been expressed as to the extent of Smith's originality in *The Wealth of Nations*. However, it seems justifiable to regard him neither as the original and almost unique creator or founder of political economy, nor, on the other hand, as a completely unoriginal systematizer, deeply indebted in particular to Turgot and Quesnay. A survey of the influences on, or ingredients of, Smith's work would almost amount to a history of the economic thought of the century or more before his time. In his general philosophical approach Smith continued the tradition of the "natural law" school of Hugo Grotius and Samuel von Pufendorf, and in the broad layout of his ideas started from his Glasgow predecessors Gershom Carmichael and, above all, Francis Hutcheson. Hume must have helped in strengthening and developing his liberal ideas, and Montesquieu his historical approach. His English predecessors, Petty, John Locke, Bernard Mandeville, Joseph Harris and Sir James Steuart, must also have been of some help.

The Wealth of Nations is a work of much wider sweep than its 19th-century successors, much wider even than *The Principles of Political Economy* by John Stuart Mill. Above all, it is marvelously rich in learning about earlier periods as well as acute in its observation of the contemporary scene. It is also a great work of political philosophy, most eloquently and persuasively delivered. As regards the economic analysis and theorizing, this provides a fairly loose and slender thread, not usually at all rigorously worked out and occurring mostly in the first two books. Nevertheless, *The Wealth of Nations*, rambling and prolix though it often is, did systematize its subject, with enormous gains to its public influence. Its five books are surveyed below:

Book I: The Division of Labour, Value and Distribution.—"The annual labour of every nation is the fund which originally supplies it with all the necessaries and conveniences of life" is Smith's opening sentence, and it enunciates, with its primary emphasis on the "real" productivity of labour, one of the leading themes of the work. Increasing the productivity of labour requires, above all, its specialization or "division," on which Smith places extreme emphasis as the key to economic progress. The division of labour is limited by the extent of the market, but, as exchanges multiply and ramify, money as a medium of exchange is required, and there arise the problems of the values and prices of goods and services. In these opening five chapters Smith pursues a now well-worn sequence of ideas, than which there is no more lucid or logical way of leading into the central problems of economics or social economy.

Smith begins his treatment of value with the distinction between value in exchange and value in use, or "utility," and drives this distinction so far as to proclaim that value in use is not necessary even for "the greatest value in exchange." After setting out, without keeping clearly separate, the concepts of the labour commanded by a good, the toil and trouble of commanding a good, and the labour contained in it, and having laid down labour as a measure or standard of value, he settles for an explanation of "natural" prices in terms of cost of production, made up of wages, profit and rent. Smith's distinction between "natural" and "market" prices established a pattern of analysis followed out by the main 19th-century theories of value and price. Natural price is the "long-run" competitive equilibrium price determined by cost of production, while market price is the "short-run" price, determined by supply and demand. Natural price consists of wages, rent and profits at their "natural" levels. As regards wages, these will tend in a stationary economy to a subsistence level, though they will remain above subsistence in a progressive economy. Smith emphasizes the stronger bargaining position of combinations of employers as against the workers, and also suggests the idea behind the later "wages fund" doctrine that wages are an advance by the employer to maintain the worker while his product is ripening. He distinguishes profit as a separate income by marking it off from wages of "inspection and direction," and he notes the element of compensation for risk. He argues that through increasing competition the rate of profit will tend to fall as an economy progresses toward the stationary state. On rent Smith's position is rather ambiguous, and his chapter on the subject includes a vast digression on variations in the value of silver. His explanation mentions the element of monopoly, as well as the productivity of land, and he argues that rent enters into price "in a different way from wages and profit," since "high or low wages and profit are the causes of high or low price; high or low rent is the effect of it"—thus anticipating David Ricardo's theory. Book I ends with an analysis of the effects of economic progress on wages, profits and rents—the incomes, that is, of the "three great, original and constituent orders of every civilized society, from whose revenue that of every other order is ultimately derived." Smith's analysis provided the pattern for subsequent important attempts on this subject, though the precise logic of his model is not entirely clear.

Book II: Capital, Saving and Investment.—The title of the second book is "Of the Nature, Accumulation, and Employment of Stock," the term "stock" including consumers' capital, as well as producers' capital, which latter is capital in Smith's sense. He classifies capital into fixed and circulating, each with four subbranches. He includes money as a part of the circulating capital of society, but not explicitly the means of subsistence advanced to productive labourers. In a long chapter on money, "the great wheel of circulation, the great instrument of commerce," he explains the saving to the economy which arises from the development of banking and paper money in place of the precious metals.

Smith comes next to his definitions of "productive" and "unproductive" labour, in which he is attempting to adapt the peculiar definition of the Physiocrats according to which only agricultural labour was "productive." Smith's distinction seems little more helpful for modern analysis, since he defines services—though not retailing—as unproductive, "how honourable, how useful, or how necessary soever" they may be. There follows Smith's theory of saving and investment, or that saving *is* investment. This lays unqualified emphasis on the universal and inevitable beneficence of "parsimony," or private voluntary saving, as "the immediate cause of the increase of capital," since, for any income-receiver, "that portion which he annually saves, as, for the sake of the profit, it is immediately employed as a capital, is consumed in the same manner" as what he spends on his consumption. Hence "every frugal man is a public benefactor," since, apparently, for every individual decision to save there is a corresponding decision to invest.

Joseph Schumpeter has pointed out the immense influence over the next century and a half of this analysis. It is very similar to that of Turgot's published ten years previously in his *Réflexions*, though Smith elaborates its implications, especially for policy, much more emphatically. The Turgot-Smith theory swept away

the rudimentary analysis of effective demand of their predecessors as well as Quesnay's reservations regarding the inevitable beneficence of saving.

Smith's analysis of saving and investment, implying the utilization of all income for consumption or investment spending, formed the basis for important parts of his attack (notably in the first chapter of book iv) on what, following Physiocratic usage, he called "the mercantile system," for its preoccupation with monetary policies and "the popular notion that wealth consists in money." There Smith argues that "it is not for its own sake that men demand money" which "can serve no other purpose besides purchasing goods." Complaints of a general scarcity of money are wrongheaded, for "though a particular merchant, with abundance of goods in his warehouse, may sometimes be ruined by not being able to sell them in time, a nation or country is not liable to the same accident . . . It might, indeed, suffer some loss and inconveniency, and be forced upon some of those expedients which are necessary for supplying the place of money. The annual produce of its land and labour would be the same or very nearly the same."

Smith's theory of saving and investment is also an essential part of his general campaign for reliance on the invisible hand of the individualist profit motive as against state action. For, as he argues when discussing tariffs, "no regulation of commerce can increase the quantity of industry in any society beyond what its capital can maintain. It can only direct a part of it into a direction which it might not have gone." The same system of ideas pervades, also, his final chapter of book iv, "Of Public Debts," with its underlying assumption that all government expenditure is "unproductive." However, perhaps in contrast with his extremely emphatic and influential analysis of saving and investment, Smith favoured a legal maximum rate of interest rather than complete freedom. Nevertheless, what John Maynard Keynes was to call "the classical system of ideas" first emerged fully developed in *The Wealth of Nations*. The "law of markets" of Mill and Jean Baptiste Say, and what came to be known in Great Britain in the 1920s and 1930s as "the Treasury view," that government expenditure could do little or nothing to raise the level of employment, are traceable, above all, to Adam Smith.

Book III: "Of the Different Progress of Opulence in Different Nations."—This is probably the oldest part of the work, deriving from Smith's Edinburgh lectures. It forms an interlude on the course of economic development as it proceeds by the exchange of goods and services between town and country or manufacturing and agriculture, and it is illustrated by a selective survey of European economic history. Smith argues for a "natural course of things," according to which "the capital of every growing society is, first, directed to agriculture, then to manufacture, and lastly to foreign commerce." Any other order is "unnatural and retrograde." Indeed, it is in agriculture that the investment of a given capital is most advantageous to society. Over much of Europe, though fortunately not to the same extent in Britain, pernicious legislation with regard to land tenure and primogeniture, and internal obstructions and export prohibitions on the corn trade, have distorted the natural order and prevented the invisible hand from harmonizing the private and social gains from investment.

Book IV: "Of Systems of Political Economy".—This is devoted to Smith's attack on "the mercantile system" in the framework of a general review of commercial policies. It concludes with a critical but friendly chapter on "the agricultural system" of the Physiocrats. Smith's most definitely identifiable target was the existing mass of restrictive regulations and monopolistic institutions, practices and privileges, in fact, all those "systems either of preference or of restraint" which "being thus completely taken away, the obvious and simple system of natural liberty establishes itself of its own accord." He has already argued for free choice of occupations by the removal of apprenticeship restrictions and settlement laws, and for free trade in land by the abolition of primogeniture and entails. In book iv he calls, of course, for internal free trade, which he recognizes as a vital factor in the economic progress of Britain as contrasted with France. Most important are his weighty and detailed case for freedom in international trade and his attacks on duties, bounties and the monopolistic privileges of the chartered companies. However, he makes certain concessions regarding restrictions in special circumstances on the export of corn, a moderate export tax on wool and moderate import duties on manufactures where these might yield "a considerable advantage" to a country's own industries, though he will give no protection to infant industries as such. Smith argues for gradualness or "a good deal of reserve and circumspection" in the removal of restrictions, where considerable unemployment might be caused, and says that to expect that complete free trade should ever be established in Great Britain is Utopian.

It is in book iv that Smith introduces several of his most famous passages advocating the free play of self-interest: "As every individual, therefore, endeavours as much as he can both to employ his capital in the support of domestic industry, and so to direct that industry that its produce may be of the greatest value; every individual necessarily labours to render the annual revenue of the society as great as he can. He generally, indeed, neither intends to promote the public interest, nor knows how much he is promoting it. By preferring the support of domestic to that of foreign industry, he intends only his own security; and by directing that industry in such a manner as its produce may be of the greatest value, he intends only his own gain, and he is in this, as in many other cases, led by an invisible hand to promote an end which was no part of his intention. Nor is it always the worse for the society that it was no part of it. By pursuing his own interest he frequently promotes that of the society more effectually than when he really intends to promote it."

In his very striking chapter "Of Colonies" Smith campaigns against all nationalistic and monopolistic restrictions on colonial trade, claiming that these benefit only a small minority and not the broad masses of the nation. Because of the burden of defense "under the present system of management, therefore, Great Britain derives nothing but loss from the dominion which she assumes over her colonies." After a searching discussion of political relationships he suggests the vision of a free-trade association of politically independent partners, in which the mother country and its colonies would become "faithful, affectionate, and generous allies."

Book V: "Of the Revenue of the Sovereign or Commonwealth."—This deals with the expenditure (or functions) of the state and with taxation and public debts. Smith confines the role of the state to three heads: (1) defense (which in a famous aside approving the Navigation acts he had declared to be "much more important than . . . opulence"); (2) justice and civil government, particularly "the defence of the rich against the poor"; and (3) that of "erecting and maintaining those public institutions and those public works, which, though they may be in the highest degree advantageous to a great society, are, however, of such a nature, that the profit could never repay the expense to any individual or small number of individuals." This third heading could, of course, be a most capacious one. Smith specifically mentions the provision of roads, bridges, canals, harbours and, to some extent, education as duties of the state. He discusses further possibilities such as banks, his main criterion being that any state enterprise should pay its way. He emphasizes that what the state may beneficially take on is relative to the efficiency and standards of the government of the day, and he expresses a low view of the capacities of the contemporary British government; however, he has an equally unfavourable opinion of the efficiency of most joint stock companies. Previously he had enunciated as a principle (which might legitimatize an almost indefinite extension of governmental intervention) that "those exertions of the natural liberty of a few individuals which might endanger the security of the whole society, are, and ought to be, restrained by the laws of all governments." As regards taxation, Smith favours proportionality, along with certainty, convenience and economy, though later he claims that "it is not very unreasonable that the rich should contribute to the public expense, not only in proportion to their revenue, but something more than in that proportion."

Though Smith's main treatment of the functions of government comes in book v, various suggestions for beneficent state action are scattered throughout *The Wealth of Nations*. As J. Viner has

pointed out, Smith never collected his full program together and, indeed, probably omitted to mention some kinds of state activity which he would heartily have favoured, such as some sort of provision for the destitute or unemployed. So state action emerges as an exception, which is to be assumed guilty until proved innocent or beneficent, while private initiative is to be assumed beneficent until proved guilty. Taken together, his considerable exceptions might build up into a very large role for the state, though, unlike his predecessors and his successors since Keynes, he held rigidly that the state neither could nor should seek to control the aggregate level of activity and employment. Indeed it was the sweep and force of Smith's advocacy of the simple system of natural liberty which gave *The Wealth of Nations* its revolutionary influence and which constituted its great message for succeeding generations: "All systems either of preference or of restraint, therefore, being thus completely taken away, the obvious and simple system of natural liberty establishes itself of its own accord. Every man, as long as he does not violate the laws of justice, is left perfectly free to pursue his own interest his own way, and to bring both his industry and capital into competition with those of any other man, or order of men. The sovereign is completely discharged from a duty, in the attempting to perform which he must always be exposed to innumerable delusions, and for the proper performance of which no human wisdom or knowledge could ever be sufficient; the duty of superintending the industry of private people, and of directing it towards the employments most suitable to the interest of the society." At the same time *The Wealth of Nations* provided a first great survey of economic life in all its interdependence, and a framework for the development of political economy as a separate discipline.

For a modern edition of *The Wealth of Nations* see that of E. Cannan, 2 vol., 6th ed. (1950). *See* also *The Theory of Moral Sentiments*, 6th ed. (1790); and *Essays on Philosophical Subjects*, new ed. (1872).

SMITH, ALFRED EMANUEL (1873–1944), U.S. politician and governor of New York state, was born in New York city on Dec. 30, 1873, in the Old Fourth ward under the Brooklyn bridge, of poor but respectable parents. Upon the death of his father, who had been a rather unsuccessful truckman, in 1886, Smith's education at St. James's parochial school, near his home, was interrupted. Forced to help support his mother and sister, the boy held a variety of jobs and finally became a checker at the Fulton fish market, where he remained for seven years. Even as a small boy Smith had given indications of talent in elocution and amateur dramatics, and, despite long hours at work, he continued his interest in theatricals and at one time considered a stage career.

ALFRED E. SMITH

Smith's political career began in 1895 when the Tammany district leader made him an investigator in the office of the city commissioner of jurors, with a salary of $800 a year. In the autumn of 1903 he was elected to the New York state assembly on the Democratic ticket. He went to Albany, N.Y., with little formal education but with an alert mind and an intimate knowledge of the city district he represented. He served continuously from 1904 to 1915. By 1913 he had become speaker of the assembly, an office second only to that of governor in power. During his first ten years in the legislature Smith gave small indication of the political independence he was to show later as governor. Industrious and intelligent, he was nevertheless a routine politician who obeyed the orders of Charles F. Murphy the Tammany Hall "boss." After 1911, however, his viewpoint was broadened through his appointment to a commission which investigated factory conditions. In 1915 he was sent as a delegate to the constitutional convention held at Albany to revise the state's fundamental law.

Tammany Hall rewarded Smith in 1915 by making him sheriff of New York county. In 1917 he was elected president of the board of aldermen of Greater New York. The following year he resigned to run for governor against Charles S. Whitman. Although it was generally believed that he did not have a chance, he won by the narrow margin of 14,000 votes. He served four terms as governor, the first man in the history of the state to have this honour.

"Al" Smith, as he was affectionately known, showed extraordinary ability as a vote-getter. In 1920, when he ran against Nathan L. Miller, he was defeated in the Republican presidential landslide, but polled 1,000,000 more votes in his state than did the Democratic presidential nominee. He then became head of the United States Trucking corporation, but in 1922 was drafted to run for governor again. This time he defeated Miller, seeking re-election, 1,397,633 to 1,011,725—at that time the largest majority ever given a gubernatorial candidate in New York. In 1924 he defeated Theodore Roosevelt, Jr., and in 1926 defeated Ogden L. Mills. As governor, Smith fought for adequate housing, improved factory laws, proper care of the insane, child welfare and state parks. He effected a reorganization of the state government on a consolidated, businesslike basis. He repeatedly demonstrated his gubernatorial leadership by forcing Republican legislatures to accept his recommendations.

Smith was the first Roman Catholic to receive serious consideration as a presidential candidate in the United States. His religion combined with his long record as an opponent of prohibition, resulted in a prolonged deadlock at the Democratic national convention of 1924. His nomination was opposed by the Protestant "dry" faction led by William G. McAdoo. On the 103rd ballot a compromise candidate, John W. Davis, was nominated, but lost the election to Pres. Calvin Coolidge.

In 1928 Smith was the leading candidate for the Democratic presidential nomination. At the Houston (Tex.) convention of the party on June 28 he was again placed in nomination by Franklin D. Roosevelt. The first ballot gave him the necessary two-thirds vote of the delegates, and Sen. Joseph T. Robinson was later nominated for vice-president. Though the western and southern Democratic delegates managed to bury the hatchet at the convention they could not persuade the voters to do so in the election. The opposition to Smith in the rural districts of closely contested states in the west and south contributed to his defeat in the election.

Smith carried on an aggressive campaign, making several extended speaking tours into the south and west. Hailed by Roosevelt as the "happy warrior," he was a picturesque figure who made his brown derby, cigar and colourful speech his trademarks and "The Sidewalks of New York" his theme song. But when the electoral votes were counted it was found that he had lost to Herbert Hoover, 444 to 87. Smith lost his own state as well as five southern states that had not gone Republican since the reconstruction era. The popular vote was much closer, 21,391,000 to 15,016,000. Smith polled the largest popular vote ever given to a Democrat up to that time.

The remaining years of Smith's life were embittered by the financial difficulties of the Empire State building, of which he became president, and by a bitter conflict with Franklin D. Roosevelt. Smith lost contact with his old following and supported the

Republican presidential candidates in 1936 and 1940. He died on Oct. 4, 1944.

SMITH, CHARLOTTE (1749–1806), English novelist and poet, once famous for her sonnets and her romances, was born in London, May 4, 1749, the daughter of Nicholas Turner, a man of property. Her husband, Benjamin Smith, whom she married in 1765, was imprisoned for debt from December 1783 to July 1784 and then fled to France to avoid creditors. There his wife joined him until, by her efforts, he could return to England (1785). Two years later she left him and turned to writing to support her children (she had 12, of whom 6 survived her). She had already published *Elegiac Sonnets* (1784) but, although these were well received, her free translations of *Manon Lescaut* (1785) and part of *Les Causes Célèbres* (*The Romance of Real Life*, 1786) promised higher financial reward for novels: hence *Emmeline, or the Orphan of the Castle* (1788), *Ethelinde, or the Recluse of the Lake* (1789), which Fanny Burney enjoyed, etc. *Desmond* (1792), based on the innocent love of a man for a married woman, was accused of immorality, and its political ideas, inspired by the French Revolution, also caused some talk. Mrs. Smith began *The Old Manor House* (1793), generally considered her best novel, when, with Cowper and Romney, she was the guest of William Hayley (*q.v.*); she read a chapter to the company each evening. Scott praised "her invention . . . . her knowledge of the human bosom, her power of natural description, her wit and her satire"; but in spite of her Cowperlike attitude to nature and her radical ideas her novels, with their rather stilted dialogue and occasional Gothic effects, belong essentially to the large derivative group of 18th-century women novelists.

Toward the end of her life she turned to palatably instructive books for children, the best being *Conversations Introducing Poetry* (1804). She died at Tilford, near Farnham, Surrey, on Oct. 28, 1806.

See F. M. A. Hilbish, *Charlotte Smith* (1941).

SMITH, GEORGE (1840–1876), English Assyriologist who deciphered (1872) a cuneiform tablet in the British Museum that bore a Chaldean account of the flood (*see* Flood [in Religion and Myth]). He was born in Chelsea, London, on March 26, 1840, and apprenticed to an engraver of bank notes at 14. Through Sir Henry Creswicke Rawlinson, Smith was permitted to study inscriptions in the British Museum and in 1867 became an assistant in the department of Assyriology. His translation of one inscription established the date of a total eclipse of the sun in the month Sivan, in May 763 B.C., and another fixed the date of an invasion of Babylonia by the Elamites in 2280 B.C. In 1873 the *Daily Telegraph* gave 1,000 guineas to Smith for excavations in Mesopotamia that unearthed tablets at Nineveh (*q.v.*) with missing portions of the account of the flood. The British Museum sent Smith in 1874 and 1876 to continue excavations of the library of Ashurbanipal (*q.v.*); he died at Aleppo, Syr., on Aug. 19, 1876. (J. M. Wi.)

SMITH, SIR GEORGE ADAM (1856–1942), Scottish preacher and Semitic scholar who helped to make generally acceptable the higher criticism of the Old Testament, was born in Calcutta, India, on Oct. 19, 1856. Educated in Edinburgh (at the Royal High School, the university and New College), with vacation study at Tübingen and Leipzig, he taught at the Free Church College, Aberdeen (1880–82), during the suspension of W. Robertson Smith (*q.v.*). After ordination he made his reputation as a preacher at Queen's Cross Free Church, Aberdeen (1882–92), uniting sound scholarship with a vivid sense of the relevance of God's Word to the listening congregation. These qualities were apparent also in *The Book of Isaiah* (2 vol. 1888–90; revised 1929). During his tenure of the Old Testament professorship at the Free Church College, Glasgow (1892–1909), he made several lecture tours in the U.S. and published *The Historical Geography of the Holy Land* (1894; revised 1931), the outcome of detailed observation and investigation made in Palestine; it proved invaluable to Gen. Sir William Allenby in the Palestine campaign of 1917. At Glasgow Smith also produced *The Book of the Twelve Prophets* (two volumes, 1896–98; revised 1928), a life of his friend Henry Drummond (1898), *Modern Criticism and the Preaching of the Old Testament* (1901), and *Jerusalem* (two volumes 1907–08). The advanced views of *Modern Criticism* (lectures delivered at Yale) nearly led to a process for heresy against him at home. As principal of the University of Aberdeen (1909–35) he wrote *The Early Poetry of Israel* (1913) and *Jeremiah* (1923), was knighted in 1916, and was moderator of the General Assembly of the United Free Church of Scotland, 1916–17. He died at Balerno, near Edinburgh, on March 3, 1942.

See S. A. Cook in *Proceedings of the British Academy*, vol. 28 (1942), and the life by his widow, L. A. Smith (1943).

SMITH, SIR HARRY GEORGE WAKELYN, Bart. (1787–1860), British general, governor of Cape Colony and high commissioner in South Africa from 1847 to 1852, was born at Whittlesey, Cambridgeshire, on June 28, 1787, the son of John Smith, a surgeon. Commissioned as an ensign in the army in 1805, he saw service in South America (1807) and then for two periods during the Peninsular War. He took part in the retreat to, and battle of, Corunna in January 1809, and was at the storming of Badajoz (April 1812). Here two strikingly beautiful Spanish sisters, one of them, the 14-year-old Juana María de los Dolores de León, sought protection in the British lines. Smith later married Juana, who accompanied him constantly on his military and subsequent civil duties. From 1814 to 1815 Smith, now a captain, served as assistant adjutant general to the British force in the war between Britain and the United States, and was present at the capture and burning of Washington (August 1814). On his return to England he was appointed assistant quartermaster general to a division of the duke of Wellington's army in the Low Countries, in which capacity he served in the Waterloo Campaign of June 1815.

After a number of military postings in Britain, Smith went to Jamaica in 1826 as deputy quartermaster general of the forces there and in 1828 was transferred to the Cape Colony in the same capacity. On the outbreak of the sixth Kaffir War (*see* Kaffir Wars) in December 1834, Sir Benjamin D'Urban, governor of the Cape, appointed Smith, with the rank of colonel, commandant of the regular and the burgher forces, and second in command of the colony. Smith at once made his famous ride from Cape Town to Grahamstown (January 1835), covering the 600 mi. in 6 days, in order to allay panic in the eastern districts of the colony which were exposed to the depredations of the Amaxosa, a branch of the Bantu people. His soldierly qualities and vigorous conduct of the campaign earned him the admiration of the Boer farmers. At the end of the war Smith administered the frontier territory between the Keiskamma and Great Kei rivers (which was named the province of Queen Adelaide) by means of a benevolent despotism until the territory was returned to the tribes at the end of 1836.

After a brief period in Cape Town, Smith was appointed adjutant general of the army in India in March 1840. With the honorary rank of major general he distinguished himself in a number of engagements in 1845 and 1846, winning special fame as the hero of the victory over the Sikhs at Aliwal (Jan. 28, 1846), when he led the final charge which routed the enemy. For this achievement he was created a baronet and in November was promoted to be major general. He returned to the Cape in December 1847 as governor and also held the recently created office of high commissioner in South Africa. Soon after his arrival he ended the seventh Kaffir War and reannexed the old province of Queen Adelaide to the crown as British Kaffraria, where he instituted, as part of a civilizing policy, a number of far-reaching changes which reduced the authority of the chiefs.

In February 1848 he visited Natal, where he tried, with little success, to check a new emigration of Boers from that district. In the same month, he annexed to the crown, as the Orange River sovereignty, the territory north of the Cape Colony between the Orange and the Vaal rivers. Smith was faced with hostile demonstrations of the colonists in the Cape in 1848 and 1849 against the attempt of the colonial secretary, Earl Grey, to land convicts at the Cape. He faithfully transmitted their objections to London,

and in September 1849 refused to allow any of the convicts to come ashore. The precipitate nature of Smith's changes in British Kaffraria was probably the principal cause of the eighth Kaffir War (1850–53). The British government's dissatisfaction with his handling of the war, which was long and costly, caused his recall in March 1852. He subsequently held various military posts in Britain and was appointed lieutenant general in 1854. He died in London on Oct. 12, 1860. Harrismith (Orange Free State), Ladysmith (Natal), and Ladismith (Cape) are South African towns named after Smith and his wife. His autobiography, edited by G. C. Moore Smith, was published in two volumes in 1901. (L. M. Y.)

SMITH, HENRY JOHN STEPHEN (1826–1883), British mathematician who specialized in the theory of numbers, was born in Dublin, Ire., on Nov. 2, 1826. When he was two years old his father died and his mother left Ireland for England. After being privately educated he entered Rugby in 1841 and Balliol College, Oxford, in 1844. He was elected a fellow of Balliol in 1850 and Savilian professor of geometry in 1861. He was elected a fellow of the Royal Society in 1861, served on various royal commissions, and from 1877 was chairman of the managing body of the Meteorological Office. He died at Oxford on Feb. 9, 1883.

Smith published a few papers on geometry and then began a study of the existing work on the theory of numbers. The results of his researches are contained in his *Report on the Theory of Numbers*, which appeared in the British association volumes from 1859 to 1865. His further original researches on the subject were communicated to the Royal Society in two memoirs, "Systems of Linear Indeterminate Equations and Congruences" and the "Orders and Genera of Ternary Quadratic Forms" (*Phil. Trans.*, 1861 and 1867). After 1864 he devoted himself chiefly to elliptic functions. His *Collected Papers*, prefaced by several biographical notices, were edited by J. W. L. Glaisher (1894). (O. Oe.)

SMITH, JEDEDIAH STRONG (1799–1831), an explorer of the American West who deserves to rank with Lewis and Clark (*see* Lewis and Clark Expedition); he was the most notable single personality of the fur trade era. Born Jan. 6, 1799, in Jericho (now Bainbridge), N.Y., he first ascended the Missouri River with the first fur trade venture of William H. Ashley and Andrew Henry in the spring of 1822. Smith quickly rose to prominence, for he was intelligent, tough, and adaptable, though "a mild man and a Christian." In the fall of 1823 he led a party of fur hunters to Wind River, and in March 1824, made the effective discovery of South Pass (in present-day Wyoming), gateway to the American West. (The pass had been traversed a dozen years earlier by Robert Stuart, but the discovery was not followed up.) After a year as Ashley's partner, in 1826 Smith formed a new partnership with David E. Jackson and William L. Sublette and promptly led to southern California the first expedition to reach that area from the Great Salt Lake country. The following spring Smith became the first man to cross the Sierra Nevada and traverse the Great Basin from west to east. On a second expedition in 1827–28 he made the first exploration by land up the California-Oregon coast. All these explorations were financed by beaver catches. In 1830 Smith, Jackson and Sublette sold out to the new Rocky Mountain Fur Company, transporting their furs to St. Louis, Mo., in the first wagons ever brought to the northern Rockies.

On May 27, 1831, Smith was killed by Comanches on the Cimarron River, while en route to Santa Fe, N.M. This early death delayed the publication of his journals and maps, which would have signally advanced geographic knowledge.

Bibliography.—Jedediah Smith, *Travels*, ed. by Maurice S. Sullivan (1934); Dale L. Morgan, *Jedediah Smith and the Opening of the West* (1953); Dale L. Morgan and Carl I. Wheat, *Jedediah Smith and His Maps of the American West* (1954). (D. L. M.)

SMITH, JOHN (*c.* 1580–1631), soldier, explorer, author, and one of the principal founders of the first permanent English colony in North America, was born into a farming family at Willoughby, Lincolnshire, Eng. At the age of 15 he left school and was apprenticed to a wealthy merchant. Soon after his father's death he went to fight in the Netherlands. At the age of 20, having returned to England and studied military horsemanship, he went off to the wars against the Turks in Hungary. His exploits there once questioned, have been substantiated by Hungarian records. His acts included deluding the enemy by the use of fireworks, for which he was made a captain, and killing three opponents in individual combat. Left for dead on the battlefield, Smith was taken as a captive into Asiatic Turkey from which he escaped into Russia and eventually returned to England in 1604.

ENGRAVING IN THE CORNER OF A MAP OF NEW ENGLAND BY S. DE PASSE, 1616; BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

JOHN SMITH

He soon attached himself to a group that was preparing to establish an English colony in North America. In 1606 the way was cleared with the granting of a royal charter to the Virginia Company. When the colonists (105 in number according to Smith) set sail on Dec. 20, Smith was one of their acknowledged leaders.

On April 26, 1607, the three little ships ("Susan Constant," "Godspeed," and "Discovery") sailed into Chesapeake Bay. According to instructions given in London, the colonists then opened a sealed box that contained the names of seven men who were to form the governing council of the colony. Smith, though named, was not allowed to take his seat because he had been charged with concealing a mutiny. A few weeks later, having proved his courage and resourcefulness as explorer and soldier, he was admitted to the council. Meanwhile, on May 14, the colonists settled at Jamestown, Va. Soon after the "Susan Constant" returned to England for badly needed supplies, the colony suffered a virulent disease that nearly killed Smith. Food was running short; no adequate houses had been built; and discord was rising among the settlers. The council, reduced to four members, deposed their president, Edward Maria Wingfield. Smith, taking charge of outdoor affairs, soon became the dominant figure. He directed the building of houses, traded with the Indians, and began the series of river voyages that enabled him to draw a remarkably fine map of Virginia. While exploring the Chickahominy River in December 1607, he was ambushed and captured by Indians. Taken to the great chief Powhatan, he was about to be executed when, according to Smith's account, the chief's daughter Pocahontas, a girl of about 13, threw herself between him and his executioners. Thereafter Smith was initiated into the tribe and Pocahontas became his friend, coming often to Jamestown with gifts and on one occasion warning Smith of a planned attack.

When Smith returned to Jamestown, Gabriel Archer, a member of the council, tried to have him hanged for the loss of the men who had gone with him, and would have succeeded but for the return of Captain Christopher Newport from England with fresh supplies. He found only 38 of the original settlers still alive.

Smith, after further exploration of Chesapeake Bay and its rivers, became president of the colony on Sept. 10, 1608. He expanded the fort to form a five-sided enclosure, tightened up on military training and guarding, sent off boats to trade for food, went with Newport to crown Powhatan according to orders received from London, and continued to get corn from the Indians where others often failed. But the situation remained desperate. After two years the English still depended on England and the Indians for their food. They had failed to find any gold or silver or to return any profits to the investors in London. They had not found the hoped-for passage to the Pacific and were in constant danger from the Indians. Under Smith's direction, however, small quantities of tar, pitch, and soap ashes were made, a well was dug, 20 houses were built, fishing was put on a regular basis, crops were planted, and outlying forts were built.

In August 1609, four supply ships arrived, bringing several settlers who had formerly been sent home and were bitter enemies of Smith. Gabriel Archer and John Ratcliffe demanded that Smith give up the government because, under a new charter granted by King James, a new lieutenant governor, Sir Thomas Gates, and an admiral, Sir George Somers, were on their way with five more ships, with Lord De La Warr to follow as governor. Since the new officers and their commissions had not arrived, however, Smith insisted he must govern until they came, and refused to admit Archer and Ratcliffe to their former council seats, though he accepted John Martin, another former member. Hoping to improve a bad situation by dispersion, Smith sent Francis West (De La Warr's brother) up to the falls of the river (the site of Richmond) with 120 men. Martin went down the river with an equal number to settle near the Nansemond Indians. In September, returning from an attempt to straighten out difficulties among West's men, Smith was so seriously injured when his powder bag caught fire in his boat that he was impelled to go aboard a ship that was soon to leave for England. The measure of Smith's ability is found in what happened after he left. Ratcliffe and a whole company were slaughtered by Indians; West sailed off with another group to England; all the domestic animals were killed and eaten; guns were traded to the Indians for food; and still the colony starved. Men fed upon roots and acorns, and even upon their dead comrades. Of the 500 Smith left behind, only 60 were alive when the new leaders, shipwrecked in the Bermudas, finally reached Jamestown. Within a few days they decided to abandon the settlement and return to England, and were on their way when they met De La Warr coming with new supplies.

Accusations against Smith had been sent to the Virginia Company in London, but the disposition of his case is not known, as the records have disappeared. Time, however, vindicated many of his policies—the necessity of dealing firmly with the Indians, the wisdom of spreading out the plantations, the folly of trying to produce naval stores, silk, glass, or gold.

Having quarreled with the Virginia Company, but still eager to explore and settle in America, Smith made contact with the Plymouth Company, which had a charter for colonizing the northern coast from 38° to 45°. In 1614, having arranged for the financing of two vessels, he sailed to the area he named New England, carefully mapping the coast from Penobscot Bay to Cape Cod. Though he failed to find gold and whales, he did catch some fish and trade for furs. He saw that to make fishing profitable, settlers should be established on land to dry and pack the catch. In time each port of old England could have its counterpart in New England.

In 1615 Smith set out again, this time to establish a permanent settlement in New England. A ship of 200 tons and a smaller one of 50 sailed from Plymouth, but within 200 miles they were separated by a gale. The larger lost its masts and had to return to port. In a 60-ton bark Smith set out again, but was soon captured by French pirates. Smith's ship was eventually freed, but he himself (through the treachery of his own captain) was left aboard one of the pirate ships. When they attacked Spanish ships, Smith joined in the fighting on promise of a share in the spoils. During his three months with the pirates he wrote his *Description of New England*, a counterpart to his *Description of Virginia* published in 1612. In the end the pirates threatened to accuse him as the destroyer of French settlements in America unless he renounced his share. So he escaped from the vessel at night, survived a storm in a rowboat, and reached shore only to learn that the pirates had sunk in the storm with all their spoils.

Returning penniless to England, Smith met his friend Pocahontas, now on a visit with her husband John Rolfe, and in 1617 assembled three ships for another colonizing attempt, but was windbound for three months and never got off. He lived, wrote, and talked New England for the rest of his life, attempting to go first with the Pilgrims and then with the settlers of Boston, both of whom benefited from his books and maps. But he never saw America again. Much of his time was now devoted to writing. His works include the beautifully printed *Generall Historie of Virginia, New England and the Summer Isles* (1624), *The Seaman's Grammar* (1627), and *The True Travels, Adventures, and Observations of Captaine John Smith in Europe, Asia, Africa and America* (1630), which tells of his early exploits. A set of first editions of his works, if they could be assembled, would cost over $25,000.

As a pioneer in Virginia, explorer of the Chesapeake and other rivers, map maker, namer of New England (to which his press agentry attracted the Puritan settlements), Smith might well say that the English colonies were "pigs of his sow." He had a faith in America and an understanding of its greatness as a cradle of freedom which few men of his time approached. He died in June, 1631, and was buried in St. Sepulchre's Church, London, where his epitaph may still be seen.

Smith's works were edited by Edward Arber (Birmingham, 1884, and Edinburgh, 1910). They have often been printed in part in collections of voyages. *Captain John Smith, His Life & Legend* (1953), by Bradford Smith, is based on evidence collected from contemporary sources gathered for the first time, most of which corroborate Smith's own accounts. (B. Sm.)

SMITH, JOSEPH (1805–1844), U.S. founder of the Mormon religion, was born at Sharon, Vt., Dec. 23, 1805, the third son of Joseph and Lucy Mack Smith. His early career is shrouded in controversy. Neighbours in Palmyra, N.Y., described him as a romancer and diviner who dug for buried treasure, and their stories can be largely verified by court records, early newspaper accounts, and the autobiography of his mother. In his own history, written after 1838, Smith described himself as an unschooled, pious boy who had a vision of God and Jesus Christ at the age of 14. At 17, he said, an angel directed him to buried golden plates containing a history of the American Indians, which described them as descendants of Hebrews who had centuries earlier sailed to America by way of the Pacific. This *Book of Mormon* he translated from "reformed Egyptian" with the aid of magic stones he called the Urim and Thummim.

By most objective scholars the book is regarded as a potpourri of local Indian origin legends, fragments of autobiography, and the current religious and political controversies, particularly Anti-masonry, all transformed with remarkable ingenuity into a religious saga of quasi-biblical authority. After its publication in 1830, Smith offered it as scientific evidence of his divine calling, and claimed that his new church, organized April 6, 1830, was a restoration of the ancient, primitive Christian religion.

Converts in ever-increasing numbers followed Smith from New York to Ohio, then to Missouri, and on to Illinois, despite great suffering. The young prophet governed his people with the help of revelations, which dealt with such divergent matters as the anthropomorphic nature of God, the communistic United Order, and the size, location, and financing of a hotel. He taught that the heavens are peopled with many gods, and that every man can aspire in time to be a god himself.

Joseph Smith was a man of commanding presence, athletic grace, and prodigious personal charm. A genius at improvisation, he managed to combine Jewish and Christian mysticism with the goal of perpetual prosperity, and to establish the tradition of Mormonism as a complete "way of life." Although his revelation on polygamy was not made public (by Brigham Young) until 1852, eight years after Smith's death, and though it is not supported by *The Book of Mormon*, there is evidence that he may have married as many as 50 wives. He publicly acknowledged only his first, Emma Hale Smith, who bore him nine children.

When a handful of dissenting Mormons attacked him in their newspaper, Smith had their press destroyed. For this he was imprisoned, with his brother Hyrum. On June 27, 1844, an anti-Mormon mob stormed the jail at Carthage, Ill., and shot both men. The church split into pieces, but the majority followed Brigham Young (*q.v.*), a sagacious administrator and colonizer, who led the Mormon exodus to Great Salt Lake. A smaller group, led by the eldest of Smith's four surviving sons, who denied that their father had practised polygamy, settled in Independence, Mo. (*See* also LATTER-DAY SAINTS, CHURCH OF JESUS CHRIST OF.)

Joseph Smith's writings include, in addition to *The Book of Mormon* (1830), *A Book of Commandments for the Government*

of the Church of Christ (1833); *Doctrine and Covenants of the Church of The Latter Day Saints* (1835).

Brodie, *No Man Knows My History: the Life of Joseph Smith, the Mormon Prophet* (1945); Thomas O'Dea, *The Mormons* (1957); Lucy Mack Smith, *Biographical Sketches of Joseph Smith the Prophet and His Progenitors for Many Generations* (1853); B. H. Roberts (ed.), *History of the Church of Jesus Christ of Latter-Day Saints*, 6 vol. (1902–12). (F. M. B.)

SMITH, SIR KEITH MACPHERSON (1890–) and **SIR ROSS MACPHERSON** (1892–1922), brothers, Australian pioneer aviators, were born at Adelaide, S. Austr., on Dec. 20, 1890, and Dec. 4, 1892, respectively. They were both educated at Queen's school, Adelaide, and at Warriston school, Moffat, Scotland. During World War I, Keith served in the Royal Flying Corps and Royal Air Force as a pilot, 1917–19, while Ross served with the Australian Light Horse in Gallipoli and Sinai. In 1916 he learned to fly in Egypt and spent the last two years of the war in the Australian flying corps in Palestine. He made the first flight from Cairo to Calcutta in 1918. In Nov.–Dec. 1919, Ross as first and Keith as second pilot, in a Vickers Vimy twin-engined biplane with Rolls Royce 375 h.p. engines, accompanied by Sgts. J. M. Bennett and W. H. Shiers as mechanics, made the first flight from England to Australia, landing at Darwin, Northern territory, on Dec 10, 1919. For this flight the brothers received knighthoods and the prize of £10,000. Three years later they began preparations for a pioneer round-the-world flight in a Vickers pusher-amphibian aircraft, but Ross was killed, together with Bennett, while testing the aircraft at Brooklands, Eng., on April 13, 1922. Keith went into business in Sydney, Austr. (D. CR.)

SMITH, SEBA (MAJOR JACK DOWNING) (1792–1868), U.S. editor and humorist, creator of Major Jack Downing, a rustic Yankee whose horse sense and wise saws as the purported counselor and friend of Andrew Jackson brought laughs that swept the country, was born in Buckfield, Me., on Sept. 14, 1792. A graduate of Bowdoin college, Brunswick, Me., Smith in 1829 founded the *Portland Courier*, where the Major's fictional letters first appeared in Jan. 1830, continuing later in the *National Intelligencer* until July 1853. Major Jack was a common man magnified as oracle; yet there was irony in his role of threadbare office seeker exposing follies in a mobocracy. As adviser to President Jackson, Jack was in the heyday of his popularity; this led to shameless counterfeiting of Smith's invention and to his collection of the letters in book form, the last volume being published in 1859 under the title of *My Thirty Years Out of the Senate*. In the Downing letters Smith is intent on the portrayal of New England character, an aim more completely carried out in his *Way Down East* (1854). Smith's title to distinction comes from his hitting upon something new in humour that has become a part of American tradition. Practically forgotten himself, he numbers among his followers in satire James Russell Lowell's Hosea Biglow, Artemus Ward and Will Rogers.

Smith died July 28, 1868, in Patchogue, N.Y.

SMITH, SYDNEY (1771–1845), English man of letters and canon of St. Paul's (1831–45), was not only one of the foremost preachers of his day but, as Macaulay said, was, in controversy, "the greatest master of ridicule since Swift," and for wit in conversation "beat all the men I ever met" (Thomas Moore). The intellectual versatility and warmth of feeling beneath his superficial frivolity are best seen in his letters.

The second son of a wealthy and eccentric landowner, Sydney Smith was born at Woodford, Essex, on June 3, 1771. At Winchester, where he went in 1782, he acquired a lifelong hatred of public schools. In 1789 he went up to New College, Oxford, with a scholarship, exchanging it in 1791 for a fellowship of £100 a year. His father refused to let him study law, and, after taking his degree in 1792, he was ordained in 1794 and went as curate to Netheravon, near Amesbury, on Salisbury Plain. In 1797 the squire of Netheravon asked him to accompany his son to Germany as tutor; war intervened, and they went to Edinburgh, where Smith attended lectures in moral philosophy (under Dugald Stewart), chemistry, and medicine. He made many friends, among them Henry Brougham and Francis Jeffery (*qq.v.*), with whom, in 1802, he founded the *Edinburgh Review*. The suggestion was Smith's, and, although never officially editor, he acted as one for the first three numbers. He continued to write for it for 25 years, and his trenchant articles were a main element in its success. In 1800 he married and published his first book. In 1803 he moved to London.

There he quickly made friends, and was appointed alternate Sunday evening preacher at the Foundling Hospital, and morning preacher at Berkeley and Fitzroy Chapels, Mayfair. In 1804 he gave a course of lectures on moral philosophy at the Royal Institution. Their blend of sense and wit attracted attention and people flocked to hear him: the second and third series (1805 and 1806) were also successful.

Had he been on the powerful side in politics, or willing to modify his opinions, Smith would soon have been a bishop. As it was, all that his friends Lord and Lady Holland could achieve, when the predominantly Whig "ministry of all the talents" took office in 1806, was presentation to the living of Foston-le-Clay, Yorkshire. At first he discharged his duties through a curate, but enforcement of the Clergy Residence Act put an end to his pleasant metropolitan life, and in June 1809 he left London.

Meanwhile, in March 1807 the "ministry of all the talents" had been forced to resign on the issue of Catholic emancipation. Smith supported emancipation on liberal and rational grounds. In the summer of 1807 he published the first of his famous *Letters of Peter Plymley to my Brother Abraham who lives in the Country*, attacking Protestant ignorance, obscurantism, and bigotry. Its success was immediate, and it was followed by four more in 1807, and five in 1808, in which year they were collected. Inspired by "a passionate love for common justice, and for common sense," and armed with the weapon of ridicule, Smith did more than anyone else to change public opinion. The letters were published anonymously and were never openly acknowledged, but rumours of Peter Plymley's identity soon got abroad, and Lord Holland wrote to Smith, expressing his view, and Lord Grenville's, that there had been "nothing like it since Swift," but pointing out that, for this, his wittiest performance, Smith had lost a bishopric.

In Yorkshire, although he hated the country, Smith soon showed his characteristic energy and cheerfulness. He planned and built his own house, learned to manage a farm, bred horses, set up a dispensary, and won his parishioners' affection. He continued to support Catholic emancipation, in 1826 publishing *A Letter to the Electors, upon the Catholic Question*, one of his most effective polemics. At last, in 1828, he gained preferment. Just before going out of office, the chancellor, Lord Lyndhurst, presented him with a prebendal stall at Bristol Cathedral, and in 1829, having exchanged his living at Foston for one at Combe Florey, he moved to Somerset.

When he became a canon, Smith stopped writing for the *Edinburgh Review*, thinking it more fitting that a dignitary of the church should sign what he wrote. It was expected that, when the Whigs came to power, he would be made a bishop, but opposition was strong. He only succeeded (September 1831) in exchanging his Bristol stall for a residentiary canonry at St. Paul's Cathedral, which necessitated his living in London three months of the year. He attributed his failure to be made a bishop to his being a "high-spirited, honest, uncompromising man, whom all the bench of bishops could not turn upon vital questions."

He was a champion of parliamentary reform and one of his best fighting speeches was at Taunton (Oct. 11, 1831) when he made the well-known comparison of the House of Lords, which had just thrown out the Reform Bill, with Dame Partington, with mop and pattens, "vigorously pushing away the Atlantic Ocean."

Despite disappointment, and lasting grief at the death in 1829 of his eldest son, Smith retained his high spirits, wit, practical energy, and powers of argumentative ridicule to the last. His *Letter to Archdeacon Singleton, on the Ecclesiastical Commission* (1837), and the other *Singleton Letters* (1838–39); and his *Petition* and *Letters* (1843, to the *Morning Chronicle*; reprinted 1844) on Pennsylvania's repudiation of its debts are as vigorous and spirited as the best of his early essays for the *Edinburgh Review*.

On his brother Courtenay's death in 1839, Smith inherited £50,000, and bought a house in London; and there, on Feb. 22, 1845, he died.

SMITH, THEOBALD (1859–1934), U.S. pathologist, a pioneer in the comparative etiology and immunology of infectious and parasitic diseases, was born in Albany, N.Y., July 31, 1859. He earned baccalaureate and medical degrees at Cornell University, Ithaca, N.Y. (1881), and Albany Medical College (1883). From 1884 to 1895 Smith was director of the pathological laboratory of the Bureau of Animal Industry in Washington, D.C., where he was also professor of bacteriology at Columbian University (later George Washington University). He served also as director of the pathological laboratory of the Massachusetts State Board of Health (1895–1915); as professor of comparative pathology at Harvard University (1896–1915); and as director of the department of animal pathology of the Rockefeller Institute for Medical Research (1915–29). Some of his most valuable research included the role of ticks in transmitting Texas or southern cattle fever (1888); his differentiation of bovine from human tubercle bacilli (1898), which was of value to Robert Koch in his later work; and the demonstration that killed cultures of bacteria may produce immunity. He died on Dec. 10, 1934.

See Hans Zinsser, "Biographical Memoir of T. Smith," *Biographical Memoirs of National Academy of Science* (1937–38), with bibliography. (W. F. N.)

SMITH, WALTER BEDELL (1895–1961), U.S. Army officer and diplomat, was born in Indianapolis, Ind., Oct. 5, 1895. He began his military career as an enlisted man in the Indiana National Guard, 1910–15, and in 1917 was commissioned second lieutenant of infantry in the U.S. Army. In February 1942, during World War II, Smith was appointed secretary of the joint chiefs of staff and U.S. secretary of the combined chiefs of staff, with the rank of brigadier general. The following September he became chief of staff, European theatre of operations, and chief of staff to Gen. Dwight D. Eisenhower, serving in those posts until Eisenhower's departure from Europe after the war. Smith negotiated and accepted for the Allies the surrender of Italy in 1943 and that of Germany in 1945.

On his return to the United States in 1945 Smith became chief of the Operations and Planning Division of the War Department general staff. Shortly thereafter he was appointed U.S. ambassador to the Soviet Union, holding the post from 1946 to 1949. Later he commanded the U.S. 1st Army, 1949–50, was director of the Central Intelligence Agency, 1950–53 (having been promoted full general in 1951), and on Jan. 31, 1953, retired from active military service to become undersecretary of state. In October 1954 he resigned from government service and entered private business. He died in Washington, D.C., on Aug. 9, 1961. General Smith was the author of *My Three Years in Moscow* (1950) and *Eisenhower's Six Great Decisions* (1956). (F. C. PE.)

SMITH, WILLIAM (1769–1839), English geologist, called the father of English geology and known as "Strata Smith," was born at Churchill in Oxfordshire on March 23, 1769. At 18 he became assistant to a surveyor, Edward Webb, of Stow-on-the-Wold, and traversed the oölitic lands of Oxfordshire and Gloucestershire, the Lias (Lower Jurassic) clays and red marls of Warwickshire and other districts, studying their varieties of strata and soils. In 1791 his observations at Stowey and High Littleton in Somersetshire first impressed him with the regularity of the strata. In 1793 he executed the surveys and levelings for the line of the Somerset coal canal, in the course of which he confirmed his earlier supposition, that the strata above the coal were not horizontal, but inclined in one direction—to the east—so as to terminate successively at the surface.

On being appointed engineer to the canal in 1794 he made a tour with regard to inland navigation. He carefully examined the geological structure of England, and corroborated his generalization of a settled order of succession in the strata. In 1794 he made his first geological map—that of the vicinity of Bath—showing the ranges of the different strata in the area.

In 1799 Smith dictated his first table of British Strata (presented to the Geological society of London in 1831). It was headed *Order of the Strata, and Their Imbedded Organic Remains, in the Neighbourhood of Bath; Examined and Proved Prior to 1799.* In 1813 Joseph Townsend, a clergyman who was also a geologist, published, with acknowledgment, much information on the English strata communicated by William Smith, in a work entitled *The Character of Moses Established for Veracity as an Historian, Recording Events From the Creation to the Deluge.* Meanwhile Smith was completing and arranging the data for his large *Geological Map of England and Wales, With Part of Scotland* (15 sheets, 1815). The map—of great significance in the development of modern geology—was reduced to smaller form in 1819, and from this date to 1822, 21 separate county geological maps and several sheets of sections were published in successive years, constituting a *Geological Atlas of England and Wales.*

Smith's collection of fossils was purchased in 1816–18 by the British museum. In 1817 a portion of the descriptive catalogue, *Stratigraphical System of Organised Fossils,* was published. In 1816 he had commenced the publication of *Strata Identified by Organised Fossils,* with figures printed on paper to correspond in some degree with the natural hue of the strata. In this work (of which only four parts were published, 1816–19) is exemplified the principle he established of the identification of strata by their included organic remains, which changed the whole conception of paleontology. In 1831 the Geological society of London conferred on Smith the first Wollaston medal; and from the government he received a life pension of £100 per annum. The last years of his life were spent at Hackness (of which he made a good geological map), near Scarborough; and in the latter town. He died at Northampton on Aug. 28, 1839.

Smith's *Memoirs,* edited by his nephew, John Phillips, appeared in 1844.

See C. L. and M. A. Fenton, *Giants of Geology,* rev. ed., pp. 70–83 (1952).

SMITH, WILLIAM ROBERTSON (1846–1894), Scottish Semitic scholar and encyclopaedist, whose introduction in the pages of *Encyclopædia Britannica* of the new higher criticism of the Old Testament from Germany led to his being accused of heresy, and who later did fruitful research into comparative religion and social anthropology. He was born on Nov. 8, 1846, at Keig in Aberdeenshire. Educated at home by his father, he had a brilliant career at Aberdeen University (1861–66) and studied for the ministry at New College, Edinburgh (1866–70), for half the time being concurrently assistant to P. G. Tait, professor of natural philosophy at Edinburgh University. In 1867 he spent the summer studying at Bonn and in 1869 at Göttingen. He was ordained in 1870 on his appointment as professor of Oriental languages and Old Testament exegesis at the Free Church College of Aberdeen. Two years later he again visited Göttingen, studying Arabic. Few others in Britain were at that time familiar with the higher critical work of Old Testament scholars on the continent of Europe, and when Robertson Smith's articles on biblical subjects, notably that on the Bible itself (1875), appeared in the ninth edition of *Encyclopædia Britannica* the authorities of the Free Church took strong exception to them.

In 1877 a church committee reported that Smith's advanced views were incompatible with his being a teacher of candidates for the ministry. The assembly in June 1877 suspended him from his teaching duties. He demanded a formal trial and conducted his defense in the protracted case (1878–80) with conspicuous ability and courage, showing that his views did not conflict with the formulation of his church's belief in the inspiration of Scripture. Mean-

while he continued his scholarly work, including that of a reviser of the Authorized (King James) Version of the Old Testament, a task to which he had been appointed in 1875. He also perfected his Arabic by residence and travel in Egypt and other Middle Eastern countries during the winters of 1878 and 1879. In May 1880 the assembly dropped the indictment against him. A second attack on his opinions was launched after the publication in June of his article "Hebrew Language and Literature" in *Encyclopædia Britannica*. He was again suspended, and in May 1881 the assembly voted no confidence in him as a professor and he was removed from his chair (*see* further SCOTLAND, FREE CHURCH OF: *Theological Developments*).

The next month he was appointed joint editor of *Encyclopædia Britannica*. He moved to Edinburgh, and two crowded courses of lectures which he delivered there and in Glasgow respectively in 1881 and 1882 were published as *The Old Testament in the Jewish Church* (1881) and *The Prophets of Israel* (1882). In 1883 he was appointed Lord Almoner's Professor of Arabic at Cambridge and took up residence in Trinity College, moving to Christ's College in 1885 on his election as a professorial fellow there. His Oriental books are preserved at Christ's College. He remained editor in chief of *Encyclopædia Britannica* until the ninth edition was completed in 1888, though much of the work now devolved on a resident editor in Edinburgh, and continued to contribute many articles to it. His article "Sacrifice" (1886) together with his earlier book *Kinship and Marriage in Early Arabia* (1885) are important landmarks in the study of comparative religion, for which he had long had an interest through the influence of his close friend the ethnologist J. F. McLennan.

In 1886 Robertson Smith became university librarian at Cambridge, a post which he relinquished in 1889 on his appointment to succeed William Wright as Sir Thomas Adams's Professor of Arabic. In the same year appeared his most original work, *Lectures on the Religion of the Semites*, which had been delivered in Aberdeen. His health broke down in 1890 and remained precarious until his death at Cambridge on March 31, 1894. One of the most remarkable men of his time, a generous friend, and a brilliant conversationalist, he was regarded by continental scholars and by orientalists generally as the foremost Semitic scholar in Britain.

BIBLIOGRAPHY.—*Life*, with list of his publications, by J. S. Black and G. W. Chrystal (1912). *See* also T. K. Cheyne, *Founders of Old Testament Criticism* (1893); James Bryce, *Studies in Contemporary Biography* (1903); C. E. Raven and S. A. Cook, *William Robertson Smith* (1951). (D. W. TH.)

SMITH COLLEGE, an institution for the higher education of women at Northampton, Mass., was founded under the will of Sophia Smith (1796–1870) of Hatfield, who chose the neighbouring town of Northampton as the site of the college and selected the first trustees. The college was chartered in 1871 and opened in 1875. It became the largest independent college for women in the United States. *See* NORTHAMPTON (Mass.).

SMITHFIELD, an area in the north of the City of London, Eng., known chiefly for its meat market. The market, now administered by the Corporation of London, existed in A.D. 1183. The site also was used for jousting and military training, as a place of execution during the Reformation and Counter-Reformation and for the ancient Bartholomew Fair which is regarded as the forerunner of the famous Caledonian market developed at Islington after the live cattle trade was transferred there from Smithfield in 1855. The several sections of the market, which have been progressively established since 1860, handle fresh and frozen meat, poultry, provisions, fish, and fruit; and 15 mi. of meat rails can accommodate more than 9,000 tons daily with ample cold storage facilities. Supplies are received mainly from Great Britain, the Commonwealth, Europe, and South America. The church of St. Bartholomew the Great is a fragment of the church of the Augustinian priory of St. Bartholomew founded by Rahere in 1123. St. Bartholomew's hospital, founded in 1137, one of the great teaching hospitals of London, was rebuilt beginning in 1730. (H. G. B.)

SMITHSON, JAMES (1765–1829), English scientist and founder of the Smithsonian Institution at Washington, D.C., was the natural son of Hugh Smithson Percy, first duke of Northumberland of the third creation. The duke's family name was Smithson. James Smithson's mother, Elizabeth Keate Macie, was a gentlewoman of large fortune, who had been twice married before James Smithson was born. She was a lineal descendant of King Henry VII. Most of Smithson's large fortune came from his mother's family but some also came from his father's relatives. He was educated at Pembroke College, Oxford, and is said to have been the best chemist and mineralogist of his year. He later became well known for his important work in these fields. The carbonate of zinc is named smithsonite (*q.v.*) in his honour. At the age of 22 he was admitted into membership in the Royal Society on the recommendation of the great physicist Henry Cavendish, among others. He had a great regard for original research and publication. He wrote: "Every man is a valuable member of society who by his observations, researches, and experiments procures knowledge for men."

Smithson never married. Much of his life was spent on the continent, where he was well acquainted with the scientific leaders of the period. He died in Genoa, Italy, on June 27, 1829. The founding of the Smithsonian Institution was the result of a provision of Smithson's will. During his life Smithson never visited America, but in 1904 his remains were brought to the U.S. and are now interred in the original Smithsonian building. *See* also SMITHSONIAN INSTITUTION. (L. CAR.)

SMITHSONIAN INSTITUTION, an institution of learning in Washington, D.C., founded by the bequest of an English scientist, James Smithson (*q.v.*). His estate was left to a nephew, Henry James Hungerford, with the stipulation that, should Hungerford die without issue, or should his issue die intestate or under 21, the whole estate should go "to the United States of America, to found at Washington, under the name of the Smithsonian Institution, an establishment for the increase and diffusion of knowledge among men." Hungerford died without issue in 1835. There was much opposition in the U.S. to the acceptance of Smithson's bequest, especially by John C. Calhoun and others, who held that Congress had no power under the Constitution to accept such a gift, but it was accepted, largely through the efforts of John Quincy Adams.

Establishment.—In September 1838, £104,960 in gold sovereigns was delivered from the clipper "Mediator" to the Philadelphia mint, where it was recoined into U.S. money to the amount of \$508,318.46. In 1867, after the death of Hungerford's mother, a residuary legacy of \$26,210 was received and the fund then amounted to \$650,000. By savings of interest and by other gifts the fund was increased.

After ten years of debate, Congress in 1846 accepted the trust and created by enactment an "establishment" called the Smithsonian Institution, consisting of the president of the United States the vice-president, the chief justice, and the members of the president's cabinet. Smithson's money, a great fortune in that day, was lent to the U.S. Treasury, the government agreeing to pay perpetually 6% interest upon it. The act of Congress that created the institution provided that it should be governed by a board of regents composed of the vice-president and chief justice, three members of the Senate, three members of the House of Representatives, and six private citizens. The institution has a secretary who is its executive officer. The act also provided for a library and for a museum to contain "objects of art and of foreign and curious research, and objects of natural history, etc.," belonging to the United States. The museum was later designated the United States National Museum but remains under the direction of the Smithsonian Institution.

The regents met for the first time on Sept. 7, 1846, and in the autumn of the same year they elected as secretary Joseph Henry (*q.v.*), then a professor at Princeton University, known for his experiments on the electromagnet and other subjects relating to electricity. Under his guidance the institution took shape. Henry seized the unique opportunity offered by the opening up of the great western areas of the United States to make collections of vegetation and wildlife and to study the Indian tribes. A principal feature of his administration was the establishment of international exchanges of scientific literature.

The diffusion of knowledge was promoted by publishing a series of periodical reports on the progress of different branches of knowledge, occasional separate treatises on subjects of general interest, and monographs on special subjects investigated by experts. The Smithsonian was probably the first establishment in the United States to have a staff of full-time research scientists in a broad series of fields. In 1846 a plan was presented for the unification and systematization of weather observation under the institution. In December 1847 an appropriation was made by the board for such meteorological research; in 1849 telegraphic transmission of meteorological intelligence collected by the institution was begun; weather maps were successfully made in 1856. In 1870 the meteorological work of the institution was incorporated with the U.S. Army Signal Corps. Still later the U.S. Weather Bureau was established by act of Congress. After 1854 Henry's annual reports contained a general appendix with reports of lectures, such as were held under the auspices of the institution until 1865, summaries of correspondence, special papers, etc. On the grounds of the Smithsonian is a bronze statue of Joseph Henry by W. W. Story.

National Museum.—Spencer F. Baird (*q.v.*), Henry's successor, incorporated in the general appendix annual reports on the progress of the sciences. He also perfected Henry's system of international exchanges under which the institution, through agents in the principal cities of the world, exchanges its own publications, those of other departments of the U.S. government, and those of learned societies for foreign publications. Baird had been at the head of the U.S. National Museum before he became secretary of the institution, and the museum particularly was developed during his administration. It was built up around the collections of the U.S. Patent Office, which were turned over to it in 1858, and those of the National Institute, transferred to the Smithsonian in 1861 when the institute was dissolved. A part of the collection (including Smithson's collection) was destroyed by fire in 1865. The museum gained much valuable archaeological and ethnological material from the exploring parties sent out under John Wesley Powell (*q.v.*). It obtained excellent ichthyological specimens through Baird's position as U.S. fish commissioner, and acquired general collections from the Centennial Exhibition of 1876. Its great collection of plants is known as the National Herbarium. The museum had a phenomenal growth.

The museum comprises two units: the Museum of Natural History and the Museum of History and Technology. In the 1960s it occupied parts of four buildings and its catalogued objects totaled approximately 60,000,000, distributed among its various departments (anthropology, botany, zoology, entomology, paleobiology, mineral sciences, science and technology, arts and manufactures, civil history, and armed forces history).

The Bureau of American Ethnology was established as a branch of the institution in 1879, when the various organizations doing survey work in the west united as the U.S. Geological Survey, and anthropological and ethnological research under the direction of John W. Powell, was transferred to the Smithsonian Institution. The bureau carried on studies of the American Indians and published monographs and reports of its researches. The river basin surveys became an active program of the bureau in 1945 when a unit was organized to salvage and preserve archaeological materials in the path of national flood-control, irrigation, hydroelectric, and navigation projects. In 1965 the bureau was amalgamated with the National Museum's department of anthropology to become the Smithsonian office of anthropology under the Museum of Natural History.

Astrophysical Observatory.—In 1887 Samuel P. Langley (*q.v.*) was appointed as assistant secretary of the institution, and succeeded as secretary upon Baird's death in the same year. In 1890 Langley established the Smithsonian Astrophysical Observatory to carry on research on the physical aspects of the heavenly bodies, particularly the sun. Its early research concerned especially the measurement of the intensity and characteristics of the infrared solar rays. Langley developed the bolometer, an instrument capable of recording one-millionth of a degree of temperature. After 1900 the research concentrated on measuring the quantity and quality of the sun's radiation as it is found in free space at the earth's mean diameter. Field stations for solar observation were operated at several points in Africa, South America, and the United States. In 1955 Fred L. Whipple became director and the observatory moved its scientific headquarters to Cambridge, Mass. Its activities encompass the study of meteorites, the optical tracking of artificial earth satellites, the planetary and lunar sciences, exobiology, cometary science, and solar and stellar observations. In 1965 the observatory's division of radiation and organisms was accorded full Smithsonian bureau status, becoming the radiation biology laboratory.

National Zoological Park.—By acts of Congress of March 2, 1889, and April 30, 1890, the National Zoological Park was established under the institution. In a wooded area of 175 ac. in the valley of Rock Creek in Washington, D.C., the institution installed a small collection of animals that later grew to be one of the foremost collections of its kind in the United States.

Art Collections.—Upon her death in 1903, Mrs. Harriet Lane Johnston left her art collection to a national gallery of art, when such a gallery should be established. In 1906 the Supreme Court of the District of Columbia decreed that the art collection of the Smithsonian Institution was a national gallery, and turned the bequeathed collection over to it. It was later renamed the National Collection of Fine Arts. Housed in the Smithsonian's natural history building, the gallery attracted gifts of great interest and value, including the Ralph Cross Johnson collection of old masters, the William T. Evans collection of paintings of American artists, and the John Gellatly collection of paintings, glass, jewels, and antiques. The gallery also directs a Smithsonian traveling exhibition service.

In 1907 Charles Doolittle Walcott, eminent geologist and paleontologist, was elected secretary. During his administration of almost exactly 20 years the outstanding event for the Smithsonian was the receipt of the gift by Charles L. Freer of Detroit, Mich., of the Freer Gallery of Art, together with a large testamentary endowment. The Freer gift comprised more than 9,000 pieces, including works of American artists, especially James A. McNeill Whistler, Dwight W. Tryon, Abbott H. Thayer, and T. W. Dewing, and of Japanese and Chinese masters, including precious screens, ceramics, and bronzes.

A major event of the 1930s was the establishment of the National Gallery of Art, the gift of Andrew W. Mellon (*q.v.*) to the American people, as a bureau of the Smithsonian.

Further Developments.—In 1928 Charles Greeley Abbot, astrophysicist and assistant secretary of the Smithsonian from 1918, was elected secretary. He continued the researches begun by Langley on the variation of the sun's radiation, improving instruments and methods and establishing three solar observatories in widely separated regions of the earth.

Abbot was succeeded in 1945 by Alexander Wetmore, eminent zoologist, whose administration was marked by the addition of two bureaus to the Smithsonian organization, both in 1946—the National Air Museum, created by Congress to collect, preserve, and display aeronautical equipment of historical interest and significance; and the Canal Zone Biological Area, a 3,000-ac. jungle-covered reserve on Barro Colorado Island, C.Z., where a wide variety of biological studies are conducted.

Leonard Carmichael, psychologist, became secretary in 1953. Under his leadership two Smithsonian programs were notably advanced—an extensive project of renovating and modernizing museum exhibits; and a long-term program to provide new buildings for the growing institution.

During this period also, two additional Smithsonian bureaus were authorized by Congress: the National Cultural Center (1958), later renamed the John F. Kennedy Center for the Performing Arts, which, like the National Gallery of Art, operates under a separate board of trustees; and the National Portrait Gallery (1962).

In 1964 S. Dillon Ripley, ornithologist, became the eighth secretary of the Smithsonian.

The annual total number of visitors to the Smithsonian, including all its buildings, approximates 20,000,000.

The Smithsonian Park occupies an area in Washington, D.C., equivalent to about 12 city blocks. The oldest building, that of

the institution proper, was erected in 1847–55. It is of Seneca brownstone in a mingled Gothic and Romanesque style, designed by James Renwick (*q.v.*), and is located in the southwestern part of the grounds. Southeast of it is the arts and industries building, erected in 1881; on the north side of the park is the natural history building (1911). Southwest of the original Smithsonian building is the Freer Gallery of Art (1921). The monumental National Gallery of Art building (1941) faces on the Mall and Constitution Avenue, between Fourth and Seventh Streets, NW.

Early in 1964 a monumental new building for the Museum of History and Technology, erected directly west of the natural history building, was opened to the public.

In 1965 the Institution celebrated the 200th anniversary of the birth of James Smithson, the founder, with appropriate programs and ceremonies.

Publications.—The institution conducts an extensive publication program and has issued and distributed throughout the world more than 10,000 scientific books and monographs, in the following series: *Annual Reports* (1846 *et seq.*), in which the *Reports* of the National Museum were included until 1884, after which the museum *Reports* appeared as separate volumes; *Smithsonian Contributions to Knowledge* (1848–1916); *Smithsonian Miscellaneous Collections* (1862 *et seq.*); *Proceedings of the United States National Museum* (1878 *et seq.*); *Bulletins of the United States National Museum* (1875 *et seq.*), containing larger monographs than those printed in the *Proceedings*, and including *Contributions From the United States National Herbarium* (1890) and *Contributions from the Museum of History and Technology* (1959); *Annual Reports of the Bureau of American Ethnology* (1880 *et seq.*); *Bulletins of the Bureau of American Ethnology* (1886 *et seq.*); *Publications of the Institute of Social Anthropology* (1944–1953); *Annals of the Astrophysical Observatory* (1900 *et seq.*); *Smithsonian Contributions to Astrophysics* (1956 *et seq.*); *Catalogues of the National Collection of Fine Arts* (1922 *et seq.*); *Smithsonian Annals of Flight* (1964 *et seq.*); *Oriental Studies of the Freer Gallery of Art* (1933 *et seq.*); *Freer Gallery of Art Occasional Papers* (1951 *et seq.*); *Ars Orientalis* (1954 *et seq.*), sponsored jointly by the Smithsonian Institution and the University of Michigan; and many special publications.

SMITHSONITE, a mineral consisting of zinc carbonate, an ore of zinc which was formerly, until sphalerite (*q.v.*) began to be used in the 1880s, the principal source of all zinc produced (*see* also Zinc). In England smithsonite is known as calamine (*q.v.*). The formula of smithsonite is $ZnCO_3$. It crystallizes in the hexagonal system and is a member of the calcite group. Crystals are rare; it occurs usually in crusts or botryoidal masses. A porous variety is called dry-bone ore. The hardness is 4 to 4.5, and the specific gravity is 4.43 for the pure material, but varies with isomorphous replacement of the zinc by iron, manganese, calcium, and magnesium. The colour of the pure mineral is white, but it is more often brownish and sometimes green or blue; a bright yellow variety containing some cadmium sulfide has been found in Arkansas and is known as "turkey-fat" ore. It is a secondary mineral, formed by the action of ground water containing carbon dioxide on primary zinc minerals. It is frequently associated with hemimorphite, sphalerite, and galena.

Smithsonite occurs in Silesia and the Rhineland (Germany); Sardinia (Italy); Laurium, Greece (a translucent blue-green variety); Santander, Spain; Missouri, New Mexico, Utah, Colorado, Montana, and other localities in the United States; and in Algeria, Tunisia, Zambia (Northern Rhodesia), and Tsumeb, South West Africa. The mineral was named after James Smithson, the founder of the Smithsonian Institution. (L. S. Rl.)

SMOKE: IN WARFARE. While smoke has been one of the symbols and signs of warfare from earliest times, it was usually fire—rather than its by-product, smoke—that was dreaded by ancient armies in the field. Among primitive warriors, the American Indians had learned to employ smoke as an adjunct to military activity. They developed a visual signaling system of ascending smoke puffs that could be seen and interpreted by friendly tribesmen at considerable distances. Up until World War I, however, the use of smoke for tactical purposes was confined to special situations and was produced by improvised methods. It was during World War I that smoke and other chemical munitions had their inception on a standardized basis on the battlefields of Belgium and France. Later the employment of smoke munitions in warfare became recognized doctrine in all armies. In military operations smoke is used to advantage by ground, air and naval forces either on the offensive or on the defensive. Its main purposes are screening and signaling.

Screening Smokes.—For tactical purposes, smoke clouds are formed by firing smoke shells, dropping smoke bombs, burning smoke pots or operating mechanical smoke generators. These clouds are made up of masses of tiny particles that remain suspended in the air and hence produce an obscuring curtain. The behaviour of the smoke is dependent on wind and other natural factors, but the mechanical agencies that are used to create the clouds give them certain initial characteristics. Smoke created by a bursting shell, for instance, is released instantaneously and quickly forms into an expanding, rising puff. Smoke pouring from a continuing source, such as smoke pots, generators and burning-type shells, on the other hand, rises in a long, unbroken stream and remains effective for a much longer time. In deciding on the use of smoke under a given tactical situation, the commander must be thoroughly familiar with the prevailing natural conditions of the area in which the target is located and know the possibilities and limitations of the smoke munitions immediately available to him. Otherwise, the employment of smoke might revert to the advantage of the hostile forces.

While the direction and the velocity of prevailing winds exert the major effect on released smoke, humidity and the nature of the terrain also have a bearing on its behaviour. As might be expected, the obscuring power and effective duration of smoke is enhanced under conditions of high humidity. Ordinary ranges of temperature encountered in the field, however, have no perceptible effect. Level and unbroken terrain is reflected in a more evenly spread obscuring cloud above it, whereas smoke over hilly and broken terrain is less predictable because of the prevalence of inconsistent and erratic wind directions and speeds in such areas. In wooded regions smoke clouds persist longer and tend to cling to the treetops. Ordinarily smoke will follow ravines and defiles that crease the terrain in target sectors. Chemical shells produce smoke of varying properties that help overcome, or at least minimize, many of the screening handicaps inherent in the prevailing natural conditions of the battleground. Whenever smoke is used there is need for adequate observation and close co-ordination so that gaps and bare spaces that occur in the curtain can be readily repaired by directing artillery to fire smoke-producing munitions to the proper sectors of the target.

Individual soldiers and military units of all sizes have some means at their disposal for producing smoke. Smoke-producing munitions include the hand grenade and rifle grenade designed for the use of the individual soldier. Shells are made for firing from mortars, howitzers and guns. In the U.S. army, they range in size from those fired by 4.2 in. mortars up to the big 155 mm. guns and howitzers (and even larger calibres) used by the ground forces. Airplanes use either smoke generators or bombs when assigned to screening missions. Generator-produced smoke establishes long, low-hanging, persistent curtains and can be used over water as well as land areas. Naval vessels are equipped with smoke generators to provide smoke curtains for self-concealment.

The most widely used chemical agent in smoke-producing artil-

lery shells is white phosphorus. This chemical is inert when sealed in airtight jackets but burns and produces billows of dense white smoke when the shell bursts and the contents are exposed to the atmosphere. Special petroleum oils, heated and mixed with steam, are the smoke-producing agents used in mechanical smoke generators.

In tactical situations, smoke has many purposes that result in reducing casualties, saving matériel and speeding up operations in favour of the using forces. Its most important functions are to (1) blind hostile observation; (2) reduce effectiveness of enemy fire power; (3) hamper and confuse enemy operations; and (4) deceive the foe regarding the user's tactical preparations. Field tests and combat experience prove that the fire from troops enveloped by smoke is tremendously less effective than that from troops aiming into it. As a consequence, an attacking force can develop an advantage by firing smoke shells directly on hostile defensive positions both before and during an assault. This will not only minimize enemy fire power but will cause confusion among his troops. At the same time smoke conceals from enemy observation the size, deployment pattern, armament and movement of the advancing forces so that they achieve a certain degree of surprise in the attack. This is particularly important in assaults on strong points such as caves, dugouts, bunkers, pillboxes and machine gun emplacements where success is dependent upon getting close enough to the target so that flame throwers or hand grenades can be used effectively. Before the introduction of modern smoke munitions, attacking forces were obliged to rely on the natural concealment of night and early dawn to create similar advantages.

In the rear areas as well as in the combat zones smoke screens are used to conceal vital targets from observation and air attack. Troop concentrations, supply dumps, ports, communication centres, towns and industrial areas can be given this screening security in both daylight and darkness. If the strategic situation indicates the need, smoke curtains can be maintained continuously in friendly locations over periods of weeks or even months by the use of mechanical generators. Smoke screens are sometimes used for deceptive purposes. Spread over strategically valueless areas, they divert enemy attention from real targets and tend to draw wasted fire or useless bombing.

Signal Smokes.—Smoke munitions used for signaling or marking purposes contain organic dyes mixed with the basic burning chemicals which produce coloured smoke clouds. These clouds are visible for miles in good weather. Smoke-signal munitions come in a variety of colours, each having its own significance. By using different colours or combinations of colours, almost any type of information concerning objectives can be conveyed to friendly forces deployed over wide areas. Coloured smokes are most frequently used to mark targets, to signal the need of specialized attack on specific objectives, to announce the time for attack and to call for artillery fire.

Artillerymen often use signal-smoke shells for registering fire on targets. Smoke signals are also used to indicate rallying points and assist members of units in getting oriented in difficult terrain during the heat of battle. In joint air and ground operations, troops use coloured smoke signals to identify themselves and their positions to friendly aircraft. For the use of the individual soldier, coloured smoke chemicals are contained in hand and rifle grenades. They are also used in various sizes of artillery shells as well as in smoke pots.

SMOLENSK (SMOLENSKAYA OBLAST'), an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., was formed in 1937. Area 19,266 sq.mi. (49,900 sq.km.). Pop. (1959) 1,142,969. The greater part of the *oblast* lies in the basin of the upper Dnieper (Dnepr), which rises in the north. The eastern part drains to the Volga, the northeast directly, the east by the Ugra and Oka. The northwestern part drains to the Zapadnaya (Western) Dvina, which crosses the extreme northwest tip of the *oblast*. This close conjunction of three major river basins, flowing to three different seas, and the easy portages between them have made the area a focus of routes since earliest times. The main relief feature is the Smolensk-Moscow Upland, a ridge of terminal moraines, which crosses the *oblast* from east to west, just south of the Dnieper. It rises to 1,050 ft. (320 m.) northwest of Vyaz'ma. Between the confused morainic hills and ridges are broad valleys and depressions, often occupied by peat bog or grass marsh. The climate is continental, but much modified by Atlantic influences brought in by depressions from the west. The January average temperature is −7.7° C (18° F) and the July average 17.2° (63°). Rainfall is 22–26 in. (560–660 mm.) a year, with a summer maximum. The whole *oblast* lies in the zone of mixed forest, with a natural vegetation of pine, spruce, oak, and birch. The area has long been settled by Russians and the forest, once covering the whole surface apart from the swamps and natural meadows along the rivers, has been greatly reduced and now occupies about 18% of the *oblast*. Timber cutting is now restricted. Soils are mostly sod-podsols, weakly or moderately podsolized. Where sandy glacial soils occur, they are usually in pine forest.

Of the 1959 population, the low proportion of 32% was urban. Apart from Smolensk (*q.v.*; 147,196), the 14 towns and 7 urban settlements are small. The most significant are the rail junctions of Vyaz'ma in the east and Roslavl' in the south. In these three towns most of the industry, especially engineering, is concentrated. Many of the industries of the *oblast* are long-established, and have grown from small-scale enterprises: linen making, timberworking, glassmaking (mostly in the south), and food processing, especially cheese and butter making. Some lignite is mined at Safonovo. Much peat is dug for fuel. Agriculture is dominated by flax growing, for which Smolensk is the second most important *oblast* of the R.S.F.S.R. Rye and oats are the chief grains, although some wheat and maize (corn) are also grown. Potatoes are important and used for human and animal consumption, distilling, and starch making. Dairy farming is highly developed, helped by the abundant natural pasture, although sown grasses occupy over a quarter of the arable land.

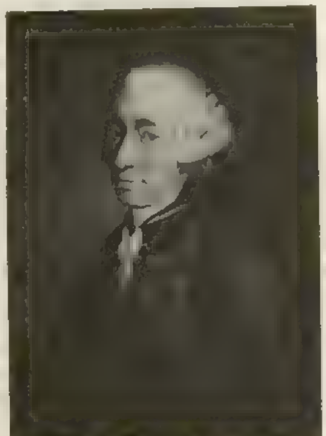
(R. A. F.)

SMOLENSK, a town and *oblast* centre of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on both banks of the Dnieper (Dnepr), 260 mi. (418 km.) WSW of Moscow. Pop. (1959) 147,196. Smolensk is one of the oldest and most historic of Russian towns, dating back to the 9th century, but the ravages of war (particularly World War II) have left little of the many ancient churches and other buildings. Among those surviving and now restored are the 12th-century churches of SS. Peter and Paul, the Svirskaya (1191–94), and St. John the Divine (1173–76). Modern Smolensk is a key junction on the main Moscow-Warsaw railway and highway, on the navigable Dnieper, and on other railways to Vitebsk and the northwest, to Bryansk and the south, and to Sukhinichi and the southeast. It has engineering industries, concerned with vehicle and tractor repair equipment and textile machinery, and also linen making. Other industries include timber working; the manufacture of glass, bricks, clothing, knitwear, and shoes; flour milling; and other food industries. There are medical, veterinary, pedagogic, and physical training institutes.

The first documentary mention of Smolensk is in 882, but it has been suggested that the adjacent burial ground of Gnezdovo, with nearly 4,000 tumuli, may be even earlier. Certainly Smolensk at a very early date was one of the leading Russian towns, deriving its importance from its control of the key portages between the Dnieper and the Zapadnaya (Western) Dvina. The town was thus the main centre of the middle section of the Baltic-Byzantium "Water Road." At first under Kiev, in 1054 the town was given to the fifth son of Yaroslav the Wise and later chose its princes by the *veche*, or town assembly. Trade with the west increased, especially in the 12th and 13th centuries, and in 1229 a trade treaty was signed with the Germans, which refers to a "Latin" church in the town. As usual in old Russian towns, there was a citadel, or kremlin, and a commercial town, both originally on the left bank. The Tatar invasion of 1238–40 sacked the town, and it subsequently passed to the Grand Duchy of Lithuania. For over four centuries Smolensk was the key in a bitter struggle between

Muscovy and the west. In 1340 it fell after a siege to the Muscovites; in 1408 another siege led to its capture by the Lithuanians. The year 1514 saw it recaptured by Moscow, and in 1596–1602 its kremlin was rebuilt by the architect Fedor Kon; but in 1610, in the "time of troubles," it fell to the Poles, after a 21-month siege. Only in 1654 was Smolensk finally captured by Russia (and formally ceded in 1686), but its position on the main route from Moscow to Warsaw and western Europe gave the town no peace. One of the major engagements of Napoleon's advance to Moscow in 1812 took place at Smolensk on Aug. 17–18 and the town was burned. During the retreat Napoleon stayed there for four days in a vain attempt to rally his army. From July to September 1941 one of the bitterest battles of World War II was fought in and around Smolensk, preventing the Germans from occupying Moscow. In October 1943 another great battle forced the Germans to abandon the town. (R. A. F.)

SMOLLETT, TOBIAS GEORGE (1721–1771), Scottish novelist who combines realistic description of the life of his age with satire on the folly, selfishness, and cruelty of mankind, was born in March 1721, near Cardross in Dunbarton. His father, who died soon after Tobias' birth, belonged to a distinguished family notable for its pride, its resourcefulness, and its independence. The Smolletts were Whigs in politics and Presbyterians in religion, and had a strong traditional connection with the law. Smollett was sent to Dumbarton Grammar School, memories of which no doubt lie behind some of the graphic descriptions of schooldays in *Roderick Random*—perhaps the ferocity of the punishments, for example, and the violence of the practical jokes. He was then apprenticed to two well-known Glasgow surgeons and attended classes at the university, before setting out for London at the age of 18, burning with desire to see his tragedy, *The Regicide* (publ. 1749), produced in the metropolis—a desire destined never to be fulfilled.



PORTRAIT BY AN UNKNOWN ITALIAN ARTIST; PHOTO, BY COURTESY OF THE NATIONAL PORTRAIT GALLERY

TOBIAS SMOLLETT, ABOUT 1770

It is unfortunate that little is known about the next few years, since Smollett anticipated later "realistic" writers in often using his own experiences in his books with relatively little modification; but it is clear that he gained experience of life in London, in the navy, and in the West Indies. The description of the tragic expedition to Carthagena in *Roderick Random* is comparable with Goya's etchings of scenes of warfare. In 1742 or 1743 he married a Jamaican heiress, Anne Lassells, who was to outlive him by 20 years; and soon after he took up his residence in London.

It is significant that Smollett's first considerable publications, apart from journalism and the fine lyric "The Tears of Scotland" (written after the defeat of Charles Edward at Culloden on April 16, 1746), should have been *Advice* (1746) and *Reproof* (printed with *Advice*, 1748), two Juvenalian satires; for there is a marked element of satire in all Smollett's work—not the satire of an unfeeling man (in spite of its harshness), but rather that of a sensitive observer whose nerves are shocked by the brutality and selfishness of human life. That Smollett should then have turned to the novel as a form of expression is not surprising: this was the decade following Defoe's death, the decade that saw the first work of Samuel Richardson and Henry Fielding. There was a strong tide running in favour of prose fiction, a tide which carried *The Adventures of Roderick Random* (1748) to immediate success. The preface makes it clear that Smollett's conception of the novel was much less lucid and classical than that of Fielding: the three main terms which Smollett uses—"satire," "romance," and "comedy"—are not clearly related to each other. What the book gives us is simply a narrative in the first person describing a number of vivid and characteristic scenes of contemporary life, tempered by some severe satire on the folly and cruelty of mankind. Except in *The Expedition of Humphry Clinker* (1771) there is no real unity in Smollett's books: he uses as his protagonist the *picaro* of Spanish tradition, a young man as resilient as a rubber ball who is unencumbered with principles or ideals. The value of *Roderick Random* lies in the powerful truth to life of individual scenes, particularly those describing the violent and squalid life of the 18th-century navy.

Smollett translated Le Sage's *Gil Blas* in 1748 and made a journey to France in 1750, probably to collect material for *The Adventures of Peregrine Pickle* (1751), which is written in the third person but which resembles *Roderick Random* in the power and humour of its individual scenes as it does in its lack of general structure. The description, in the first volume, of Peregrine's colourless father and his remarkable friend Commodore Trunnion, with his faithful Lieutenant Hatchway, is an incomparable piece of humorous writing which gave a hint to Sterne for Uncle Toby and his "garrison" in *Tristram Shandy*. The protagonist, for all the "modest merit" attributed to him, is an even greater scoundrel than Roderick Random: he deserves a long spell in prison rather than the heiress with whom he is rewarded at the end of the book.

In his remaining 20 years Smollett wrote a great deal, much of it hackwork of little interest today. His writings include *A Complete History of England, Deduced from the Descent of Julius Caesar to the Treaty of Aix La Chapelle, 1748* (four volumes, 1757–58), the *Continuation of the Complete History of England* (five volumes, 1760–65), and numerous translations, as well as the *Travels Through France and Italy* (1766) which annoyed Sterne and helped to produce *A Sentimental Journey*. He wrote an immense amount of journalism and edited *The Critical Review* from 1756 to *c.* 1762. Three minor works of fiction deserve mention: *The Adventures of Ferdinand Count Fathom* (1753), *The Adventures of Sir Launcelot Greaves* (serialized 1760–61; 1762), and *The History and Adventures of an Atom* (1769). Derivative as these books are, here and there in them Smollett anticipates later developments in popular prose fiction. But *Humphry Clinker* is his masterpiece. It consists of letters written by the various members of a family who are making a tour of Britain: an idea that Smollett probably took from Christopher Anstey's *New Bath Guide* (1766—a series of poetical letters sent by an imaginary family to friends in the country). In the early chapters (particularly) of *Humphry Clinker* humorous effect is gained from the contrasting impressions made by Bath on a romantic young girl and a testy valetudinarian; but later Smollett concentrates on describing the places which his travelers visit and on the opportunities that arise for satirical comment on human life. The romantic plot is no more than a thread on which to hang the "humours" of old Matthew Bramble, who is well described by his nephew when he says that he "affects misanthropy, in order to conceal the sensibility of a heart, which is tender, even to a degree of weakness." Through the *persona* of Bramble (a Welshman) Smollett is able to pay tribute to his native Scotland, from which he had been exiled for most of his life but which he had revisited as an ailing man in 1766.

In December 1769 he went to Italy in search of health, and in 1770 settled near Leghorn, where he died on Sept. 17, 1771—the same year that saw the birth of a greater Scottish novelist, Sir Walter Scott, who was destined to be both the admirer and the biographer of Smollett.

BIBLIOGRAPHY.—*Works:* No edition exists which includes reliable texts of all his writings, and there is no collection of most of his journalism. Of "collected" editions, *see* those by R. Anderson, 6 vol. (1796; with enlarged *Memoir*, 1800); J. Moore, 8 vol. (1797); W. E. Henley and T. Seccombe, 12 vol. (1899–1901); and G. M. Maynadier, 12 vol. (1902). There is an edition of the novels by G. Saintsbury, 12 vol. (1895); and an Oxford edition, 11 vol. (1925–26). There is an unexpurgated edition of *Peregrine Pickle*, by J. L. Clifford (1964). *Humphry Clinker* was ed. by L. M. Knapp (1966). *Travels Through France and Italy* was ed. by T. Seccombe (1907). The *Plays and Poems* were collected in 1777. The *Letters* were ed. by E. S. Noyes (1926).

Biography and Criticism: Sir Walter Scott, in *Lives of the Novelists*, 4 vol. (1821–24; ed. by G. Saintsbury, Everyman's Series, 1910); H. S. Buck, *A Study in Smollett, chiefly "Peregrine Pickle"* (1925); G. M. Kahrl, *Tobias Smollett, Traveler-Novelist* (1945); L. M. Knapp, *Tobias Smollett, Doctor of Men and Manners* (1949); R. Alter, *Rogue's Progress: Studies in the Picaresque Novel* (1964). (I. J.)

SMUGGLING, the conveyance of things by stealth, is particularly applied to the clandestine movement of goods to evade customs duties or import or export restrictions, but may include the secret movement of persons.

Smuggling flourishes wherever there are high revenue duties (*e.g.*, on tea, spirits, and silks in 18th-century England, coffee in many European countries, and tobacco almost everywhere) or prohibitions on importation (narcotics) or on exportation (arms and currency). The most convenient commodities to smuggle are high-value goods of small bulk such as watches or drugs. Some geographical conditions favour smuggling, particularly a long coastline or remote land frontiers, or the proximity of a fiscally favoured territory as a base. The Isle of Man was such a threat to England until 1765, as was Gibraltar to 19th-century Spain; Hong Kong, Macao, Goa, Andorra, and Tangier are other examples of free or low-duty enclaves which have endangered the revenue security of their neighbours.

History.—Smuggling is probably as old as the first tax or regulation on trade. England, which was the first modern nation to develop a national system of finance and a professional customs force, has been particularly prone to both commodity and currency smuggling from the end of the 13th century onward. Other European nations retained the seigneurial system much later than England, their monarchs being financed by domain fines or fees, with little reliance on customs taxation. In America, however, the customs system grew up with the Colonies and was adapted to benefit the nation after Independence.

In the late 17th century smuggling was greatly encouraged by a technical development in the rigging of cutters, which enabled vessels to sail in and out on more or less any wind, and by wars on the European continent whose cost forced up the rates of customs duties.

In the early 1700s England secured the right to send one ship a year to the Spanish-American colonies. This was the pretext for much smuggling. Actions between Spanish coastguardsmen and English traders led to the "War of Jenkins' Ear" in 1739 (*see* JENKINS, ROBERT). The 18th century became the heyday of the smuggler, and smuggling in England became so serious as to threaten the structure of finance and government. Wool continued to be smuggled to the European continent, and tea, tobacco, spices, silks, and spirits were smuggled into England in quantities exceeding the legitimate trade. English popular opinion sided with the "free traders."

In France smuggling against the tobacco monopoly and the exorbitant gabelle (*q.v.*) on salt became widespread. For the protection of the farmers-general, severe penalties were imposed which sent 3,000–4,000 persons every year to prison, the galleys, or the gibbet. During the Napoleonic Wars, English smugglers were paid by the French to break the British blockade. After Waterloo, when the European armies were discharged, smuggling grew to alarming proportions. The English army and navy were called in to maintain an expensive blockade until, after much violence, the illicit trade was suppressed, while the fiscal policy of free trade helped to prevent its immediate recurrence.

Britain could not enforce its policy of requiring its colonies to trade with the rest of the world only through the mother country: by 1744, more than 40 vessels from American colonies were trading direct at Hispaniola. Many convicted English smugglers were transported to British colonies where they found opportunities to ply their trade. Spain's trade with her colonies had been strictly regulated, but was interrupted by wars, and Mexican and Peruvian merchants began to rely upon smugglers. Jamaica became the centre of the Caribbean smuggling trade. In spite of the Molasses Act of 1733, American merchants got their supplies direct from French and Dutch possessions in the vicinity. The burden of the British revenue and mercantile laws fostered independence; from the large-scale smuggling of tea it was only a short step to the Boston Tea Party, which repudiated the whole customs system. After Independence, smugglers such as Jean Laffite (*q.v.*) were active on the Louisiana coast, but during Jefferson's Embargo and Non-Intercourse acts the centre of illicit activities shifted to the North.

Attempts by the Chinese government to stop the smuggling of opium led to the opium war of the 1840s and the ceding of Hong Kong to Britain. Despite its illegality Englishmen and Americans continued to smuggle opium from India into China in exchange for tea and silks. When the trade was legalized, the import duty was so high that smuggling continued into the 20th century. British India in the 19th century suffered smuggling of salt between the different states with varying tax rates, while smuggling of all kinds of dutiable goods occurred between Goa and India and between Gibraltar and Spain.

Throughout the 19th century a contraband traffic in African slaves persisted. In the 1830s, after most civilized nations had declared the trade illegal, as many as 135,000 Africans were being enslaved each year, and mostly carried to Brazil, the United States, and Arabia. The British navy endeavoured to suppress this traffic around African coasts. The Atlantic slave trade reached a peak in its last years before the American Civil War. "Blackbirders" ran Negroes into the South; the Underground Railroad (*q.v.*) spirited some slaves northward to freedom. In the Middle East the illegal slave trade continued into the 20th century. (*See* also SLAVERY: *International Efforts to Suppress Slavery Throughout the World.*)

In the latter half of the 19th century smuggling developed in Africa, particularly of spirits from the Portuguese colonies into the Boer states and from French colonies into the Gold Coast and Nigeria. Illegal supplies of arms and ammunition were also poured into Africa and New Zealand. Another problem of the period was the white-slave traffic, or smuggling of girls abroad for prostitution, which was checked only by international agreements, leading to control by the United Nations in the 20th century. Fortunes were also made in the traffic in obscene publications during this period, and this trade revived in the decades after World War II.

20th Century.—In the 20th century smuggling against revenue duties has been overshadowed by smuggling of prohibited goods. International syndicates trade in narcotics, arms, diamonds, bullion, and illicit currency. The 13 years of prohibition (*q.v.*) of liquor in the United States from 1920 presented such opportunities to smugglers that violations threatened to overwhelm the authorities in conditions reminiscent of 18th-century England. Fleets of craft laden with liquor left Europe and the West Indies for the Atlantic coast, while truckloads were run all along the Canadian frontier (*see* also BOOTLEGGING). Prohibition was also tried in Finland, Norway, and Sweden; spirits were prohibited in Belgium. The smuggling syndicates were so successful that in Finland, for instance, there was never any real shortage of liquor. Smuggling scandals in Canada involving members of the customs department precipitated the resignation of the prime minister, William Mackenzie King, in 1926. In the 1920s and 1930s guns were smuggled into Ireland, Spain, and the Middle East.

In the period following World War II, there was an abundance of money but great shortages of goods varying between one country and another. Currency restrictions prevented free purchase and encouraged a return to barter in Europe, coffee and cigarettes becoming a common form of currency. As after the Napoleonic Wars, there were numbers of adventurous ex-servicemen and former resistance fighters well trained in movement by stealth: fast ex-naval motorboats could be had cheaply. Perhaps the worst smuggling was into Italy by sea and land, and over the land frontiers between France and Belgium and Germany. The principal goods smuggled were tobacco (particularly into Italy where there is a state tobacco monopoly), watches into all countries from Switzerland, nylon stockings, and other portable manufactured goods. In spite of decreasing tariffs between the Common Market countries, butter smuggling from Holland to Belgium was still a problem in the 1960s, and cigarette smuggling continued into Italy, while Denmark was troubled by the illegal importation of cigarettes and cigarette papers. Shortages of consumer goods still occurred in the 1960s in some European countries through quota restrictions, and there were always smugglers ready to make good the deficiency.

Stringent currency restrictions imposed in the era after World

War II provided huge profits for international smuggling gangs. There was a great West-East movement of gold, as peasants of Asia would buy gold for hoarding at well above world prices. Licensed users of gold in the United States and other western countries evaded official restrictions and provided the source of the bullion smuggled into India and Pakistan. Currency was smuggled out of India to pay for the traffic. Valuable paintings (permission to export which might have been withheld) were smuggled from Italy and also from Britain, usually for sale in the United States.

Even if tariffs, quotas, and currency controls were abolished there would still remain some prohibitions on the free movement of goods. Many western countries prohibit the export of potential war material to unapproved destinations, but gunrunning to unstable countries continued to occur in the 1950s and 1960s, and some strategic material was diverted to the Soviet bloc or Communist China. Most countries restrict the import of narcotic drugs, but this enormously profitable traffic is most difficult to eradicate. In the United States, gangs which had flourished during Prohibition turned to dope smuggling, and in spite of international cooperation and some brilliant successes by the federal authorities the problem remained serious. In December 1964 New York customs officials seized cocaine worth over $1,000,000 coming from South America, the biggest single quantity of drugs till then intercepted in the U.S. since before World War II. The traffic existed also in Europe, where Italy had been shocked by its extent. (*See* also NARCOTICS, LAWS RELATING TO.)

Stolen diamonds were being smuggled out of the diamond fields of Africa to evade the monopoly of the Diamond Selection Trust and continued through illicit channels to Europe, America, and Russia. The mining Diamond Corporation created the Independent Diamond Security Organisation to combat the leakage.

Methods of smuggling change little; all are variants on two themes: the undetected "running" of cargoes across frontiers, or concealment in unlikely places on ships or cars or on the person or in baggage or cargo.

Countermeasures.—Countermeasures have a similar pattern in most countries. Current basic acts are: in the U.S., the Tariff Act of 1930, and the Anti-Smuggling Act of 1935; and in Britain, the Customs and Excise Act, 1952. Usually the law prohibits the import or export of goods except at approved ports or frontier crossings, where permanent customs staffs can control traffic. This must be backed by efficient patrol systems using fast craft and modern equipment such as radio or, in some countries, helicopters. There are laws against hovering off the coast or signaling to smugglers. Vessels must stop when challenged and may be fired upon if they fail to do so. The captain of a ship or aircraft must present a cargo list without delay. All this must be reinforced by legal powers of search of ships, vehicles, persons, and premises, powers to arrest offenders and to seize contraband goods and vehicles or craft carrying them. Severe legal penalties have been set as deterrents. In English-speaking countries, persons suspected of violating customs laws have fewer rights than common-law offenders. Passengers and crews must submit to questioning and may be searched without special warrant. A claimant seeking to recover seized goods carries the burden of proof that duty has been paid. (*See* also COAST GUARD: *United States*.)

Because successful smuggling is undetected smuggling, no firm estimate is possible of the extent of evasion. The profits, however, are such as to tempt men into smuggling. An increase in the number of seizures may point to an increase in smuggling, but it may be due to improved methods and efficiency of the administration. Any comparison of the number of convictions secured by different countries must take account of the extent of legitimate trade. For instance, U.S. Treasury Reports for the decade after World War II showed a yearly average of about 400 convictions for revenue offenses, but at the same time more than 22,000,000 ships, aircraft, and other vehicles and almost 90,000,000 persons entered the United States in an average year. The figure of convictions is but a tiny fraction of the traffic. A European table of major customs convictions showed Britain at the head with 93 in the years 1955–64, followed by Austria with 85. Whereas the British figures are fairly evenly spread over the ten years, the major convictions for some countries (including Spain, Portugal, and France) all occurred in a single year.

SMUT AND BUNT, parasitic fungus diseases of various flowering plants, especially cereals and other grasses. Smuts and bunts compose the order Ustilaginales of the class Basidiomycetes. The name smut refers to the black or brownish powderlike masses of fungus spores that commonly appear in the flowers or heads, but in some cases on the stems, leaves or even roots, of host plants. The smut fungi usually give little if any evidence of their presence in the host prior to spore formation. In some cases the fungus mycelium causes hyperplasia (increase in cell division) or hypertrophy (abnormal enlargement of existing cells) of the host, resulting in galls or tumours as exemplified in corn smut. The smuts in general are best typified by the genus *Ustilago*, species of which attack oats, barley, wheat, corn, etc. The loose and covered smuts (in the former the membrane enclosing the infected grain ruptures; in the latter it does not) which destroy the inflorescence of cereals are among the best known of the *Ustilago* types.

Bunt indicates a special group of the inflorescence smuts, caused by species of *Tilletia*. The bunts, or stinking smuts, so called because of their characteristic and unpleasant odour of decaying fish, are best exemplified by the bunt of wheat (*Tilletia caries* and *T. foetida*), a classical disease of plant pathology. The bunt fungi invade the host when the latter is in the seedling stage. Their mycelia ramify and grow harmoniously with the host plant to its maturity. At this point the presence of the fungus is detected as it sporulates in the wheat head and completely replaces the grain with powdery masses of black spores.

The principal means for controlling most smuts is by seed treatment, either with chemicals or heat. Soil treatment, the use of resistant varieties and the adoption of certain cultural practices are other important control measures. Seedling-infecting smuts usually are controlled by various chemical seed treatments. The embryo-infecting loose smuts of wheat and barley may be checked by the hot-water or water-soak treatment of seed or by the use of certified smut-free seed.

The economic importance of smut fungi becomes apparent when it is realized that cereals constitute 73% of the total food consumed by man, and that smuts are one of the most important and widely studied groups of cereal diseases. In the Pacific northwest region of the U.S., where wheat bunt has always been a serious problem, the average annual loss attributed to bunt in the five-

year period 1951–55 was $4,500,000. The loose and covered smuts of barley, wheat and oats constantly threaten these cereal crops, especially where they are grown in the more humid or irrigated regions of the world. Annual losses attributable to corn smut in the U.S. have run as high as 55,000,000 bu.

See FUNGI: *Basidiomycetes* (*Club Fungi*).

A bibliography pertaining to the smut fungi may be found in G. W. Fischer and C. S. Holton, *Biology and Control of the Smut Fungi* (1957). (E. L. KE.)

SMUTS, JAN CHRISTIAAN (CHRISTIAN) (1870–1950), South African statesman, soldier and philosopher, was prime minister of the Union of South Africa from 1919 to 1924 and again from 1938 to 1948. His greatness lay in his continuous pursuit of Anglo-Afrikaner unity in South Africa, his reconciliation of Dominion autonomy with Commonwealth cohesion, his contributions to international order and his vigorous leadership in World Wars I and II. He was born on the farm Bovenplaats, near Riebeeck West, Cape colony (Cape of Good Hope), on May 24, 1870. Both parents were Afrikaners, his father, Jacobus Abraham Smuts, being a farmer and a member of the Cape parliament. At the Riebeeck West school, where he was for a time a fellow student with his later political adversary Daniel François Malan, at the Victoria college, Stellenbosch, and at Christ's college, Cambridge, Smuts stood out as a student of great ability, with a mind that was both broad and deep. In 1894 he was top of the first class in both parts of the Cambridge law tripos: and in England he also wrote a psychological study based on the life and work of Walt Whitman, but failed to find a publisher for it. He took practically no part in the social life of his fellow students.

JAN CHRISTIAAN SMUTS, ABOUT 1943

Early Career.—On his return to South Africa in 1895 he practised at the Cape Town bar and supplemented his income by working as a political journalist. At first he supported Cecil Rhodes, prime minister of Cape colony, whose declared aim was Anglo-Afrikaner co-operation and the development of South Africa under Cape leadership. The raid of L. S. Jameson (*q.v.;* Dec. 1895), however, destroyed his confidence in Rhodes and in 1897 he moved to Johannesburg, where a few months later he took his bride, Sybella Margaretha Krige, whom he had met while at college at Stellenbosch. In June 1898 Smuts became state attorney of the South African republic, hoping that, as other young Afrikaners came to the fore, the regime would become less corrupt and more progressive. But Joseph Chamberlain, the British colonial secretary, and Sir Alfred (afterward Viscount) Milner, the high commissioner for South Africa, were impatient to assert British supremacy throughout South Africa and to use the grievances of the Uitlanders to that end. (*See* SOUTH AFRICA, REPUBLIC OF: *History*.)

Smuts worked for a peaceful solution to the Uitlander question, persuading Pres. Paul Kruger to offer considerable concessions to Milner at the Bloemfontein conference in June 1899 and himself offering further concessions to Conyngham Greene, the British agent at Pretoria, in August. When the negotiations collapsed and war broke out in October (*see* SOUTH AFRICAN WAR), Smuts devoted all his energy to the struggle for the maintenance of the independence of the South African republic and its ally, the Orange Free State, producing a plan for the overthrow of the British empire and publishing *A Century of Wrong* (1899), a vitriolic attack upon British policy in South Africa. After the fall (June 1900) of Pretoria, the Transvaal capital, Smuts himself became a guerrilla fighter, leading a commando deep into the Cape colony to harass the British and foment rebellion. This experience demonstrated his leadership ability and won him the lifelong allegiance of those who served under him. April 1902 found him besieging O'okiep in Namaqualand, whence he was summoned to the conference of Boer representatives at Vereeniging (May). When he had heard reports on the military situation, and when Lord Kitchener, the British commander in chief, had told him that it was likely that the Liberal party would soon be in power in Great Britain and that it would give the former republics a form of self-government, he realistically concluded that it would be wise to come to terms with the British; and he was a negotiator and signatory of the treaty of Vereeniging (May 31, 1902).

Soon afterward Smuts entered into close co-operation with Louis Botha, his wartime commander in chief. They denounced the English language educational policy of Milner's crown colony government in the Transvaal and Orange River colony and the decision in 1904 to import Chinese labourers to the Witwatersrand gold mines, and in 1905 they founded a political organization *Het Volk* ("The People"). As soon as Sir Henry Campbell-Bannerman had formed a Liberal ministry (Dec. 1905) in Britain, Smuts hurried to London to urge the cabinet to give the Transvaal immediate self-government, with an electoral system favourable to the Boers. He succeeded. In March 1907 the Transvaal became a self-governing colony, with Botha prime minister and Smuts colonial secretary (later also minister of education).

Work for Political Union.—The conduct of the Liberal government confirmed Botha and Smuts in their belief that Britain was no longer an enemy but a friend. Thereafter they strove to put an end to the feud between Boer and Briton in South Africa by welding them into a new nation which, like Canada, Australia and New Zealand, was to be a willing partner in the evolving British Commonwealth. Smuts therefore framed an education act (1907) for the Transvaal which permitted Afrikaner children to be taught in the Dutch language to a much greater extent than under the crown colony regime, but was mild enough to reassure the Transvaal British. He also prepared the ground for the unification of the four self-governing British South African colonies—the Transvaal, the Cape colony, Natal and the Orange River colony. He used the breakdown of the railway and customs agreements between the colonies as the occasion for calling in Oct. 1908 a national convention to consider some form of political union. He then wrote the outline of a draft constitution for South Africa, sent copies of it to leading statesmen in the Cape colony and the Orange River colony, and amended it in consequence of their comments. Next he discussed it with members of the opposition as well as his colleagues in the Transvaal and, after further alterations, gained their approval. Smuts's modified plan was the basis of the document which was unanimously adopted by the national convention (May 1909), enacted without amendment by the British parliament, and brought into force as the constitution of the Union of South Africa (May 31, 1910).

In the first Union cabinet, as previously in the Transvaal cabinet, Botha was prime minister and Smuts his right-hand man. At the outset their South African National party (formed in 1910) had the support of nearly all the Afrikaner voters, but it soon suffered a serious setback. J. B. M. Hertzog, minister of justice, considered that Botha and Smuts were placing the interests of Britain and the empire above the interests of South Africa, and that their policy would result in the denationalization of the Afrikaner people. In 1912 Hertzog made a series of speeches criticizing their policy and Botha formed a new government without him. Two years later Hertzog founded the Afrikaner Nationalist party, with the object of preserving the identity of the Afrikaners as a nation within a dualistic white South African nation. The result was that as Hertzog weaned Afrikaner voters away from Botha's party, now named the South African party, Botha and Smuts came increasingly to depend upon the support of British South Africans.

World War I.—This trend was promoted by World War I. In Sept. 1914 the Botha government decided to act on a British request that South African troops should occupy German South West Africa. Many Afrikaners resented this decision and some of them rebelled (October). When the rebellion had been suppressed (December), Smuts took part in the conquest of South

West Africa and in 1916 he became commander in chief of the imperial forces in East Africa. He had nearly completed the conquest of Tanganyika when, in March 1917, he went to attend the imperial war conference in London. He remained there as a member of the imperial war cabinet and the British war cabinet, performing many valuable services for the British government and the allies. His speeches at that time stressed the importance of maintaining the cohesion of the Commonwealth on the basis of Dominion autonomy; and in Dec. 1918 he wrote a memorandum for the imperial war cabinet outlining the project of a League of Nations, which was a major contribution to the origin of that body. At the peace conference at Versailles, recalling his own position at Vereeniging, he opposed the imposition of severe reparations on Germany and it was with great reluctance that he signed the treaty of Versailles (June 28, 1919).

Prime Minister.—Botha died in Aug. 1919 and Smuts succeeded him as prime minister. By that time his international prestige was high. In 1921, besides attending the imperial conference in London, he persuaded some of the Irish leaders to enter into the negotiations which led to the Anglo-Irish treaty of Dec. 1921 and the establishment of the Irish Free State. But his political position in South Africa was difficult. The Nationalists gained ground in the 1920 elections and in the next year, rather than unite with them, Smuts's party joined forces with the Unionists, the party of most of the English-speaking South Africans, and gained an increased majority at the election of 1921. The effect of this amalgamation was reduced by industrial unrest on the Witwatersrand. As early as 1914 Smuts had suppressed a general strike of white mineworkers by proclaiming martial law and arresting and deporting the leaders. In 1922 another such strike developed into a large-scale rebellion; the rebels gained control of most of the Witwatersrand, and there were 700 casualties before Smuts in person restored order. He then tried to improve his political prospects by offering the voters of Southern Rhodesia favourable terms for incorporation in the Union, but when a referendum was taken in Oct. 1922 most of them preferred that Southern Rhodesia should become a self-governing colony, separate from the Union. In 1923 the Nationalists came to an agreement with the Labour party, whose main strength was among the Witwatersrand mineworkers, and in 1924, after a government defeat in a by-election, Smuts went to the country and was defeated by the Nationalists and their Labour allies. His exclusion from office enabled Smuts to complete a philosophical treatise, *Holism and Evolution*, which he had started many years earlier. Its publication in 1926 attracted the attention of philosophers throughout the world.

For some years the Nationalist government was secure, for the Afrikaners were a majority of the voters and they were assisted by an electoral system which favoured the rural areas. During the world depression which began in 1929, however, the government encountered difficulties through trying to remain on the gold standard after Britain had left it in 1931, and in 1933 Hertzog and Smuts formed a coalition government, with Hertzog prime minister and Smuts deputy prime minister. In 1934 the Nationalist and South African parties fused into the United party.

World War II.—Hertzog and Smuts co-operated successfully in internal matters, such as the enactment of segregation laws for Africans, and in completing the legal autonomy of the Union by the Status act of 1934; but they differed on how the Union should exercise its autonomy in foreign affairs. This difference came to a head when Germany invaded Poland in 1939. Hertzog considered that South Africa should remain neutral, but Smuts, sensitive to the broader implications of Nazi expansionism, disagreed. The cabinet split into two irreconcilable groups and the issue was debated in the house of assembly, which decided for Smuts by 80 votes to 67. On Sept. 5, 1939, Smuts formed a government with the support of the Labour party, the Dominion party, and a majority of the United Party, to wage war against Nazi Germany.

Notwithstanding widespread opposition to participation in the war, and a certain amount of sabotage, the South African war effort was impressive. South African troops played an important part in the Ethiopian, north African and Italian campaigns and South African industry was geared to the production of war materials. As prime minister, Smuts actively supervised the administration of the Union, and as commander in chief of the South African armed forces he paid several visits to the African and European theatres of war. He also kept in touch with other allied leaders, especially Winston Churchill, who set a high value on his judgment. In 1945 he attended the San Francisco conference, playing a major part in drafting the United Nations charter.

Postwar Years.—Smuts and his colleagues planned a progressive postwar program for South Africa, involving white immigration, industrial expansion and the improvement of agriculture; but after World War II, as after World War I, political forces in the Union were against him. In the 1943 election he had won a good majority, partly because the opposition had been splintered into several factions; but by 1948 Malan had consolidated most of the factions into his new Nationalist party, which exploited discontents caused by wartime controls and fears that white supremacy was being undermined. Continuous erosion of the tribal system by economic forces and the democratic ideology of the allies in World War II had promoted among the African people of the Union demands for the relaxation of segregationist measures. Smuts, without making any significant concessions to them, had adopted a conciliatory attitude. Malan and his party accused Smuts of endangering white supremacy and propounded the theory of *apartheid*, according to which the races were to be separated from one another and white supremacy was to be assured. The 1948 election resulted in a narrow but decisive victory for Malan and his Afrikaner party allies. Smuts was defeated in his own constituency, but a safe seat was soon found for him elsewhere. He was leader of the opposition when he died, on Sept. 11, 1950, at his home at Irene near Pretoria.

Smuts held many honours. He was a privy councilor (1917), a Companion of Honour (1917), and a member of the Order of Merit (1947); rector of the University of St. Andrews (1931–34) and chancellor of the University of Cape Town (1936) and of Cambridge university (1948); a British field marshal (1941); and he was awarded many honorary degrees and the freedom of many cities. Smuts's shortcomings were those of his background. To him the South African nation was essentially a white nation; he was never clear as to the role of the African, the Asian and the Coloured peoples in South African society. To him the Commonwealth was essentially an association of white nations: he could not fully reconcile himself to the admission of India, Pakistan and Ceylon as equals. To him the world order was to be based upon the continuing leadership of white nations.

His setbacks in South Africa arose out of his failure to carry his own Afrikaner people with him into the wider groupings of nation and Commonwealth. He might have been more successful if he had shown a keener insight into the mind of the ordinary Afrikaner farmer, and if he had been interested in Afrikaans literature. As it was, he was regarded by many Afrikaners as completely denationalized—an agent of the British South African and of British imperialism.

SMYRNA (ZMYRNA) was in later antiquity one of the principal cities of Asia Minor. Known in modern times by its Turkish name of IZMIR (*q.v.*), it is situated in the *il* (province) of Izmir in Turkey at the head of a deep gulf of the eastern Aegean, with the Hermus (modern Gediz) discharging on its northern shore. The little plain of Smyrna extends nine miles inland from the coast. The prehistoric and early Greek city of Smyrna lay at the northwest corner of this plain; after the time of Alexander the Great the city of Smyrna was built 3 mi. (5 km.) farther south at the southwest corner of the plain.

Old Smyrna.—The oldest settlement was on a low hillock (probably a peninsula in antiquity) by the modern suburb of Bayrakli. Anglo-Turkish excavations in 1948–51 revealed numerous strata of prehistoric habitation with remains of houses of

crude brick on stone foundations, the earliest occupation found being contemporary with that of the first city of Troy at the beginning of the Bronze Age (*c.* 3000 B.C.). In Greek tradition the pre-Greek city of Smyrna was ascribed to an Amazon foundress of the same name; to the Leleges; and to the legendary king Tantalus. It is not known whether Hittite dominion ever reached this far, but the weather-god Teshub seems to be portrayed in rock-relief in the Karabel pass 10 mi. S.E. of the plain of Smyrna. Greek settlement is first clearly attested by the presence of pottery of the style called Protogeometric, dating perhaps from *c.* 1000 B.C. The Greek city of Smyrna is said by Herodotus to have been founded by Aeolians but seized by Ionic refugees from Colophon who barred the gates when the Aeolic inhabitants were out at a festival. Excavation has shown that from modest beginnings (single-room horseshoe-shaped huts with thatched roofs) Greek Smyrna grew into a stately city in the 7th century B.C. with massive fortifications and axially planned blocks of two-storied houses. Attacked by Gyges of Lydia in the early 7th century, Smyrna is said to have repelled the invasion; its citizens won fame for their exploits against the Lydian horsemen. But later the city fell to the Lydian king Alyattes; it may well have been this emergency that evoked the martial elegiacs that the poet Mimnermus addressed to the Smyrnaeans. After the Lydian capture Smyrna ceased to exist as a city and (as the geographer Strabo records) was inhabited in village fashion. It did not join the Delian league in the 5th century. The old town was not entirely depopulated, and in the 4th century it was again densely inhabited. Smyrna is mentioned as a wheat mart in a decree of 387 B.C. and is commemorated on a silver coin minted at Colophon about the same time. Above all it is remembered as the reputed birthplace of the poet Homer. Two ruined fortifications on the mountain above the old city have been thought to be relics of a remote epoch, but may rather be the mansion and outpost of a landowner or local despot of this time.

The New City.—Strabo says that Antigonus I and Lysimachus reestablished Smyrna (before and after 301 B.C.), but local tradition made Alexander himself conceive the idea of refounding the city on a visit there in 334 B.C., and the evidence of excavation at Old Smyrna seems to favour a date in his lifetime for the removal. The new city had its citadel on the flat-topped hill called Pagus, from which the two arms of the city wall descended to enclose the city and its inner harbour on the north; this closed harbour, which was partly filled in when Timur (Tamerlane) sacked Smyrna in 1402, is now wholly dry land and occupied by the bazaars. The visible ruins of the citadel are medieval but are built on ancient foundations in the southwest part. On the upper slope of the Pagus was the stadium and a theatre of Roman date. Excavations conducted by Turkish archaeologists have uncovered much of the agora (forum) at the foot of the slope; rebuilt (with the bounty of Marcus Aurelius) after the disastrous earthquake of A.D. 178, it was surrounded by two-storied colonnades, and it contained numerous statues and an altar with reliefs of the 12 gods. It is said that an avenue, called the Golden, traversed the city from east to west, running round the lower slopes of the Pagus. Built on these slopes and at their foot, with paved streets laid out on a varied rectilinear plan, ancient Smyrna was renowned for its beauty; the one fault attributed to its architects was that they did not lay down drains in the streets, so that the roadways were awash with filth in heavy rain.

Smyrna was for a short time known as Eurydicea in honour of Lysimachus' daughter. After Lysimachus' fall (281 B.C.) the city espoused the cause of the Seleucids and received Magnesia ad Sipylum as a reward for its services in 244 B.C., but it transferred its loyalty to Pergamum soon afterward and as early as 195 B.C. set up a temple dedicated to the city of Rome. It was a favourite place of exile for condemned Roman governors and legates. After Caesar's murder Trebonius was beheaded by Dolabella in Smyrna (43 B.C.), and the city suffered some damage; and Caesar's murderers, Brutus and Cassius, met there for their council of war. Smyrna was the centre of a civil diocese in the Roman province of Asia, and vied with Ephesus and Pergamum for the title "first [city] of Asia." It was chosen by the Roman senate for the honour of erecting a temple to the emperor Tiberius in A.D. 26. It was visited by Hadrian and Marcus Aurelius, and the sophist Apollonius of Tyana resided there. Smyrna had a considerable Jewish colony and was one of the early seats of Christianity; its church endured the tribulation predicted of it in the Apocalypse (Rev. ii, 8–11) by the martyrdom of its bishop Polycarp (A.D. 156 or 168) and of Pionius (A.D. 250).

The stream Meles, beginning and ending its brief course near the walls of Smyrna, was associated in local tradition with Homer, who was reputed to have been born by its banks and to have composed his poems in a cave near its source; the stream was celebrated in local literature and worshiped for its healing powers. Its identity has long been a subject of controversy; yet there can be no doubt that it is the stream that issues at Halkapinar (the so-called "baths of Diana") and forms a fishpond at the shore on the northeast of the modern city. Homer and Mimnermus were far the greatest poets associated with Smyrna; but the pastoral poet Bion and the late epic writer Quintus Smyrnaeus also deserve mention. The city was celebrated for its library, its school of medicine in which Galen studied, and a rhetorical tradition dignified by the names of Polemon and Publius Aelius Aristides. Its specialties included prawns, lettuce, vines that produced a Pramnian wine, malachite and white lead. It possessed thermal baths (probably those at Balcova southwest of the city) named after Agamemnon, who was said to have halted there to treat his wounded men. The tutelary deity of ancient Smyrna was the Sipylene Mother.

Smyrna continued in Byzantine times as a metropolitan see, and was made the capital of the naval theme of Samos. Despite Arab attacks in the 7th century and its capture by the Turkish raider Tsacha (Tzachas) in 1090, Smyrna was still a great city when the Norse pilgrim Saevulf put in there in 1103. Its ruined citadel was rebuilt by the emperor John III Vatatzes *c.* 1225. By the treaty of Nymphaeum in 1261 Michael VIII Palaeologus ceded the flourishing port of Smyrna to the Genoese, reserving only Greek ecclesiastical autonomy. As the result of Byzantine military and naval disarmament in the east, Turkish ghazis with their hordes broke through the Seljuk state of Rum (Iconium) and established principalities in western Asia Minor. Perhaps as early as 1317 the amir Mohammed of the Aydin dynasty captured the citadel of Smyrna; and despite the prolonged resistance of Martino Zaccharia, Mohammed's son Omer became master of the city in 1329 and established his naval station there in that year.

It may in conclusion be remarked that, after Athens, Smyrna is second to none of the cities of the Mediterranean world in its continuous historical importance during the last 5,000 years.

SMYTH, JOHN (d. 1612), a pioneer in the demand for liberty of conscience, who "may be regarded as the father and founder of the organized Baptists of England" (A. C. Underwood); he also influenced the Nottinghamshire Separatist group of which some later emigrated to New England as the "Pilgrim Fathers." His origins are obscure. He matriculated in 1586 at Christ's College, Cambridge, where he was a fellow during 1594–98. From 1600 to 1602 he was city preacher at Lincoln, but in 1606 he renounced his episcopal ordination and became minister to a group meeting in separation from the Church of England at Gainsborough, Lincolnshire. For two years he and John Robinson (*q.v.*), of Scrooby, Nottinghamshire, "provided the necessary leadership and theological equipment" (R. A. Marchant) for organized Separatism in this district. In 1608 both men, with their followers, left England for Amsterdam, where they soon parted. Smyth adopted Baptist principles and baptized (by affusion, or pouring water over the head, not immersion) not only Thomas Helwys (who later became a Baptist pioneer in London) and other members of the congregation but, first, himself. As he received fresh light, Smyth continually altered his convictions, and unashamedly: "wee are inconstant in erroer." This inevitably caused
